THE results obtained from the growing of Cucumbers in frames are, in the main, far from the maximum obtainable, for a good frame is capable of affording ideal conditions for the cultivation of Cucumbers, and it is the purpose of these notes to give a few hints which may help those who do not get satisfactory results.

To attempt cultivation so early in the year as the present, a heated pit or a good hot-bed is essential, but from mid-May onwards, heat and hot-bed may be dispensed with, and the sun may be relied upon to produce the necessary warmth. If a hot-bed is used, a very small quantity only of good loamy soil is sufficient to start the young Cucumber plants in, but if no bed is used, a mound, about a foot high, built up of layers of loam and strawy manure, should be made, and the planting done in this. It is generally recommended that a plant be placed in the centre of each light, pinching the tip of the main growth back to encourage the production of laterals, which are then disposed over the frame area. In this respect the plants are treated differently from those grown in the Cucumber houses, where the leader is encouraged to run up quickly to the full extent of the roof. This latter method allows the orderly pinching and placing of laterals and subsequent shoots, and is to be preferred. It may be carried out in frames by placing the plant at the back of the frame instead of in the centre. Two plants are needed for a four-feet light, and the leader is run straight down the full length of the frame, stopping it at the end, the laterals being stopped at the second leaf and subsequent growths at one leaf.

Cucumbers should be planted in a small quantity of soil, and frequent top-dressings given as the roots emerge from the surface. If Cucumbers are planted as I suggest, top-dressing will be found to be a much simpler matter than if it had to be done to a plant in the centre of a light, where stems radiate in every direction, and a mass of leaves cover the root-system. In the same way watering is facilitated. Frequent waterings and continuous top-dressing with loam, so much beloved by Cucumbers, often results in the mound becoming consolidated, a condition detrimental to growth, as well as rendering effective watering difficult. To obviate this, an occasional dressing of one inch of short straw, between the layers of loam, is quite effective. Care should be taken that, if the strawy layer is from the manure heap, and contains ammonia, it is completely covered with loam at once, or bad scorching will result from the fumes given off in the heat.

Shading and ventilation are vital matters; the best crops are obtained by affording sufficient shade to make ventilation unnecessary. The hotter the sun, the denser should be the shade. Clearly, the ideal condition is a shading that may be removed daily, so soon as a decline in the sun's power renders it advisable, but this is generally impracticable, and a more or less permanent shading is put on the glass. This may be made of whiting and sprayed on with a syringe. Such a shading will be washed off by the first rain, and is thus advantageous to the extent of being off when not required, *i.e.*, during a rainy spell. Care must be taken that it is renewed so soon as the bright weather returns, for an hour's sun will do great damage. A shading that will withstand rain may be made of flour. Personally, I give a light shading of flour, and during a hot spell have recourse to the temporary shade of whiting in addition. By following this practice, keeping the atmosphere moist, and the plants well watered, ventilation need not be considered.

Feeding is much appreciated by plants cropping heavily, and nothing seems to be more suitable than weak, clear liquid sheep manure. Soot-water is a tonic, and a sprinkling of slaked lime over the bed occasionally should benefit the plants greatly. When the first crop of fruits has been gathered, and the exhausted shoots have been cut out, it is a good plan to withhold water until the bed is nearly dried out. This will result in a flush of young shoots and renewed root action when watering is again practised.

It often happens that a few cold nights experienced when the plants are young, place the whole crop in jeopardy. Covering the glass is a great help, but a valuable additional safeguard is to fit a paper bag over each plant. This is worth doing as a matter of course with plants on a hot-bed, particularly if the bag is made to fit down closely over the entire mound of soil. It may be practised even in houses, and improved growth will be evident if they are covered nightly for a week. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

SOCIETIES.

DERBYSHIRE HORTICULTURAL.

AT the monthly meeting of the Derbyshire Horticultural Association, held at the Agricultural Institute, Derby, Mr. A. R. S. Proctor, F.L.S., gave an interesting lecture on "British Alpines," illustrated by a series of lantern slides.

The lecturer described the conditions which led up to the present distribution of alpine plants in this country, and the part played by the climate, soil and exposure in maintaining or reducing their numbers. It is quite possible to grow many of these alpines in the rock garden, but certain kinds, such as Dryas octopetala, need careful attention to their ecological requirements, before success is obtained. There are a few sub-alpine species still retained in the Derbyshire flora, but for the most part we must turn to the high mountains of Cumberland and Wales, and the Scottish Bens, although the highest peak, Ben Nevis, is particularly poor in alpine species, due to the great stretches of inhospitable granite boulders.

The slides revealed a great difference on the rock ledges of Ben Lui, in the west, and Glen Clova, in the east, where, amid heavy precipitations, very low temperatures far into the summer, and on a rich, porous soil, the alpines grow in wonderful luxuriance. It is, however, in the corries and on the rocky ledges of the Breadalbane mountains that these plants reach their optimum in Britain. Here may be found, among many others, several rare Saxifrages, Veronicas, the mountain Erigeron, and, in places, great masses of the alpine Myosotis, whose intense blue is only surpassed by that of the Snow Gentian at the foot of the rocks.

Most of these plants, except the Gentian, which is an annual, can be grown in the rock garden with, perhaps, only a loss of colour intensity, but it is most undesirable that any should be taken from their natural surroundings, as they are fighting a losing battle as it is with the climatic conditions, every hot summer reducing their numbers, while every one dug up by the collector hastens the day of their extermination. This, however, does not prevent gardeners enjoying these treasures in their own gardens, for seeds of most of them may be procured from firms which cater for this type of plant, and although some are slow in germination, this is certainly the method recommended.

Mr. L. Smith, Derby, proposed a hearty vote of thanks, seconded by Mr. A. H. Harrison, Melbourne, supported by the Hon. Secretary, Mr. W. Wardman.

BATLEY PAXTON.

THE Annual Dinner of the Batley Paxton Society was held at Wilton Arms Hotel, on Thursday, February 14. Mr. J. Rhodes presided and among those present were Mr. J. Schofield (Chairman of Committee), Mr. A. Jennings (Treasurer), Mr. J. F. Stubby (Secretary), Mr. J. W. Bray (Corresponding Secretary), members of the Committee and Messrs. H. Fordham (Wakefield Society), C. F. Pragnall (Leeds), Horne (Bradford), and F. Sanderson (Huddersfield). Appreciated musical items were given by Messrs. H. Jennings, F. Jennings and J. H. Jennings.

Proposing "The Society," the President stated that good progress was being made; they had a record membership and fine attendances at the winter lectures, which commenced two or three weeks ago. Various subjects were dealt with and helpful discussions followed. He thought great good would result. He was very sorry their ex-President, Mr. Arthur Kemp, was ill and unable to be present. The November show was stated twenty years ago to be the best one-day show in Yorkshire, and he thought last year's show proved it still maintained that reputation. They had a record exhibition of Chrysanthemums, and donated £11 to the local hospital. A new schedule had been adopted for this year, and many supporters had come forward with generous offers to provide prizes;

one local gentleman offering a Rose bowl for competition and others special prizes.

"Kindred Societies and Visiting Friends" were toasted by Mr. Schofield, who said they were indebted to fellow Paxtonians for help, and proud of their association with the professional men connected with the Leeds, Bradford and Wakefield Societies. Mr. Fordham offered the Wakefield Society's best wishes for Batley's success. Wakefield celebrated its jubilee two years ago, and he was glad to note the Batley Society had passed its forty-first year. Wakefield's jubilee celebrations lasted three weeks. The first week they had a trip to the Yorkshire dales, the following week a dinner, and the third week they planted trees in Wakefield Park on a triangular plot of land allocated by the Corporation and now called "Paxton Corner."

BRITISH MYCOLOGICAL.

A meeting of the British Mycological Society was held at University College, London, on January 26, with Miss E. M. Wakefield, President, in the chair. The first paper was by Dr. Alex. Smith on "Some Observations of Puccinia Menthae."

Examination of infected plants of the common garden Mint from a variety of sources has failed to confirm the presence of a perennial mycelium for the aecidial stage of the rust, Puccinia Menthae. It is concluded that if a perennial mycelium does occur, it is too infrequent to be of any significance in the life history of the fungus. The mycelium is confined to the hypertrophied area and its immediate neighbourhood, and does not proceed to the underground portions of the plant.

Infection takes place in late autumn, during winter, and probably also in early spring, whenever the weather is sufficiently open and young Mint buds are showing above ground. Under experimental conditions good results were obtained from inoculations made with germinating teleutospores, from early November up to Christmas. Successful infections, both naturally and artificially produced, could, in some seasons, be detected as early as mid-January. Infection of fresh growth at the tops of old shoots in autumn has been shown to occur in October and November, proceeding presumably from early germination of teleutospores. Normal aecidia on hypertrophied shoots resulted. Investigation showed that the mycelium of these infected shoots was not connected with mycelium in the main stem.

Hand-picking of infected shoots gave no obvious control. Burning straw on the infected bed in September and early October gave very considerable reduction, and in some cases complete elimination, of the disease. The most satisfactory method of control has, however, been found to be in the establishment of fresh plantations free from the disease. This may be best secured by digging up underground stems in September and removing from them all above-ground portions. After washing under a tap or hose-pipe to remove adherent earth and spores, they should be planted as remotely as possible from infected plants. As an additional precaution the bed from which stock is to be taken may be blazed with straw, even although it is to be destroyed later.

The needs of the Mint-forcing industry have not yet been investigated, but this latter method should, with modifications, prove suitable, although the establishment of healthy stock beds, as outlined above, should be the ideal. The rust of the Peppermint has not yet been investigated.

Miss D. M. Cayley followed with a paper on "Some observations on the Genus Didymium (Mycetozoa)." Some observations on the conditions conducive to the production of sporangia by several species of Didymium, when grown in culture, were discussed, more especially with regard to D. difforme. The process of fusion of the gametes in the motile swarm spore stage in this species, as seen *in vivo* under the microscope, both in mono- and multi-spore cultures, was described. The observations, together with further experimental proof of the development of sporangia in three successive generations of mono-spore cultures grown on a synthetic medium, were brought forward as evidence of the bisexuality of the spores, as against the assertion of unisexuality made by Skupienshi in a recent publication. Our present knowledge of the meiotic division before spore delimitation in the mycetozoa was reviewed and criticised. Only two or three authentic cases of typical meiosis before spore formation are known, namely, Ceratiomyxa fructiulosa, Reticularia Lycoperdon and, possibly, Dictyostelium mucoroides, giving rise to spores which are definitely haploid. In all the other species of Endosporae which have been investigated cytologically, only one division is recorded, held by some investigators to be a reduction division. The inadvisability of assuming that the reduction process can be completed in a single division, and that the resulting spores are haploid, until further evidence is to hand, was emphasised.

The next paper was on "An Investigation of the Metabolism of Nematospora Gossypii, Ashby and Nowell," by Miss E. Helen M. Farries.

Among the "Fungi of Stigmatomycosis" there exists an interesting range of specialisation as regards their nitrogen metabolism. Nematospora Gossypii (Tanganyka strain) is the most highly specialised of the group; it will grow on a complex source of nitrogen, such as peptone, but it will not grow on asparagin and inorganic salts. Experiments have been carried out to determine upon what this specialisation depends.

The complex molecule of peptone is not essential, for the fungus will grow equally well upon the mixture of amino-acids derived from acid hydrolysis of peptone; and to a lesser degree upon the hydrolysis products of casein, white of egg, and gluten. Nitrogen substances essential for growth are, however, absent from the amino-acids of gelatin, and from synthetic mixtures of pure amino-acids. Growth on the two fractions of hydrolised peptone, *i.e.*, basic amino-acids and "acid" amino-acids, suggests that certain impurities in the commercial peptone may be valuable. This hypothesis is supported by the fact that the fungus would not grow on the hydrolysis products of a highly purified albumen. Such work may throw light upon the complex question of the physiology of obligate parasitism.

Mr. M. Mitra then gave an account of a species of Phytophthora causing damping-off of Cotton seedlings, and a "fruit rot" of Guava in India. Inoculation experiments confirmed the morphological identification that the fungus causing the appearance of irregular, water-soaked patches on the cotyledons and first-formed leaves of Cotton seedlings, and that producing a rotting of Guava fruits very similar to the "Cottony Leak" of Cucurbits, are both Phytophthora parasitica, Dast.

The last paper was by Professor A. Chaston Chapman, on a new species of Oidium; read in his absence by Mr. J. Ramsbottom. The fungus grew in a sewer connecting a factory with the main sewer of the town, and increased so rapidly that the sewer soon became almost blocked. The sewer was used for conveying the factory effluent to the lower sewer, and was jointed at a certain point by a side drain conveying a very small quantity of domestic sewage. Fungal growth always began just below the point at which domestic sewage entered and from here onwards developed into a hard, gelatinous mass which ultimately blocked the sewer. Experiments showed that the mould grew slowly in the factory effluent alone, but rapidly when a little nitrogen was added in the form of sterilised domestic sewage. This explained the fact that the mould did not develop in the factory sewer until the point was reached at which the domestic sewage entered, the necessary carbon being supplied by sodium acetate in the factory effluent.

GUILDFORD GARDENERS'.

On February 12, Mr. N. Cook, of Reading, visited this Association and delivered a lecture on "Pests of the Kitchen Garden."

By way of preface to the lecture, Mr. Cook conveyed friendly greetings from the Reading Society, and in doing so paid a few graceful compliments to the Guildford Association, and the work of its sub-committees, with special reference to the valuable assistance rendered by the lady members. Mr. Cook stated there is no sovereign remedy for the various garden pests; they cannot be wholly destroyed, and many forms of insect life are proof against winter and summer weather, however severe. All that can be done is to use preventives. In the first place there should be no indiscriminate destruction of birds. In the spring, even the queen wasp is a friend, therefore early autumn, not spring, is the time for wasp extermination. He did, however, advocate the giving of prizes for netting the Cabbage White butterfly, which is a pest altogether and serves no useful purpose at all. A great many palliatives were suggested by means of which pests could be kept down, but stress was laid on the necessity of growing healthy plants. It is the weaklings among plants, as among animals, that are attacked first; a strong, healthy plant is likely to resist attack where a weakling will succumb.

To attain this end, a little stimulation was recommended for plants in the very early stage of growth. When the food stored in the seed is used up, and before roots are properly formed, the seedling needs helping over a dangerous stage. Too much stimulant would promote soft growth, and so defeat the object in view. In dealing with this aspect of pest control, Mr. Cook gave many hints on the care and culture of commonly grown vegetables.

CARDIFF GARDENERS'.

The fortnightly meeting of the above Association was held at The Queen's Hotel, Cardiff, on February 26, Mr. W. Bennett presiding. Owing to the inclement weather, the attendance was not so large as usual. The lecturer for the evening was Mr. Childs, the Newport representative, and his subject was "Planting a half-acre Orchard with Standard Apples." The lecturer dealt with his subject in a most practical manner, laying stress on the importance of draining the land if this was at all low-lying or inclined to be wet. His method of planting and dealing with the trees afterwards was quite sound, and a diagram he produced indicated his proposed Apples in their respective positions, which showed he was an advocate of mixing his dessert and culinary kinds in a typical manner. The varieties of Apples he recommended called for some discussion.

There was a splendid display of Narcissi for prizes given by Mr. W. Webber, the first being awarded to Mr. C. Franklin; second, Mr. W. Bennettt; and third, Mr. J. Jones. For the best nine blooms of Perpetual-flowering Carnations, Mr. F. Baker secured the first prize, and Mr. Hardwick second. For the best three dishes of Rhubarb, Mr. Franklin was first, and Mr. H. Jenkins second.

Among competitors for points, Mr. J. Jones secured the maximum number, and an Award of Merit for a grand specimen of Coelogyne cristata. The maximum number of points was also awarded to Mr. Baker for an excellent dish of Lily White Seakale, and to Mr. Jenkins for a well-grown bowl of Tulips.

The next meeting will be held on March 12, when Mr. H. R. Farmer, of Cardiff Castle Gardens, will lecture on "Jam-making and Fruit Bottling." Ladies are cordially invited to this meeting.

TRADE NOTES.

In untrained hands, the indiscriminate use of fertilising chemicals for lawns and greens can be a perilous and even a costly undertaking; the green-keeper will therefore be well advised to seek such guidance as is given in the booklet issued by Messrs. Joseph Fison and Co., Ltd., of Ipswich. This is a manual upon the preservation and maintenance of every kind of grass.

Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle.*

ANSWERS TO CORRESPONDENTS.

BASIC SLAG FOR SPORTS GROUND.—*A. J. G.* Basic slag may be applied to a sports ground at the rate of three ounces per square yard in winter or early spring, but its effect is to encourage the growth of Clovers at the expense of grass. It only supplies phosphoric acid to the plant, however, and if your sports ground is nearly exhausted, we suggest that a quicker acting and complete manure would be more suitable for application this spring. If your soil is of a heavy nature, apply a mixture of one part sulphate of ammonia and two parts superphosphate at the rate of two ounces per square yard. If the soil is light and sandy, add one part of sulphate of potash to the mixture, thus making it a complete fertiliser, and apply at the rate of two ounces per square yard. In either case, if the mixture is mixed with three or four times its volume of sifted leaf-soil, it will facilitate uniform distribution and be of benefit to the grass.

BROMPTON STOCKS DISEASED.—*H. W.* The Brompton Stocks are affected by one of the foot-rot fungi. There is a chance of saving many of the plants by watering the soil with Cheshunt compound.

CARNATIONS UNHEALTHY.—*J. R.* The root systems of the Carnation plants are very unhealthy but no pathogenic organisms were discovered on the plants. The trouble may be due to high temperature, over-watering or excessive feeding.

CINERARIAS FAILING.—*D. F.* The Cineraria plant showed no evidence of attack by fungi or insects. The failure may be due to fumes from coal gas or from oil stoves. Trouble similar to this is often experienced where there is a great fluctuation between day and night temperatures.

CHRYSANTHEMUM RUST.—*E. H.* The Chrysanthemum foliage is suffering from an attack of rust, due to the fungus named Puccinia Chrysanthemi. The disease is carried by wind-blown spores and by means of cuttings and old stock plants. The plants should be dusted with flowers of sulphur as a preventive and careful attention should be paid to the selection of stock, ventilation and watering.

FUCHSIA ARBORESCENS.—*G.* Your plant is Fuchsia arborescens, a native of Mexico. It requires greenhouse treatment, but might withstand the winter in favoured localities in the west and south-west districts.

HYACINTHS FAILING.—*F. J.* It is apparent that the soil is not particularly suitable for Hyacinths, as, although they started to root fairly well, the roots died at a later date. But the failure is not wholly due to unsuitable soil. It is obvious that in many cases the bulbs were not of first-grade quality, and could not be expected to produce first-rate spikes.

NAMES OF PLANTS.—*G. B.* 1, Eupatorium riparium; 2, E. Weinmannianum; 3, Osmanthus aquifolium var.—*J. A. E.* 1, Cistus albidus; 2, might be a Helianthemum; 3, Coleonema album; 4, resembles Jacobinia pauciflora (better known as Libonia floribunda), but possibly only imitative; 5, resembles Lonicera pileata very closely; 6, Senecio laxifolius, so far as leaves are concerned. Seedlings are not very reliable for naming, because they are liable to change somewhat as they get older.

PROPAGATION OF STATICE PROFUSA.—*W. A. T.* This plant is best propagated by means of cuttings, which should be inserted during the spring, sometime during March being suitable. Some of the smaller shoots should be selected for cuttings, those about four inches in length being of suitable size. They are best inserted singly in small pots, using a light, sandy compost; after watering in, the cutting pots should be plunged in a close propagating case, in a cool greenhouse; if slight bottom-heat is available it will hasten rooting. As cuttings of this plant take rather a long time to root, care must be exercised in watering and in the general management of the propagating case. Good results may also be obtained by inserting the cuttings in a sand bed and covering them with a handlight or bell-glass.

Communications Received.—R. F.—A. G.—R. E. A.—G. F. W.—A. P.

Obituary.

W. Camm—We regret to announce the death of Mr. W. Camm, for so many years gardener to Lord Astor, at Cliveden—the magnificent garden and estate above one of the loveliest reaches of the Thames. Mr. Camm was a most capable gardener, modest to a fault; indeed, had he cared to do so, he could have been a prominent personality in the horticultural world, but his love for the garden he managed so ably was so great that he rarely left it. Those who knew him best had a great affection for him, as he was generous, humorous, kindly to his staff, and a gardener of exceptional skill. Fruit-growing was his speciality, but this was not allowed to overshadow his cleverness in flower gardening, or his management of the trees and shrubs in the famous garden over which he presided for a very long period. Mr. Camm had been ailing for some time past and he passed away in Windsor Hospital on Wednesday, February 26.

John Courtney.—Many of his old friends will be sorry to hear of the death of Mr. J. C. Courtney (age sixty-five years) which occurred on February 28, at Zoar Villa, Piddletown, Dorchester. He retired from the position of Gardener at Ilsington House, Piddletown, five years ago, through ill health. He was well-known about twenty-five years ago as Orchid Grower to the late Colonel Brymer of Ilsington, uncle of the present owner, when he exhibited Orchids at the R.H.S. and west of England shows. Cattleya Brymeriana, Dendrobium Brymerianum, Laelio-Cattleya Ilsingtonensis and Thunia Brymeriana, are a few of the Orchids raised by him. The collection was sold after the death of Colonel Brymer. The funeral took place at Piddletown Church on March 4 (the "Weatherbury" of Thomas Hardy's novel *Far From the Madding Crowd*) where he officiated as sidesman for a goodly number of years.

B. A. Plemper van Balen.—It is with very great regret that we have to record the death at Utrecht on February 17, of Mr. Plemper van Balen, a well-known horticulturist of Wageningen, Holland, and a very constant and faithful reader of our journal. He was one of the old school of Dutch nurserymen; born at Wageningen in 1857, he early showed a taste for horticulture, and became an apprentice in the then famous nursery of Glym de Vos, at Utrecht, afterwards gaining further experience at Ghent and in Germany, and eventually becoming gardener to King William III of Luxembourg. Later on he was appointed Curator of the Amsterdam Botanic Gardens, but in 1896, when the new horticultural school was established at Wageningen, Mr. Plemper van Balen became a lecturer in the flower department, later on, when the Agricultural College was raised to the status of a "Hoogeschool," receiving an appointment on the staff. He took for many years a constant and active interest in horticultural affairs generally, but towards the end of his life enfeebled health compelled him to abandon active work, and in November, 1925, he wrote us in the excellent English he had at his command:—"Because of age and feeble health my turn has come to end my many years' subscription to *The Gardeners' Chronicle. Great thanks* for the always interesting and excellent weekly 'Chronicle of the Gardening World' I did receive so many years. Although he spent the last years of his life in enforced retirement, he leaves many warm friends, both in Holland and abroad, by whom he will be greatly missed.

NEW HORTICULTURAL INVENTIONS.

THESE particulars of New Patents, of interest to readers, have been selected from the Official *Journal of Patents*, and are published by permission of the Controller of H.M. Stationery Office.

Abstract Published.

The litter of trimmings occasioned by cutting the edges of lawns can be avoided by the use of a new device patented under No. 302,981, by Messrs. W. N. Marcy and W. H. Clarke, of D'Abernon Lodge, Leatherhead, Surrey. One of the blades of the hand-shears for trimming grass edges, etc., is provided with a pan of approximately semi-circular planform, detachably secured to the blade by the bolts and nuts, the floor of the pan being below the bottom edge of the lower blade. The floor slopes upwards towards the blade, and also towards the front and rear corners, to enable the pan to ride past obstructions. For similar reasons the wall of the pan is reversely curved at the front to provide a leading pointed portion. The bolts are of slightly less diameter than the holes in the blade through which they pass, to allow limited adjustment.

REMARKS.—Supplies have been steadily on the increase during the past week, and prices this morning showed a tendency to be lower than for some weeks past. Roses are now becoming more attractive, the varieties available being America, Columbia, Madame Butterfly, Golden Ophelia and Richmond. All Tulips sold freely at increased prices on Friday and Saturday last. La Reine and White Hawk continue to be the shortest in supply in this class, therefore prices for them remain very firm. More double varieties, in fine condition, are on sale, the principal sorts being Murillo, Couronne d'Or, Peach Blossom, Lucretia and Red Rose. Darwin Tulips are also much finer in quality, William Copland, Bartigon, Elizabeth, William Pitt and Rosy Red being the sorts available. Daffodils are on the increase from all sources; the principal sorts from home-growers are now Emperor, Golden Spur, Victoria, Princeps, Sir Watkin, King Alfred and Lucifer. Larger consignments of Daffodils are expected this week from the Channel Islands. Narcissus Grand Primo, White Pearl and Cornish White meet with a good demand owing to the scarcity of other white blooms. St. Brigid Anemones and A. fulgens, Snowdrops, single Violets and Freesias have increased in quantity. Primroses are the latest arrival in this department. All foliage remains very limited in quantity and prices are still very high; the consignments are soon cleared. In the French department conditions are slightly inproved. Paper White Narcissi are finished, but more white Stocks were on sale this morning.

REMARKS.—We are glad to report rather better conditions than have been ruling lately. Probably spells of sunshine have had a stimulating effect on the trade. Comparatively large supplies of Peaches, Grapes, Nectarines, Plums and Pears are arriving from the Cape, and there is a slightly better tendency towards fruit selling, although Pears are not selling too freely, having to meet the competition of Pears from America. Arrivals of Apples from the North American continent are not so heavy and values are inclined to be firmer. Some fine English Bramley's Seedling Apples are now being marketed, and selling well. A few Bismarck and Newton Wonder Apples are also available and realising fair prices. The inquiry for Oranges remains firm, probably due to the large amount of illness prevalent.

Forced Beans are easier in price, but do not sell particularly freely. The shipment of Madeira Beans this week was in good condition and sold well. Hothouse Potatos are a moderate trade, and those from the Azores are selling well. Asparagus from France, although quoted easier, is still comparatively costly, the cold weather having restricted supplies. There is little or no improvement to report in the demand for Canary Island Tomatoes a few really good grades sell moderately well, but there are far too many indifferent grades, which sell badly. Mushrooms remain a steady trade, with practically no fluctuation in price level. Some fairly large quantities of Broccoli from northern France and also from Cornwall are meeting a good reception from buyers. French salads continue in good demand, but are not very plentiful. Green vegetables are, of course, scarce, but even so, not particularly dear. The Potato trade is better and first-grade varieties are quoted at advanced prices.

GLASGOW.

The return of the frost, with all its former severity, was reflected in the condition of the cut flowers from the Continent and the south of England. Tulips probably suffered most, and prices were generally easier, Bartigon William Copland, Le Notre. Couronne d'Or, William Pitt and Princess Elizabeth realising from 10d. to 1s. 4d. for 6's; Peach Blossom, Lucretia, Flamingo, La Reine, Tea Rose, Murillo and Prince of Austria, 8d. to 1s. 2d. and Cardinal, 9d. to 1s. Daffodils were also cheaper King Alfred being worth 1s. 3d. to 1s. 6d. per dozen, and Emperor, Sir Watkin and Victoria, 1s. to 1s. 3d.; Golden Spur, 9d. to 1s. 3d.; Princeps, 6d. to 9d.; Ornatus, 5d. to 8d. White Hyacinths sold at 6d. for 3's; Carnations 2s. to 6s. per dozen; Red Roses, 12s.; Lilium longiflorum, 10s. to 12s.; Richardias, 10s. to 15s.; Muscari, 6d. to 9d. for 6's; Lily-of-the-Valley, 2s. 3d. to 2s. 6d. per bunch; Anemones, 1s. 6d. to 1s. 9d.; Freesias, 1s. 6d.; Wallflowers, 4d.; Ranunculi, 2s. to 2s. 6d.; Myosotis, 1s. 3d. to 1s. 9d.; and Mimosa, 16s. per cane. Locally-grown special blooms of Emperor and Victoria Daffodils realised 9d. to 10d. for 6's.

Trade in the fruit market was quiet. Valencia Oranges fluctuated between 17s. and 25s., according to counts, while seedless brands made 37s. Apple prices were firm, Delicious, ex fancy, selling at 18s. per case; Winesap, 15s. Newtowns, 14s. 6d.; and Greenings, No. 1, 34s. per barrel. Blue Goose Grape Fruits were quoted at 26s. per case; bitter Oranges, 21s.; Lemons, 15s. for 300 and 360 counts; Pineapples, 3s. 6d. to 4s. 6d. each; home-grown Grapes, 4s. to 4s. 6d. per lb.; Cape Grapes, 12s. to 15s. (10 lbs.); Waltham Cross and White Hanneport Grapes, 10s. to 12s. 6d.; black and red Grapes, 10s. to 15s. Plums, 6s. per box; Nectarines, 4s. to 5s.; Peaches 4s. for 32's; and 5s. 6d. for 21's.

Vegetable prices were irregular. Cucumbers declined to 24s. per dozen; but Lettuces and Cauliflowers were firm at 4s. and 6s. 6d. respectively. Guernsey French Beans ranged in price to 8s. per lb.; Endive, 17s. 6d. per crate and Rhubarb, up to 48s. per cwt. Mushrooms were steady at 2s. 3d. per lb.

SCHEDULES RECEIVED.

SOCIETE NATIONALE "LES AMIS DES POIS DE SENTEUR."—Sixth National Exhibition of Sweet Peas (with International Section), in the Botanic Gardens, Brussels, on Saturday, Sunday and Monday, June 29, 30 and July 1, 1929.—Secretary, G. Bodewijn, 61, rue de la Démocratie, Sanderlecht-Brussels.

INSTOW SPRING FLOWER SHOW.—Exhibition in the Rifle Hall, Instow, on Wednesday, April 3, 1929.—Secretary, Miss Hinchliff, Worlington House, Instow.

TEWKESBURY AND DISTRICT DAFFODIL AND SPRING FLOWER SOCIETY.—Exhibition, in the Town Hall, Tewkesbury, on Thursday, April 11, 1929.—Secretary, Mr. J. S Gannaway, Newtown, Tewkesbury.

GARDENING APPOINTMENT.

James Birkett, for the past twelve years Gardene to Alderman T. E. HIGHAM, J.P., Bank House Accrington, as Gardener to Alderman R. H. POSNETT, J.P., The Mount, Runcorn, Cheshire. [Thanks for 2s. for R.G.O.F. Box.—EDS.]

CATALOGUES RECEIVED.

SUTTON AND SONS, Reading.—Farmers' Year Book Root Seeds, Grass and Clover Seeds, Agricultural Fertilisers.

R. F. CALVERT, Coverack, Cornwall.—New and Choice Daffodils.

MAXWELL AND BEALE, Broadstone, Dorset.—Heathers and Dwarf Rock Garden Shrubs.

BARR AND SONS, Covent Garden, W.C.2.—Hardy Perennials, Rock Plants, Alpines, Aquatics, etc.

J. CHEAL AND SONS, LTD., Crawley.—Dahlias, etc.

Foreign.

JOHN TELKAMP, Haarlem, Holland.—Bulbs and plants for summer bedding.

AYRES' NURSERY, Cape Town.—Bulbs.

Royal Horticultural Society's Accounts for 1928.

THE recently issued accounts of the Royal Horticultural Society for 1928, to which we referred briefly in our issue for February 23 (see p. 153), present some interesting points of comparison with those of the previous year, as well as some novel features which doubtless owe their origin, mainly, to the Society's recent outlay on bricks and mortar or, to be correct, reinforced concrete. The latter is doubtless responsible for the drastic reduction of the General Reserve Fund and of the Society's investments. The former, which stood at £37,600 in 1927, after touching high-water mark at £68,000 in 1926, is reduced to £5,049 10s. 0d. (cost), while the investments, which cost £45,841 0s. 6d., have been converted into cash, except £9,618 6s. 4d. worth of the three-and-a-half per cent. Conversion Loan of 1961. All the Society's investments were in trustee stocks, most of which were bought many years ago, and the loss on the sale of these stocks is entered at £2,087 5s. 4d. At the end of last year the total of the Society's "liquid" savings had been reduced to £14,667. Of the Society's funds, £84,000, in round figures, was spent on the new hall during 1928, making the total expenditure under that head to December 31 last £144,575 7s. 8d. Outlay in the new hall first appeared in the accounts of 1925, when £150 was charged to it, and for some time before that the Society had been putting money by for the purpose. Next year the figure had risen to £13,809 odd. In 1927, when building commenced in earnest, the expenditure had risen by £46,245 to £60,000 odd. Of the capital outlay on the new hall, a little short of £20,000 has been allocated to the plant for the new restaurant, its equipment and furnishing. The sale of the majority of the stocks in which the Society's savings were invested does not, of course, represent a loss of these savings. It is a transfer of the savings from their old form of "liquid" securities into a building, and in this new form the investment may possibly prove more remunerative than in the old. None the less, the building up of a liquid reserve fund will no doubt be resumed at the earliest moment; it was rightly a point to which paramount importance was attached by the late Rev. W. Wilks, to whose sagacious management the Society largely owes its present prosperity. As is inevitable in the case of a growing society, the establishment charges at headquarters show an increase which amounts to about ten per cent. on last year. The expenditure on the *Journal*, however, shows a reduction of £172, which coincides with an increase in the advertisement income of nearly £250. Economy seems to have been exercised in the purchase of books for the Lindley Library—a point on the wisdom of which there will be difference of opinion. There has been a drastic pruning of the expenditure on awards—prizes, cups and medals—which shows a saving of £565 on the previous year's outlay. During the year nearly £500 was expended on furnishings in the old hall and the offices, and there is an allocation of £88 17s. 0d. for a herbarium, which is presumably that which has been established at Vincent Square for hardy fruits. Last year saw a remarkable drop in both the expenditure on the Spring Meeting (Chelsea Show) and the receipts. The outlay fell by no less that £3,326 below that of 1927, to a few shillings short of £1,700, while receipts amounted to £1,011, showing an apparent loss on the Show of £687. It would be interesting to know how the saving in expenditure was effected, as there were no very obvious signs of a tightened purse at last year's Chelsea Show. In 1925 there was a profit on the Show of £673. In 1926 the profit rose to over £2,000, while in 1927 it was £1,644. Now that the Society has a sufficiently large hall of its own, the annually recurring outlay on the rent of an outside hall for the Autumn Show will disappear. In 1927, when the Autumn Show was held at the Holland Park Skating Rink for the last time, it cost the Society about £400, and, apparently, it has also been conducted at a loss. Of non-recurring items in last year's accounts, £400 is included as the cost of opening the new hall with befitting ceremony, and the International Exhibition of Garden Design depleted the Society's coffers by £2,630. That may, perhaps, be regarded as the cost of the inevitable "house warming." The item for "gratuities" has been swollen by £730, and if the major part of the increase is due to the honorarium voted to the late Mr. F. Reader on his retirement from the staff, none will grudge it. A new feature of the accounts is the inclusion of a profit and loss account for the restaurant and for the *Botanical Magazine*. The figures for the former are for the brief period from October 17 to November 30, 1928, and show a probably inevitable loss on the preliminary six weeks of £814. The *Botanical Magazine* is, we are glad to learn, self-supporting. Since it was built, the letting of the Vincent Square hall has been a substantial source of revenue to the Society, and after remaining fairly constant for some years at about £3,500, the revenue from this source rose suddenly last year to £4,179 nett. No doubt, during the present year the letting of the new hall will add materially to the Society's income, and it does not seem unreasonable to hope for a return of at least £10,000 annually from the letting of the two halls. In itself that will be no mean return on the Society's capital. The ground rent on the new hall is £1,200 a year. The balance sheet for the Wisley Garden is now over £15,000, and during 1928 there was an increase under various heads of expenditure and minor savings under others in comparison with the previous year. Salaries are more by over £500, labour by £655, and £629 has been spent on laboratory apparatus. Miscellaneous expenses are £400 up on the year. On the other hand, the income shows but a small increase, and excess of expenditure over income was, as stated in our issue for February 23, £12,000—the equivalent of a five per cent. investment on £240,000. We hope the Council will see its way to give a résume of the Society's finances in its Report for 1929, and one which will enable the Fellows to make comparisons with receipts and expenditure of other years, without wading through sixteen pages of figures.

Frost, Heat and Drought.—Up to the present it would appear that the year 1929, following the general vogue, is endeavouring to break all records so far as the weather is concerned. For February beat all cold records since 1895, and, as if to make amends, last week-end was the warmest and sunniest experienced in England during early March since 1870. Combined with this, we have not had rain for several weeks and plant life is in a dry and parched condition. A fortnight ago skating was being enjoyed throughout the greater part of the British Isles; last week-end people basked in the sunshine on the banks of lakes and ponds still covered with ice. The full tale of the damage done in gardens during the severe February weather has yet to be told, but reports received so far indicate widespread havoc.

The Marking of Imported Rose Trees.—The draft of an Order in Council to require imported Rose trees to be marked with an indication of origin in accordance with the Merchandise Marks Act, 1926, has been laid before Parliament, as required by Section 7 of the Act. The text of the draft Order in Council appears in the Board of Trade Journal for March 7, 1929, and copies of the draft Order may be obtained through any bookseller, or directly from His Majesty's Stationery Office, Adastral House, Kingsway, London, W.C. 2, and branches.

Show in Aid of Studley College.—With a view to raising money in connection with the national appeal on behalf of Studley College, a show and sale of flowers, fruits, vegetables and dairy produce is to be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on April 25. The show will be opened by Princess Mary at midday.

Gladioli in New England.—The New England Gladiolus Society and the British Gladiolus Society appear to be engaged in friendly rivalry over the popularisation of Gladioli. The American Society, of which Mrs. A. C. Scott, of 93, Grant Street, East Weymouth, Massachusetts, is the Secretary, has issued a publication entitled "Advancement in Beauty," dealing with the work of the Society, containing many special articles and brightened by numerous illustrations in colour and half-tone, and although several of these appear to be in the nature of *quids pro quo* to advertisers, that does not detract from their interest and beauty. The principal articles include a discussion of "Colour Standards," by Dr. S. I. Moody; "Gladiolus Breeding," by J. A. Kemp; a report of the Society's Demonstration Plot, by Clark L. Thayer; Gladiolus Species, by F. Lazenby; and Gladiolus Characteristics, by

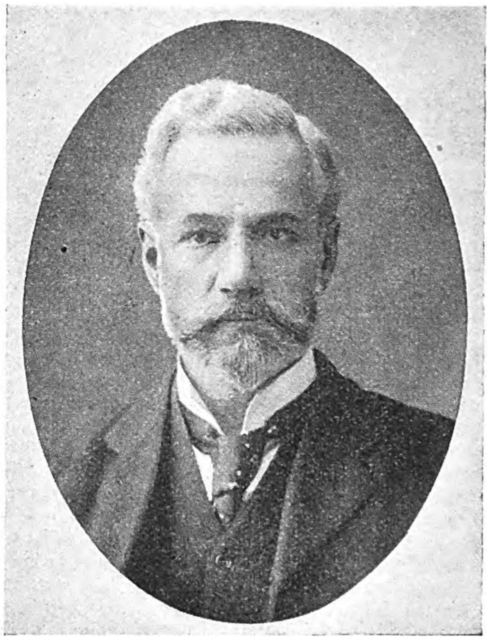
A. M. S. Pridham, of Cornell University. The exhibition held in August, 1928, is reprinted and illustrated. The double-page centrepiece of the book is a pleasing illustration of a new Gladiolus named The Orchid, this is pink and buff, with wavy segments; the raiser of this variety does not suffer from excessive modesty as he states (in the advertisement columns) that "millions will be demanded so soon as they can be produced."

Jubilee of a Horticultural Journal.—On March 16, *Gardening Illustrated,* the property of Messrs. Benn Bros., Ltd., Bouverie House, attains its jubilee. It was founded in March, 1879, by Mr. William Robinson, the doyen of English horticulturists, who also acted as its editor for thirty years. There are very few gardening papers which have reached the age of fifty years, and we heartily congratulate our contemporary. *The Gardeners' Chronicle* celebrated its jubilee in January, 1891, and will be celebrating its centenary in twelve years' time.

Legacies to Gardeners.—The late Mr. John Rowe Pope, J.P., of Trebartha, Wotton, Gloucester, who died on January 16, left £500 to his gardener, Mr. Clarke, if still in his service. —The late Rev. Sir John Caesar Hawkins, Bart., D.D., of Kelston Lodge, Banbury Road, Oxford, who died on January 18, left £20 and a life annuity of £52 to his gardener, Mr. Richard Miller, who had been in his service since 1863.

Retirement of Professor T. Echtermeyer.—For many years Director of the Prussian Training and Research Institute of Horticulture at Dahlem, Berlin, Professor T. Echtermeyer goes into retirement on April 1, 1929. He was born on October 23, 1863, at Marienburg, in West Prussia, and after completing his school education, took up gardening, attending from 1884 to 1886 the then Royal Institute of Gardening at Wildpark, near Potsdam. After a long and successful career at home and abroad, he was appointed in 1894 to the headship of the Wildpark Institute, which he continued to hold after its removal to its present quarters at Dahlem, and brought it, by his energetic and persevering endeavours, to the high position which it now enjoys. Professor Echtermeyer has a commanding personality, and has done much to assist the development and improvement of horticultural training in Germany. He was among the first to advocate the bringing into cultivation of waste lands, and to establish the small-holding colonies which have since proved so successful.

Gaultheria Hybrids in New Zealand.—Dr. A. W. Hill, Director of the Royal Gardens, Kew, exhibited a long series of Gaultheria hybrids at the recent meeting of the Linnean Society. The plants exhibited had been collected by Dr. Hill on Rainbow Mountain and Waimaro (North Island) and elsewhere, supplemented by specimens collected by Dr. Cockayne and others. These showed the gradual passage from Gaultheria oppositifolia to G. antipoda; from G. oppositifolia to G. rupestris, thence to G. perplexa, and a series of hybrids between G. perplexa and G. antipoda, and G. rupestris and G. antipoda. In connection with this remarkable series it should be noted that both G. oppositifolia and G. rupestris have a dry capsular fruit, and the calyx-segments do not become fleshy when the fruit ripens. In G. antipoda, however, the calyx becomes thick and fleshy as the seed ripens (although there is a well-matched form with a non-fleshy calyx), while in G. perplexa not only are the calyx-segments fleshy, but the fruit is a fleshy berry, exactly as in the genus Pernettya. The condition can be exactly matched in Pernettya Pentlandii from the Andes of South America. In G. oppositifolia and G. rupestris the inflorescences are terminal panicles and the stems are practically glabrous. The polyphormic hybrids with G. antipoda have the stems covered with strigose hairs, alternate leaves, and the flower arrangement varies from axillary panicles or racemes to solitary flowers in the leaf axils In some of the hybrids "fruits" were found with some of the calyx-segments fleshy and some dry in the same flower. In places where G. perplexa and G. antipoda (? G. depressa) grow together, as at Waimaro, it is very rare to find either species in the pure state. When G. rupestris hybridises with G. antipoda the progeny always shows a swollen, fleshy calyx. Most of the hybrid Gaultherias produce viable seeds. Gaultheria fagifolia, Hook. f., is one of the hybrid swarms of either G. oppositifolia × antipoda or of G. oppositifolia × rupestris. There is some evidence that the Gaultherias in Tasmania also hybridise, and G. lanceolata appears to be of hybrid origin.



MR. A. D. RICHARDSON.

Mr. A. D. Richardson. — No horticulturist is better-known in Edinburgh than Mr. A. D Richardson, who was born at Garvald, East Lothian, but was taken to Fifeshire when less than a year old. He received his early education at the parish school of Largo. His father had the management of the Largo estate for eight years, and then went to Midlothian to take charge of the Arniston and Polton estates of the late Sir Robert Dundas, Bart. At that time Arniston was one of the finest estates in Midlothian, its arboricultural features being of great interest, including some of the earliest planted Larches in Scotland. It was on this estate that James Brown was formerly forester, and where the first edition of his book, *The Forester*, was produced, in 1847. When Mr. A. D. Richardson left school, his ambition was to become a mechanical engineer, but lack of facilities compelled him to abandon the idea, and before he was fifteen, he had, under some parental pressure, to become an apprentice forester. Afterwards he gained experience of practical gardening, which then had a greater attraction for him than practical forestry. Many improvements were carried out on the Arniston estate, and it was in connection with these that Mr. Richardson acquired his first experience of practical landscape work, for which he further equipped himself by attending the three-months summer course in field engineering at the University of Edinburgh, under the late Professor Jenkin, and also, during the same period, by attending the University botany class at the Royal Botanic Garden, under the late Professor John Hutton Balfour. Mr. Richardson left Arniston and entered the service of a large public works contractor in Edinburgh, where he gained an experience which has been of great value in connection with the practical operations of landscape gardening. Early in 1880 he was invited by the late Mr. John Sadler, the Curator of the Edinburgh Royal Botanic Garden and arboretum, to become his general assistant, with special charge of the arboretum. At that time, the Arboretum —the land for which was purchased by the Edinburgh Corporation and transferred to the Government—was intended for a Scottish School of Forestry, and was placed under a separate Government Department from the Garden, and thus remained until the passing of the Scottish Universities Act, in 1888, after which both were placed under the administration of H.M. Office of Works. Mr. Sadler died in December, 1882, and was succeeded in the Curatorship by Mr. Robert Lindsay, who had been the general foreman of the Botanic Garden for many years. On the death of Professor Alexander Dickson, the Regius Keeper of the Garden, in 1887, the late Sir Isaac Bayley Balfour was appointed Regius Keeper of the garden and arboretum, and soon after his appointment the remodelling of both the garden and arboretum, which hitherto had been separate entities, was taken in hand, and the garden was also thrown open to the public on Sundays, as the arboretum had been from the first. This involved a complete rearrangement and reconstruction of the walks and grounds to accommodate the large crowds which visited the gardens on these days. Mr. Richardson became general foreman of the garden and arboretum, the present Curator, Mr. Harrow, being in charge of the under-glass department. In this remodelling, Mr. Richardson took a large part. Mr. Lindsay retired from the Curatorship in 1896, and was succeeded by Mr. Richardson, but in 1902, after a continuous service of twenty-tw years, he resigned in order to take up genera landscape gardening and advisory work, in which he has since been engaged. He became a member of the Royal Scottish Arboricultural Society in 1873, when an apprentice forester, and there are now but six members in the Society who were on the roll at that time. He took part in the first foreign excursion of the Society, to north Germany, in 1895, and subsequently to Sweden and France. His experience of the German excursion gave him, as it did to all the practical foresters present, an entirely new conception of what commercial forestry really meant, for at that time scarcely any of the practical foresters of this country had seen anything of Continental practice and methods. Mr. Richardson sub-edited the *Transactions* of the Society while the late Mr. John Nisbet was honorary editor, and also for some time during Colonel Bailey's honorary editorship. He also acted as Secretary and Treasurer to, and Editor of the *Transactions* of the Scottish Horticutural Association from 1906 until its incorporation by the Royal Caledonian Horticultural Society in 1921, a period of fifteen years, and served on the Councils of the Royal Scottish Arboricultural, the Royal Caledonian Horticultural and the Edinburgh Natural History Societies. Mr. Richardson was elected an Associate of the Edinburgh Botanical Society in 1883, and awarded the Neill Prize in Horticulture, as a botanist, in 1916—altogether a goodly record and one to be proud of.

Roses for Trial at Wisley. — The Director of Wisley asks us to remind raisers of Roses that six plants of each variety for trial should reach him at the R.H.S. Gardens, Wisley, Ripley, Surrey, by the end of March. Each variety requires an entry form, copies of which will be sent on application to the Director.

Variety and Cooking Trials of Potatos.—Since 1917, the Agricultural Department of the Lancashire County Council has conducted a series of trials to compare the yields and cooking qualities of important established varieties of Potatos with the more promising of the newer varieties as they appear. Six varieties were tried in 1928, these, with their average yield per acre being :—Kerr's Pink, 11 tons 4½ cwts.; Arran Victory, 10 tons 4¾ cwts.; Arran Consul, 9 tons 9¼ cwts.; Field-Marshal, 9 tons 2¼ cwts.; Ben Cruachan, 8 tons 8½ cwts.; and Majestic, 8 tons. A hundredweight of "seed" of each variety, from the west of Ireland, was planted at each of five different centres. Kerr's Pink is described as the most widely-grown maincrop variety in Lancashire, and is grown in these trials each year as a standard; in cooking qualties it is equal to Field-Marshal and King Edward, and second to Arran Victory. Arran Victory, although second in total yield, gave the largest proportion of ware tubers of the varieties grown; when cooked, all traces of blue coloration vanishes, and it was placed first in the cooking tests for flavour, texture and colour. The flavour of Arran Consul, when boiled, is stated to be similar to that of Kerr's Pink, but it is lacking slightly in colour and texture. In the cooking test Field-Marshal, a late, non-immune variety, was yellow in colour, although excellent in flavour and texture, while the colour and flavour of Ben Cruachan were moderately good, but in texture it compared poorly with all but Majestic, which, when cooked, gave very poor results, being the only one to begin to go black while it cooled.

Fatal Accident to a Belgian Nurseryman.—M. Ernest Haumont, Director of the well-known nursery establishments of M. Eugène Draps, at Uccle, near Brussels, was killed recently by being crushed by the back wheel of a lorry. The road was slippery and the lorry skidded, with the sad result that M. Haumont, as stated above, was caught by the wheel before he could get away. He was taken to the St. Jean Hospital, and was thought to be on the way to recovery, but an operation had to be performed, and he passed away. The deceased, who was fifty-eight years of age, was a valued employee, and had been successively in the service of the firms of Linden, Pauwels and Draps.

R.H.S. Gardens Club Journal.—Students and employees at the R.H.S. Gardens, both past and present, will welcome the appearance of the Club *Journal*, edited by Mr. J. Fraser, F.L.S., V.M.H., for this journal always makes interesting reading. The 1928 issue is not lacking in this respect, and among the articles of especial interest are Mr. G. Fox Wilson's account of the Fourth International Congress of Entomology, held in the United States last year; an interesting description of visits to Dutch nurseries by Mr. K. Therkildsen; an account of the Club's outing to Brighton on July 14 last, by Mr. G. L. Knight; and an original article entitled "Local Weather Forecasting," by G. Edmund Hindley. In such a publication as this the "Extracts from Correspondence" are always of interest, as also are the "Personal" notes. Under "Obituary" the deaths of Frank Reader, and of George Smithers, whom all past Wisleyites will remember, for he was employed at Wisley prior to the Royal Horticultural Society taking possession of it and at the time of his death was leading hand in the wild-garden department. The frontispiece is a reproduction of the portrait of the late Mr. Frank Reader, which appeared in *The Gardeners' Chronicle* at the time of his death.

Paris Spring Show.—The Société Nationale d'Horticulture de France is making arrangements for its annual Spring Exhibition, to be held in Paris, on the Cours-la-Reine site, from May 24 to June 2, inclusive. On Saturday, May 25, the annual horticultural Congress will take place in the large hall of the Society in the Rue de Grenelle, beginning at 9.30 a.m. As evidence of the increasing popularity of the Dahlia as a decorative garden plant and as a cut flower, it may be added that the Society is organising a Dahlia Section among the members for the study of methods of cultivation, raising of new varieties, etc. The first meeting of the Section was held on January 24, under the presidency of M. F. Cayeux.

Grants by the Agricultural Development Commission.—The following grants, among others, were recommended by the Advisory Committee on Agricultural Science, at its meeting on January 15, and have since been approved by the Development Commission:—£25 to Mr. W. E. H. Hodson, of Seale-Hayne Agricultural College, for a visit to Holland to study methods of control of pests and diseases of the Narcissus and other bulbs; £30 to Mr. Morley Davies, of Harper Adams Agricultural College, to enable him to attend a meeting of the International Commission of Soil Science at Köningsberg, and to visit the Sugar Beet Station at Kleinwanzleben and Sugar Beet growing areas; and £100 to Dr. E. M. Crowther, of the Rothamsted Experimental Station, to enable him to attend Commissions of the International Society of Soil Science at Budapest and Königsberg, and to visit leading research laboratories dealing with soils and fertilisers in Germany, Austria, Hungary, Czecho-Slovakia and Denmark.

Seeds for Distressed Miners.—Following a joint appeal by Mr. Leonard G. Sutton (Messrs. Sutton and Sons), and Mr. William Cuthbertson (Messrs. Dobbie and Co., Ltd.), some 76,250 packets of seeds have been promised by seedsmen throughout the British Isles for distribution to miners in the distressed areas.

Heath and Grassland Fires.—Owing to the abnormal dryness of the vegetation, there were many outbreaks of fire last week-end; among the places where these occurred being Ashdown Forest, Hayes Common, Chislehurst, Mitcham, Downham Estate, Bromley; Alderstead Heath, Chobham, Headley Heath, Ashtead, Brooklands, and on the Sussex Weald. The most dangerous fire was at Brooklands. On the Sunday afternoon eight different fires were counted on the Sussex hills. Several parts of Ashdown Forest were also ablaze, but these fires burned themselves out without doing much damage, and more than three acres of Hayes Common were burned. A considerable area of Aldershot Heath was burned, and acres of Fir trees and shrubs were destroyed by fire at Hall Barn, Beaconsfield, Lord Burnham's estate. A large area of Chobham Common was ablaze on the Saturday evening, and still alight on the Sunday morning, while a mountain Gorse fire occurred at Hollywell, North Wales, and extended over an area of four square miles.

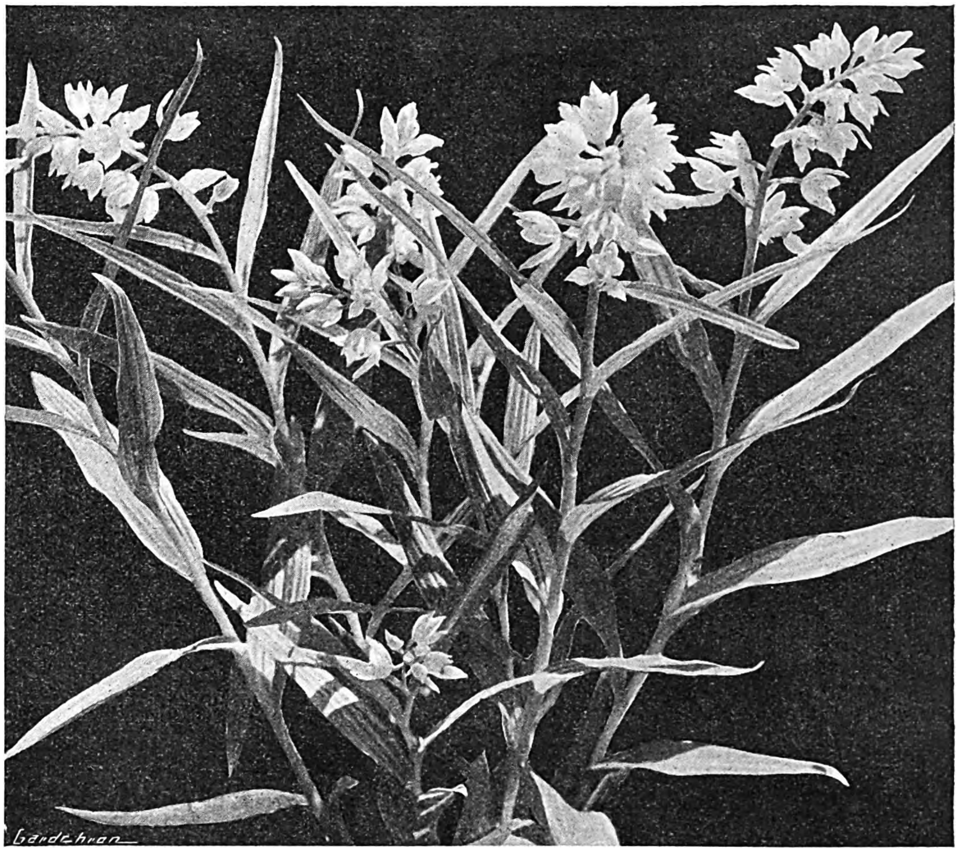


FIG. 95.—LA SELVA: CEPHALANTHERA ENSIFOLIA.
(see p. 205.)

Appointments for the Ensuing Week.—MONDAY, MARCH 18: East Anglian Institute of Agriculture lecture. TUESDAY, MARCH 19: Winchester Horticultural Society's meeting. WEDNESDAY, MARCH 20: Wimbledon and District Gardeners' Society's meeting; Tamar Valley Commercial Show. THURSDAY, MARCH 21: Ipswich Gardeners' Association's meeting; Sundridge and Brasted Horticultural Society's meeting. SATURDAY, MARCH 23: Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Meudon Strawberry.*—My gardener induced me, last November, to let him advertise this valuable fruit in his own name, for the benefit of the school in which he was brought up; but as there is often much charlatanry in use on such occasions, people are chary of giving confidence where pretensions to merit are not well authenticated. I feel strongly the advantage the gardening public would derive from the cultivation of this Strawberry, and herewith beg to give you its history. Meudon, as you know, is one of the Royal Palaces near Paris. Its garden, at the time I speak of it, was occupied by a horticulturist, who gained much celebrity in the *Chronicle* by his successful mode of growing Pineapples in peat. Being curious to witness the fact, I visited Meudon, and found all that had been stated realised. But I at the same time saw what France heretofore did not possess of its own, viz., a splendid looking Strawberry, which was being forced on shelves at the back of the Pine pits. The gardener told me it was one of his own raising, and seeing how abundantly it bore in small six-inch pots, and how beautiful it looked, I induced him to let me have one plant out of the small stock he possessed. I brought it home with me to England, and the stock I now have of what I call the Meudon Strawberry is derived from this single plant. The fruit is as large as that of Keens', but conical and of light red—solid, juicy and sweet, with a quick flavour; excellent for dessert or preserving, and an abundant bearer under all treatments. My gardener has a considerable stock of this Strawberry left for disposal in small quantities, in order to its more general dispersion, as I should be heartily glad to see it become one of the staple plants for general cultivation, and I thus willingly lend the good man my advocacy, accordingly. *Wm. Mason. Necton, Norfolk. Gard. Chron., March* 18, 1854.

Publications Received.—*Einjahrsblumen*, by Paul Kache and Camillo Schneider; Berlin, Westend, Verlag der Gartenschönheit; price-paper, M.9.50; bound, M.12.00.—*Dahlias*, by F. F. Rockwell, pp. 85; The Macmillan Company, New York and London; price 4s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Masdevallias.—The Chimaera section of Masdevallia, that contains such interesting sorts as M. radiosa, M. bella, M. Wallisii, M. Chestertonii, M. Carderi and others, which have been growing at the cool end of the intermediate house during the winter months, generally require some attention at the roots in the early spring. The plants are best grown in Teak-wood baskets, in a compost of three-parts Osmunda fibre and one-part Sphagnum-moss, with charcoal added. This should be made moderately firm among the roots, the rougher parts of the compost being used for drainage (in preference to broken crocks or other hard material) to allow the flower spikes (which are often produced in a downward direction) to pass through without injury. Annual disturbance is not necessary, provided the compost does not become impoverished; if this occurs the plants should be removed from the receptacle and all the old soil and decayed roots removed, replanting them in a basket of suitable size. Water will only be needed in small quantities as the soil becomes dry, until the roots are well established, when an increased quantity may be given. During their active season of growth, these Orchids should not remain dry at the roots for long periods. Maintain a moist and buoyant atmosphere and shade the plants from strong, direct sunshine. During the summer months these Masdevallias may be grown in the cool house, together with the dwarf-growing kinds, which include such interesting forms as M. ionocharis, M. ludibunda, M. simula, M. triaristella, M. tridactylites, M. O'Brieniana, and several other free-flowering sorts, some of which have been in flower most of the winter and will require fresh rooting material as the season advances. These dwarf Masdevallias only require a small quantity of compost to root into, and are best grown in small, well-drained pans, which may be easily suspended from the roof. Stronger-growing sorts, notably M. coccinea and its numerous varieties, and the beautiful, winter-flowering M. tovarensis, are best grown in well-drained pots. Specimens that have lost their leaves in the centre should be broken up and all dead roots and leafless rhizomes removed, each lead being repotted separately, or several arranged together. Keep the base of the plant just below the pot rim and just in contact with the compost, which should be made firm among the roots. Ample room is thus allowed for copious watering during the growing season. An excess of moisture during the winter months will cause the roots of these Orchids to decay and the leaves to fall, but later in the season, during hot weather when the plants are rooting well and growth is active, ample moisture is needed, and occasional light spraying of the foliage is beneficial, air being admitted on all favourable occasions. Thrips should be kept in check by occasionally fumigating the division on quiet evenings, or by spraying the plants at regular intervals on fine, clear days, with a weak solution of an approved insecticide. The flowers of some kinds are easily damaged by nicotine spraying or fumigating, especially M. muscosa and M. tovarensis, which are best removed during this operation, if in bud or flower.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

General Work.—Although the weather has not been favourable, until the last two weeks, fruits in the earliest house have set well; such success is due to keeping the atmospheric conditions right, by maintaining a night temperature of 50° to 55°, with a small amount of air admitted, both night and day, the atmosphere being kept comparatively dry. Pears and Cherries are the most shy setters, especially in cold houses, and both these require a dry atmosphere, kept in motion by the admission of air. The earliest pot trees of Peaches and Nectarines which have been disbudded and the fruits thinned, should have any shoots which are too long shortened or removed as desired; the best fruits are obtained from the boldest flowers near the base of the growths. As a rule, two good growths, one from the base and the terminal one only need be left after disbudding, nearly all the intermediate shoots being removed in due course. Top-dressing is a very important matter, as it is practically impossible for trees growing in a cubic foot of soil to mature a crop of fruits without being top-dressed and fed with liquid manure. The top-dressing material should be prepared in advance and afforded in small quantities frequently from the time the fruits set until they attain full size. Feeding with weak liquid manure is most useful when the stoning period is reached. Late trees comprising a mixed collection, will now present an interesting appearance, especially where flower buds are plentiful and dropping has not marred the prospect of a good crop of fruits. Pears, Plums and Cherries will not withstand hard forcing, therefore the house must be ventilated liberally day and night, ripening of the fruits under the influence of summer heat being the most important consideration. A temperature ranging at about 45° at night, and 55° to 60° by day, and plenty of air admitted, should ensure the free setting of fruits of these subjects without the aid of fire-heat, but always bear in mind the fact that a damp, stagnant atmosphere when these trees are in flower is quite as injurious to them as frost: therefore, fire-heat should be at command to ensure a brisk, buoyant temperature. Trees must be watered regularly every morning, but, as the season advances, this operation may be performed after the house is closed for the day. The trees may be syringed lightly until they come into flower, but when this stage is reached a dry atmosphere and a low temperature should be maintained at night, but a fairly brisk heat during the day, with a free circulation of air, is favourable to fertilisation. Daily distribution of the pollen with a rabbit's tail will aid the process and when the fruits are set syringing and early closing of the house should be practised. Having in my previous notes drawn attention to the damage that may be done by green fly, it is hardly necessary to state that the house should be well fumigated before the trees come into flower.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Bedding Plants in Frames.—Sweet Peas, Pentstemons, etc., that have been wintered in cold frames, should have abundant air on every possible occasion. The lights should be removed entirely during the day, if bright, dry conditions prevail.

The Rock Garden.—Owing to the prolonged period of hard frost, the majority of plants in the rock garden are still dormant, except in the milder districts. Whenever weather conditions permit the rock garden should be attended to, removing decayed leaves that have gathered in the recesses, and which, if left, act as a harbour for slugs, and soon set up decay in plants when wet weather prevails. Attention should also be given to recently planted rock plants. It is well-known that frost has a tendency to lift newly-planted subjects partially out of the soil. Therefore, with the return of more genial conditions, all should be gone over and made firm; if the existing soil is wet and sticky, it will be beneficial to surround the plants with a compost of dry material, such as old potting soil, before firming them. The annual top-dressing of established groups of alpine plants has been delayed; this matter should be attended to so soon as possible, for it is an important factor in the welfare of many of our choice alpines. For the majority, a mixture of good loam and leaf-soil, with an abundance of grit added, will be found suitable, but special mixtures for those requiring peat or lime should be prepared.

Early-flowering Chrysanthemums.—Continue the propagation of these useful plants. Cuttings will root freely at this season, with very little bottom heat. When rooted and potted into three-inch pots, they should be left for a week in a house or pit with a medium temperature until they become established, after which they should have the protection of a cold frame until the weather becomes more genial, when they may be placed in a sheltered corner in the open, preparatory to planting them out. No plants give a better display than do the early-flowering Chrysanthemums where large beds have to be furnished in the autumn; furthermore, they may be grown in the reserve garden or nursery during the summer, and lifted and planted in the flower garden when their flower buds are opening, without showing signs of distress. Where this plan is adopted, it is well to incorporate a plentiful supply of humus as a rooting medium; leaf-soil or decomposed vegetable matter will do, but I have found nothing to compare with spent Hops for getting that close ball of fibrous roots which is so essential if the transplanting of fully developed plants is to be carried out.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

The Fig.—Fig trees on walls that were left unprotected during the recent frosts have suffered badly, and it may be difficult, as yet, to determine to what extent the younger shoots have been injured. Shoots that are badly crippled should be cut out entirely, if they may be spared, otherwise the damaged points should be shortened to an uninjured bud. The embryo fruits can now be seen, and the pruning must be regulated so as to preserve so many of these as possible. The training, of which the fan system is best, allows a space of six inches between each shoot, and this will permit the young growths to be laid in later where necessary. Crowding is fatal to success, as it prevents the sun and air entering freely, which is necessary to ripen the wood. Trained Fig trees that have been making too much growth, at the expense of crop, should be root-pruned. The distance from the base of the tree for the opening of the trench must be governed somewhat by the age of the tree. This trench should be made deep enough to get below the root-system, and all roots should be severed by clean knife cuts sloping from the undersides upwards. When the roots have been cut, the trench should be refilled with a mixture of good turfy loam, and a liberal allowance of old mortar rubble, broken bricks and wood ashes, and the whole made very firm by ramming. This firming should result in a shorter-jointed top growth and subsequent fruitfulness. Copious supplies of liquid manure, and mulchings may be applied when the fruits are swelling.

Cob Nuts and Filberts.—Filberts may be distinguished from Cob Nuts by the greater length of husk and by the shape of the fruits, which is more or less oblong. Cob Nuts are round, or obtusely ovate, and the husks are generally shorter than the nuts. The varieties Cosford, Pearson's Prolific and Merveille de Bollwiller may be taken as examples, although Kentish Cob (syn. Lambert's Filbert) has husks much longer than the nut. The propagation of these is by seeds and suckers. The latter is the chief method of increase, as suckers with good roots are produced in quantity from the base of established trees. These rooted suckers should be planted three feet apart each way in nursery rows, and allowed to remain there for two years. They should be headed back to two feet from the ground and the frame work of branches built up in much the same manner as with the bush Apple. They may then be planted out in their permanent positions ten to twelve feet apart each way. The Nut family thrives best in well-drained, stony soil on hill-sides where full exposure to sun and air may be enjoyed. Deep, rich soil causes the bushes to make too much wood, which is a sure source of unfruitfulness. Low, flat and damp sites should also be avoided.

Pruning Nut Trees.—March is the best month in which to prune Nut trees, as by this time the female flowers can be seen. They are comparatively inconspicuous, being merely tufts of crimson styles protruding from the buds. The leader growths should be shortened to induce the formation of side-shoots or spurs. The lateral growths are shortened to a female bud or buds, and a sufficient number of catkins should be left throughout for purposes of fertilisation.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN,
Brocket Hall, Hertfordshire.

Gloriosa superba and G. Rothschildiana.—Where a good stock of these so-called Spider Lilies is available, a number of the tubers should be turned out of their receptacles and repotted into the pots in which they are to flower, while those that are to form a succession should be allowed to remain as they are for several weeks and should be kept dry at the roots. The transference of the tubers into fresh compost should be done with extra care, as they are very brittle. Gloriosas require a rich, open compost. Single tubers may be grown in seven-inch pots, or several may be grown in receptacles nine inches in diameter. After potting, care is necessary in watering until growth is active. A moist, warm atmosphere is essential for the cultivation of the Spider Lily and, if grown in light shade, long flower stems will be produced, which is an advantage if the blooms are to be used for table decoration.

Campanula pyramidalis.—This Campanula makes an excellent pot plant for decorative purposes, and may be had in flower over a long season during the summer months, when large flowering plants are none too plentiful. To obtain good plants for next season, the seeds should be sown now in a light, open compost, covering them very lightly and placing them in a warm house. When the seedlings appear the receptacles should be placed on a shelf near the roof-glass, and so soon as the seedlings can be handled they should be pricked off into small boxes, subsequently growing them on under cool conditions in pots, or planted out in the open ground, from which they may be lifted and potted in early autumn.

Clivias.—Plants that have been kept somewhat on the dry side may now be watered more freely and fed liberally with liquid manure to induce the production of good flower spikes. Clivias resent frequent repotting and, when this is necessary, it is best done after the plants have flowered. Unless large specimens are desired, they will be found most useful when grown in as small pots as possible. As a rule, Clivias are grown in the same receptacle for several seasons, therefore, when repotting, it is best to wash all the soil from the roots. Plants in good health produce roots in abundance, and consequently make repotting a rather difficult task. Care is necessary not to damage the fleshy roots, for they are apt to decay when injured, and water must be given sparingly until root action is again proceeding. The plants may be syringed lightly, but not too frequently, otherwise the soil will become saturated. Seedling plants may be potted on if necessary, and choice varieties may be propagated by division.

Aspidistras.—Good specimen Aspidistras may now receive a top-dressing of light, rich soil, to which bone-meal has been added, but before proceeding with this work remove a little of the top soil. Other plants may be divided up, and young, healthy specimens potted on, using a compost of two-parts fibrous loam, one-part leaf-mould, and one-part silver sand; water carefully until growth is active again.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER,
Knowle Gardens, Dunster, Somerset.

Onions.—When the weather is suitable, the ground that was previously prepared for Onions should be forked over and, if in a dry condition, levelled and trampled both ways to make it firm. Some growers firm the soil for Onions with a light roller, but if the ground is of a heavy nature, the surface will get so hard during the summer that it will crack badly if so treated, and it is therefore better to maintain a loose surface, which may be hoed frequently. The Onion seeds should be sown thinly in drills drawn fourteen to sixteen inches apart and about two inches deep. If the seeds are sown thickly the resultant plants will be spindly and weak. Among the many varieties of Onions now on the market, none give more satisfactory results than Ailsa Craig and Bedfordshire Champion, provided they are sown early and treated generously. If the bulbs are properly harvested and are stored in a dry, airy shed, they can be had in good condition well on into April, or even May, of the following year.

Cauliflowers.—If seeds of Cauliflowers were sown in boxes or pots some four weeks ago, the seedlings should now be ready for pricking off into frames or boxes, in a compost of sandy loam. Keep the frames closed for a few days until the young plants obtain a root-hold in their new quarters, and, during sunny weather, shade them during the middle part of the day, when the sun-heat is strongest. Admit air sparingly at first, gradually increasing the supply as the plants become established and active in growth. Plenty of mats should be kept handy in case of night frosts. Cauliflower seedlings are easily ruined with too much water, therefore the compost should be kept rather on the dry side until they become firm of stem and hardened.

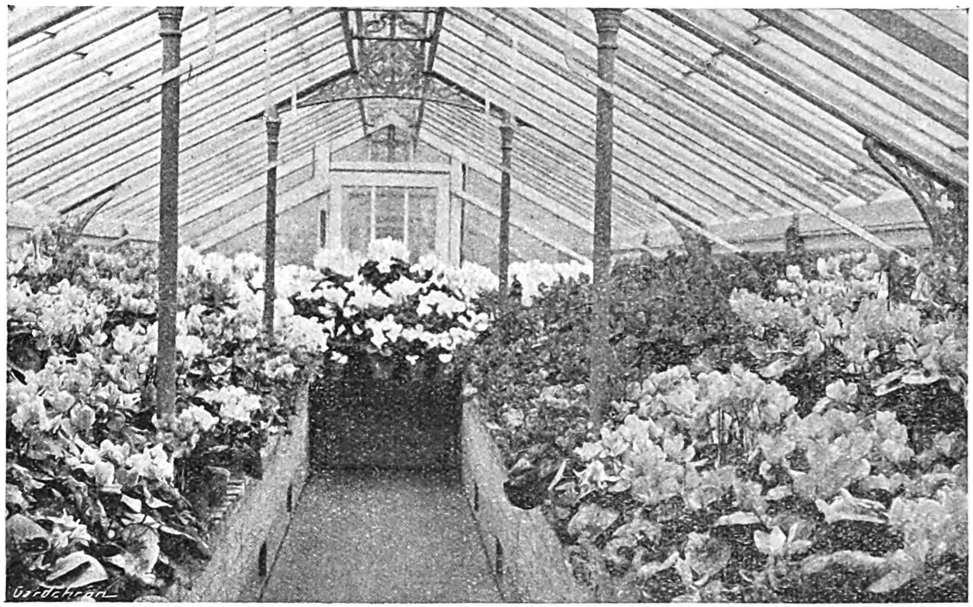

FIG. 96.—HOUSE OF CYCLAMENS AT MORETON PADDOX.
(see p. 201).

Peas.—Another sowing of Peas may be made, preferably of a dwarf variety; The Sherwood and The Laxton are two good sorts for this purpose, but as the abilities of the varieties differ according to the types of soil and conditions, the selection of them must be left to the individual grower's discretion.

Sowing Brassicas.—The ground on a south border should be prepared and sowings made of early and late Cabbage, Savoys, Brussels Sprout, Cauliflower, Scotch Kale, Broccoli, Kohl Rabi, Cos Lettuce and Cabbage Lettuce. When the seeds have been sown and if birds are likely to be troublesome, place a net over the bed.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq.,
Rosemount, Monkton, Ayrshire.

Early Vegetables.—Where a well-sheltered border, with a southern aspect, is available, a small sowing of Early Horn Carrot and Early Milan or another early Turnip should be made. Parsley, Leeks, Brussel Sprouts, Cauliflowers, etc., should be sown to succeed those raised under glass. Salads, such as Lettuce and Radish, may now be sown in the open at intervals of ten days or so. The first sowing or, perhaps, two, of Turnip and Radish may be lost through frost, but it is worth the risk.

Celery Trenches.—No time should be lost in opening the Celery trenches, so that they may be available for hardening-off plants of flowers or vegetables in boxes or pots; the ridges alone provide a great protection, and a few branches or such like placed above will ward off frost.

Strawberries.—The young Strawberry plants in nursery lines do not look very bright at present, but whenever fresh growth shows, they should be planted in their permanent quarters. Fairly heavy soil suits this crop, provided it is well and deeply worked, manured liberally and allowed to consolidate before planting. Whatever method is adopted in planting, the roots should not be doubled up, but spread evenly, working some fine soil among them, afterwards making the soil about them quite firm. The distance at which they are planted must be regulated by the variety, and the soil in which it is grown; some light soils permit of placing the Strawberry plants one foot apart in rows two feet apart, while on strong land thirty inches by fifteen inches apart is quite close enough. As a first early Strawberry, I have found John Ruskin do admirably in many different districts and soils, but only if treated as a yearly crop, mildew being troublesome in the second and succeeding years.

Frost Screens on Walls.—When Apricots and Peaches show signs of opening their flowers, means should be taken to protect them from frost. If proper screens are not available, a double or treble thickness of fruit-netting serves the purpose, and this need not be removed until the fruits have set. Keep the nets clear of the trees by means of a few stakes driven into the ground about a yard or so from the foot of the wall, and secure the nets to prevent damage during wind. Plums and Cherries should also be attended to as they reach the flowering stage, especially those on east and south-east walls.

TREES AND SHRUBS.

HELICHRYSUM SELAGO.

This curious little New Zealand shrub has exceeded all expectations regarding its hardiness, a plant nearly ten years old still flourishing in spite of the recent severe frosts and those of last winter.

H. Selago is a densely twiggy bush of about nine inches in height, the slender branches, with their tiny, close-set leaves, having the appearance of whip-cord plaited in green and silvery-grey. It has occasionally produced a few white flowers, but these are too insignificant to be of any garden value. H. Selago claims a place in the rock garden, both as an interesting curiosity and as a diversion among other dwarf shrubs. It never fails to attract attention, for it is so wholly unlike anything else. The poorest of soil seems to be all it needs, and it appears to be indifferent as to whether it is in sun or shade. My plants have always maintained a neat, well-rounded form, and the oldest of them, whose age is referred to, is not more than one foot across. Propagation is by no means difficult, cuttings striking readily in the later summer. *J.*

UMBELLULARIA CALIFORNICA.

This subject, the Californian Laurel, and for some time known as Oreodaphne californica, is a native of north-west America, where it was found by Douglas and described as forming the greater part of the forests of California and Oregon. There it frequently grows to a height of one hundred feet but, although it is hardy in the south of England, the height attained here rarely exceeds thirty feet. In the younger stages it is slow-growing and forms an excellent evergreen shrub for the back of a sheltered shrubbery. A moist, deep soil is preferred, and it will withstand lenient pruning.

The leaves are alternate, lanceolate, and tapering at both ends; they are highly aromatic and volatile. The scent of the leaves is very like that of camphor, and if it is inhaled heavily it causes sneezing, and I have heard that it produces glandular swellings on the neck, but this can scarcely be credited because, in America, the leaves are used for flavouring soups.

The flowers, which are borne in umbels in April, are yellowish-green, and the fruits are about an inch long, roundish-oval and green, becoming purple. There is a line-drawing illustrating it in Bailey's *Cyclopedia of Horticulture*, and it is also figured in the *Bot. Mag.*, t. 5,320. *H. S. B.*

ALPINE GARDEN.

SOME ALYSSUMS.

A. saxatile is a fine old rock plant, and still among the best in spite of novelties, but the variety A. s. var. citrinum is not less meritorious. This has all the hearty, willing nature of the type, but the luminous, citron-yellow of its blossoms is distinctly its own. I do not know another yellow in the garden which "goes" quite so well with soft lavender-blue as that of this variety, unless it be its namesake among the Hypericums, H. olympicum var. citrinum. The double-flowered form of A. saxatile ought to be a good thing, and doubtless it is under some conditions, but in my hungry soil it does not seem to have enough vigour to make much of a success. The compacta form fails in the same way, but it is just possible that both of these are somewhat eclipsed by the glory of their bigger relations.

A. idaeum is an attractive little plant, small and frail enough for a stone trough or choice place in a dry moraine. Its grey, slender, prostrate shoots, with narrow, pointed, silvery leaves, terminate in clusters of flowers in a clear yellow. This species seems hardy enough, but A. atlanticum suffered severely during recent frosts. The latter is a more compact, semi-prostrate plant with small, spoon-shaped green leaves covered with silvery hairs. Its golden-yellow blossoms make a striking patch of colour on a sunny ledge for many weeks in spring and early summer. A. alpestre is another of these hoary Madworts, its development known as A. serpyllifolium being one of the most pleasing of its many forms. This is also a useful subject for a pig-trough collection of sun- and dry-loving dwarfs. Its tiny leaves are frosted with grey hairs, but the flowers are rather a weak yellow. A. Moellendorfianum, which appears to be a Bosnian form of A. montanum, is silver-scaled in leaf and branch, a loose-habited, trailing plant which seems absolutely immune to wet and frost. Its coronets of pale canary-yellow, over an inch across, make quite an attractive show, and it flowers here more or less all the season.

A. Wulfenianum I once had, and it has not yet been replaced, although many are the base imposters who have arrived proudly bearing its name. This charming plant is a trailer, much after the way of A. idaeum, but it is larger and the leaves are considerably broader and rounder. All parts are silvered and the comparatively big blossoms are a peculiarly brilliant golden-yellow. This is an Alyssum that is worthy of a seat in the stalls of any sunny scree bed of really choice subjects. Most of these plants are lime-lovers, but that element does not appear to be at all essential. They seem to be much more fastidious regarding the sharpness of the drainage, and full exposure to sun is very necessary.

PENTSTEMON CRISTATUS.

That the plant being distributed under this name has a right to its label seems doubtful. It is much like the better-known P. Davidsonii in general appearance, making a squat little bush of hard, angular branches, which are well-furnished with evergreen leaves of a bright and lustrous green, but without so decided a glaucous hue as those of P. Davidsonii. The trumpet-shaped flowers, which are hardly so large as those of the latter, are a brilliant amethyst-crimson, and borne profusely during the later spring and early summer. The plant does not exceed three inches in height, and is quite reasonably hardy. Like the rest of its class, it does best in a stony, rather poor soil, and should have full sun. P. cristatus is reputed to be one of the parents (the other being P. Davidsonii) of the very attractive, P. Six Hills Hybrid. *A. T. J.*

ALCHEMILLA ALPINA.

Of the various alpine plants that are grown for the beauty of their foliage rather than for any floral decorativeness, Alchemilla alpina is one of the most charming, for it forms close masses of leaves, each consisting of from five to seven leaflets which have serrated margins and derive their charm from the silvery, silky covering on their undersides; its flowers, small and greenish, and produced in June, are insignificant. It is one of our native plants, being not uncommon in the Lake District and, to secure the most pleasing effect, should be planted in a warm, sunny position. A. alpina is especially charming when viewed early in the day, when the drops of dew which cling to the ciliated margins of its leaves glisten and sparkle in the morning sun; when so seen, A. alpina has indeed a fairly-like charm. There is a variety major, larger in all its parts and heavier in appearance—a doubtful improvement on the type.

ANEMONE RANUNCULOIDES.

For naturalising in the wild garden or for furnishing the rock garden, this dwarf, small, yellow-flowered Anemone, whose blooms are very suggestive of the Buttercup, may well be employed, for it is free-growing and will brighten the garden early in the spring, its blooms being produced freely during March and April. But on the rock garden it should be planted with care, for when once established it will spread rapidly, after the manner of the Wood Anemone, and will, if planted near them, encroach upon the more aristocratic subjects and rob them of their nourishment, and then, when attempts are made to bring A. ranunculoides within bounds again, much difficulty will be experienced, for it is by no means easy to eradicate, and every tiny tuber left will, perforce, develop into a plant, therefore, in the rock garden, A. ranunculoides should be delegated to a position where it may grow at will without fear of molesting other subjects, there to form a carpet of deeply-toothed leaves, rich green and verdant, and enlightened by solitary blooms, each consisting of five or six elliptical, rich golden-yellow segments. In association with A. ranunculoides, either on the rock garden or in the wild garden, small-flowered bulbous subjects may be planted, its charming effect thereby being increased considerably.

This Anemone is common in sub-alpine regions of Europe and, unlike many of its congeners, it flourishes in chalky soils. *M. W.*

HARDY FLOWER BORDER.

CAMPANULA LATIFOLIA.

Among our native Bellflowers none is so striking as the majestic Campanula latifolia, which, in good soil, will attain a height of at least four feet, and when well-grown is an extremely handsome plant. For C. latifolia is compact and erect in habit and is extremely effective when grown in clumps of three or four plants in the herbaceous border, provided the tall growths, clothed with large, coarsely-toothed leaves, are secured firmly to stakes, for they are rather brittle and liable to be broken off at the base during windy weather. Or C. latifolia may be used for naturalising in the wild garden, a purpose for which it is well adapted as, if anything, it has a preference for partial shade. The flowers of C. latifolia are large, handsome bells, borne in simple, spicate racemes during June and July and rich purplish-blue in colour. This species is one of the easiest to propagate, for it may be divided with ease, and also comes freely from seeds; in fact, when once established in the wild garden it will seed itself about and so reproduce itself freely. For border culture it repays generous treatment, flourishing in rich and deeply-worked soil.

There are several varieties of this noble Campanula, notably var. macrantha, which is even more attractive than the type, although not quite so tall, for its rich, purplish-blue flowers are longer, and in habit it is more compact, its stems and leaves also being slightly downy. The white-flowered form, var. alba, is also an extremely desirable border plant, while var. eriocarpa is less vigorous in growth than the type, and of compact and neat habit, its satiny bells being rich violet-purple. Var. pallida is listed by some nurserymen, its flowers being of a lavender-blue shade. *Kent.*

FLOWER GARDEN.

BIDENS DAHLIOIDES.

For several seasons this charming Composite lived without disturbance in a very dry, sunny border, but it disappeared last winter, probably owing to the frost. Since B. dahlioides comes from Mexico one might expect it to be somewhat tender, mountain plant although it is, and some who are wise take up the tuberous roots and store them like those of Dahlias.

It makes a tuft of deeply-cut leaves, above which the flowering stems rise to the height of a couple of feet. Each of these terminates in summer in a flower, about two inches across, which might be mistaken for the bloom of a Cosmos. In the specimen I had, the broad rays of its blossoms were a pale blush-pink, but I understand that the colour varies to some extent. A meagre soil and a warm situation is what this plant seems to need. Mine, at any rate, did very well with such treatment until too great a faith in the tenderness of the climate lost it for me. *North Wales.*

INDOOR PLANTS.

CYCLAMENS.

IF Cyclamen seeds were sown in September or October last, the young plants should now be in two-and-a-half inch pots, and should be on the shelves near the roof-glass, in a light house, and with a temperature of 45° to 50°. If the shelves have strips of quarter-inch deal wood, two inches deep, screwed on the sides, this will allow for a layer of Cocoa-nut fibre or peat moss, passed through a quarter-inch sieve, on which the small pots may be placed; this will prevent the compost drying out too quickly. There are several methods of growing Cyclamens, and certainly, within the last few years, the culture of Cyclamens has greatly improved, although miserable specimens in five-inch pots are still met with. I remember seeing, at a large show in the midlands, Cyclamen plants which gained first prize, each with about eighteen flowers on stems eighteen inches high, and supported with stakes!

The results I have obtained from the cultural methods I have used for several years have certainly been most satisfactory; for instance, last year, at Moreton Paddox, from seeds sown in September, 1927 (Fig. 96), I had plants that measured five feet in circumference, they were in six-inch pots, each carrying from seventy to one-hundred-and-twenty good, substantial flowers. From the beginning it is very essential that the plants be kept growing in a healthy condition. The compost I use consists of one part good, friable loam, two parts peat-moss put through a quarter-inch sieve, and one part half-decayed Oak or Beech leaves, with a good proportion of charcoal, broken bricks and lime-rubble, and a six-inch potful of Clay's fertiliser to each barrow-load of compost added. I may state that I have always found it a good plan to saturate the peat-moss with liquid manure from the cow-sheds before mixing it with the other ingredients. This compost will be suitable from the time the plants are potted into three-and-a-half-inch pots to the final shifts into five or six-inch or even seven-inch pots. When potting, use clean, well-drained receptacles, taking care to cover the corm lightly; very little ramming is required, in fact, I have always found it best to pack the compost in with the fingers, pressing it very lightly. The final potting should be done in June. I always have a hot-bed prepared in a frame and plunge the pots up to the rims in a falling temperature of 50°. Great care should be taken in watering, syringing and shading. The plants are subject to attacks of green fly, also a yellow thrip which gets into the hearts of the plants; a good method of control is to fumigate the plants once a fortnight with XL All. About the middle of August, the lights of the frames may be left off at night when there is no sign of rain, as Cyclamens relish the heavy dews. Early in September the pots should be lifted nearly, or quite out of the spent hot-bed, also, at this stage, the corms should be cleared of soil to prevent damping. The compost I have advised is a very cheap one, while, if plants have to be sent some distance by road or rail, the weight of this compost compares favourably with the loamy mixture still employed by many growers. *James Page.*

CLUSIA GRANDIFLORA.

THE article on this very beautiful and interesting flowering plant by Mr. L. G. Atkins in your issue of March 2 (p. 158), gave me considerable pleasure. I remember the large specimen he refers to flowering in the stove house at Cambridge Botanic Garden in 1910, and again during June and July, 1911. The charming formation and delicate colouring of the bloom—of such substance it appears as though modelled in wax—appealed to me so much that I endeavoured to portray it in water colours. The effort, although very amateurish in execution, was carried to a determined, if not triumphant, finish, and hangs in my room in this town of mixed memories.

The delicate pink colouring at the base of the otherwise pure white petals, the tight, globular buds partly hidden behind the first expanded flower on each spray, and the massive leaves, dark green above, lighter below—somewhat reminiscent of Ficus elastica in form—with the conspicuous swelling at the base of the petioles, combine to make Clusia grandiflora a remarkably attractive plant for any collection of stove plants where space is not too confined. It may be of some interest to note that during the year 1911 one hundred-and-twelve Natural Orders were represented by plants which flowered in the range of glasshouses at Cambridge Botanic Garden, including the plant under review. *Alfred B. Melles, Ypres, Belgium.*

MEDINILLA MAGNIFICA.

THIS plant is a real aristocrat. Its dignified habit, and the fine colouring of its inflorescence, raises it above the average denizens of our glasshouses, so that one is forced to pay homage to its tropical beauty, even when it is not adorned with blossoms, for its large, leathery, prominently veined leaves are singularly attractive at all times of the year.

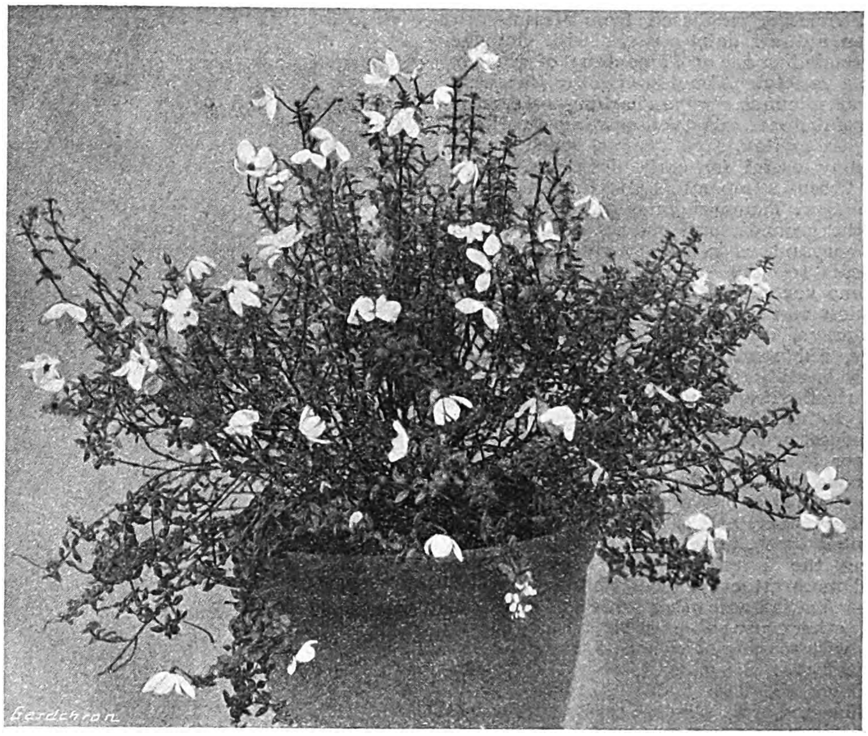

FIG. 97.—TETRATHECA THYMIFOLIA.
(see p. 202).

The inflorescence of this handsome plant is a pendulous, pyramidal panicle, composed of numerous coral-red flowers, against which the deep violet-tinted anthers show up very conspicuously. In addition, the axis and branches of the inflorescence, as well as the bracts, are tinged with pink, so that the whole flower spike exhibits a strikingly beautiful appearance. Unfortunately, this plant is not easy to obtain, although it is cultivated in most botanic gardens.

The usual method of propagating it is by cuttings. These should be selected in March or April, and, after being properly trimmed inserted in small pots of sandy peat, and plunged in a bottom-heated propagator where, in about six weeks, they will have formed an adequate root system and will be ready for potting into four-inch pots. A compost of equal parts of loam and peat, made porous with sufficient silver sand, should be used for potting the plants in all stages of their growth, and it is essential that it should be pressed firmly around the roots, to encourage sturdy growth.

During the summer months the atmosphere must be kept constantly moist by syringing the foliage and damping the floor and stages, and plenty of light should be admitted, so that shading need only be used to protect the plants from the fiercest rays of the sun. To induce the formation of a bushy habit, stopping must be practised in the early stages of growth, but when the desired bushiness is obtained, this practice should be discontinued.

For the final potting it is advisable to mix some well-decayed manure with the compost, and, as it is usual to retain the plants in the same pots (once they have attained the flowering stage) for a number of years, a few lumps of charcoal added will help to maintain its sweetness for a long period.

When the flowers begin to appear in the summer, bi-weekly applications of dilute liquid manure will materially assist in their development, but after the flowers have faded, this practice should be discontinued, or the shoots will become too sappy.

From September until February, it is essential that the plants should be rested in a cooler and drier atmosphere, at the end of which period they should be lightly pruned of straggly shoots, and encouraged into growth by providing them with more warmth and moisture. *G. F. Gardiner, Bristol Botanic Gardens.*

NOTES FROM GLASNEVIN.

FEBRUARY proved a fairly severe month for this locality and was particularly noticeable for violent, cold winds. These were followed by a succession of frosty days when the thermometer registered from 7° to 15° of frost, culminating in a heavy fall of snow. The more tender flowers outside were destroyed. Rhododendron moupinense, which was particularly well-flowered this year, was ruined, although covered every night, and the later flowers on R. dauricum and R. mucronulatum shared a like fate. This check to vegetation may, however, prove a blessing, as other precocious subjects have been retarded. R. Fargesii, well-furnished with buds, was on the point of opening, but became stationary during the severe spell. Within the past few days conditions have become milder, and the red colour of the petals is now showing, still, alas, too early to be safe. One marvels at the hardiness of the old R. Nobleanum, which simply hangs fire while the frost continues and then goes on again.

Recent writers have all commented on the beauty and value of the hardy Heaths, and it is certain that we have no more valuable subjects for display at this season than Erica darleyensis and the many beautiful forms of E. carnea.

Whether planted in generous breadths in a Heath garden, or in clumps about the rock garden, they are invaluable and, fortunately for Glasnevin, they do not object to a little lime, although as a matter of fact we avoid it so far as possible when planting.

Snowdrops, of which we possess a very good collection of species and varieties, all flowered freely in the rock garden, and with one or two exceptions, such as Galanthus Ikariae, are now going over; but in the grass on a north sloping bank the double form is just approaching its best, and has proved more amenable to naturalising than the type, Galanthus nivalis. A colony of Cyclamen coum under a Pine tree is now attracting attention, and we have recently made a considerable planting of C. ibericum acquired from a famous northern Irish garden, where the collections are now being dispersed. Sisyrinchium grandiflorum is now in flower and many other bulbous plants are making rapid progress. Tulipa Kaufmanniana will be in flower, weather permitting, before many days are past, and will be followed by a series lasting into May. One Tulip is already in flower, viz., T. violacea, purchased from Messrs. van Tubergen, a dwarf, dainty species with globular flowers reminding one of T. montana, of which it may be a variety. Also flowering are Narcissus minor var. minimus, always a harbinger of spring, and a useful, dwarf, early, yellow trumpet variety, known here as Rev. Fred Tymins, which proves exceedingly useful for early flowering in the open. Crocus Imperati, C. Imperati var. albida and C. Tommasinianus are all in flower about the grounds, and clumps of C. aureus and C. chrysanthus in variety give colour and brightness to the rock garden. Saxifraga Burseriana var. tridentina is fully open, one of the earliest and best of this section, with pure white flowers, wavy margined and held erect on wiry, red stems. In these early days of spring it is still wise to keep a pane of glass over early Saxifrages if the flowers are to be enjoyed to the fullest extent. Although the alpine house, or frame, is useful in this way, it can never take the place of the rock garden or be more than an adjunct to it. Anemones are now coming into flower; already A. blanda is showing colour, and the Hepatica section is represented by A. angulosa

During the severe weather indoor plants received more attention from visitors, particularly the Acacias and other flowering subjects. Among other species may be noted Acacia aspera, with roughly hairy shoots, hairy, linear-lanceolate leaves, and yellow flower heads borne in pairs from the leaf axils; Acacia diffusa, leaves linear, sharply pointed, scattered, flowers sulphur-yellow in round heads; A. leprosa, a graceful species of open habit, leaves up to two inches long, linear-anceolate, sharply pointed, flower heads yellow; A. Howettii, leaves dark green, one inch long, sharply pointed, flower head pale yellow; and A. ovata, leaves ovate, flowers deep yellow. Better known species are A. dealbata and A. verticillata. A. cyanophylla, with glaucous-green leaves, and A. dodonaeifolia have much larger leaves or phyllodes than many of the other species, and are tree-like in dimensions when allowed to develop. Phylica ericoides, a South African shrub of the Rhamnus family, has narrow, pointed leaves, half-an-inch long, and white beneath, the small, white flowers being borne at the ends of the previous year's shoots. Barosma foetidissima, also from South Africa, is a useful, early-flowering greenhouse shrub with tiny leaves, a quarter-of-an-inch long, the flowers produced at the ends of the shoots, being small, white, with long, protruding anthers. Candollea cuneiformis, an Australian shrub of the Dilleniaceae, is attractive with bright yellow flowers fully an inch across, produced singly at the ends of the shoots; leaves oblanceolate, one-and-a-half inch long by an inch wide. Kunzea oppositifolia, an Australian plant of the Myrtle family, forms a twiggy shrub with minute, scale-like leaves and corymbose heads of pink flowers rendered conspicuous by the numerous stamens characteristic of the family.

Tetratheca thymifolia (Fig. 97) is an uncommon and beautiful dwarf shrub with small, sharply-pointed leaves, the four-petalled flowers fully half-an-inch in diameter, mauve-pink in colour. Eupatorium vernale, acquired from Messrs. Lemoine, of Nancy, bears corymbs of white flower heads and gave promise of being a useful early-flowering greenhouse plant; the cordate-ovate leaves are softly hairy on both surfaces, the stems similarly clothed with hairs. The large genus Cassia exhibits considerable variation in the habit and characters of its species. C. artemisioides is probably little known outside botanic gardens, and would not appeal to any but the collector and lover of plants; the leaflets are linear, greyish-green, differing greatly from those of the commonly-grown C. corymbosa; flowers are produced in the upper leaf axils, and are rich yellow, with dark brown anthers.

An equally polymorphic genus is Euphorbia, usually represented by the Poinsettia, E. pulcherrima, and E. fulgens (jacquiniaeflora). The latter, although attractive as a pot plant when well-grown, only shows what it is capable of when planted out in a warm house or corridor; there it will make long, arching shoots six to eight feet high, well furnished with bright orange flowers from fifteen to eighteen inches from the apex. A more uncommon species is E. punicea, of stouter and stiffer habit, with glaucous-green leaves and flowers distinguished by larger, bright red bracts; this too develops into much finer specimens when planted out. *J. W. Besant.*

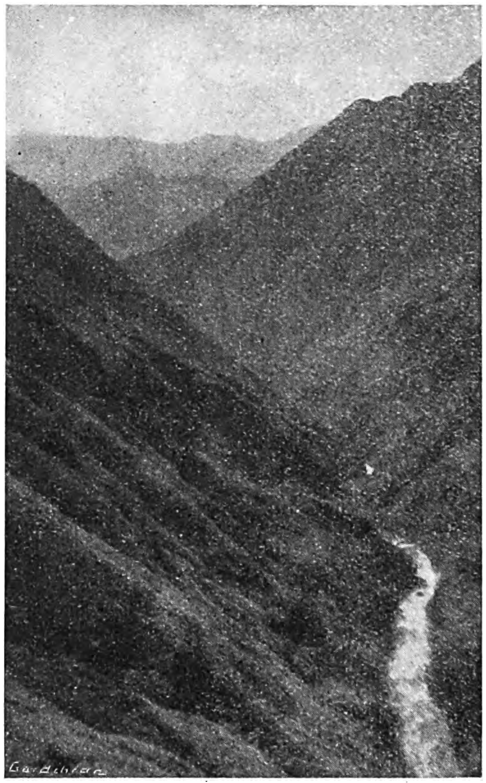

FIG. 98.—THE STEEP-SIDED VALLEY OF THE DELEI.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XVI.—TEMPERATE RAIN FOREST.

THE name "temperate rain forest" may be conveniently given to that belt of forest which lies, roughly, between 5,000 and 7,000 feet throughout the higher ranges of Indo-Himalaya. It is well developed on the southern face of the mountains from Sikkim, in the west, to Yunnan in the east, south of the line of great peaks. It is not an exact term, nor can it be defined in a few words; nevertheless, no botanist will have any difficulty in recognising it when he meets it. Below, it passes into Indo-Malayan sub-tropical forest; above, it passes into Rhododendron-Conifer forest, of which more presently.

The temperate rain forest is usually fairly open, and offers little opposition, other than that of the terrain, to progress in any direction. Even where the undergrowth is chiefly Bamboo, it is scattered, although sometimes thickets of Arundinaria or Phyllostachys are troublesome. The proportion of deciduous trees is fairly high, although the forest gives the impression of being evergreen. Conifers are few and do not grow socially; the same may be stated of Rhododendrons, although these are generally more numerous and varied than Conifers. The temperate rain forest, in fact, may be said to begin at the level at which the first small, tree-Rhododendrons are met with. Climbing plants are few enough to pass almost unnoticed, but epiphytes are legion, and contain a large proportion of Ericaceae. The undergrowth comprises Ferns, Bamboos and Monocotyledons, besides a few shrubs; it develops chiefly during the rainy season (summer). Leaves with drip tips are not uncommon, but that hall-mark of the jungle, the plank buttress-root, hardly survives the passage to a rarer atmosphere. Apparently it is not much wanted, as the trees do not attain any great stature; the largest have massive trunks, there being plenty of room for them to expand. Cauliflory is the exception rather than the rule, but is characteristic of certain genera.

As regards climate, temperate rain forest, as the name suggests, is characteristic of a region of constant precipitation, either in the form of rain or dew. There is no prolonged hot-weather drought as in the typical monsoon region of the plains; consequently the trees do not cast their leaves in the spring. There is, however, a cold weather check in winter, when the deciduous trees shed their leaves. A little snow may fall here, especially towards the upper limits of the forest, but it does not lie. The bulk of the rain falls during the summer (May to October), and is persistent rather than heavy; for weeks the forest is bathed in cloud.

Such, in general, are the features of this forest belt, and if I now mention some of the typical trees, before passing on to a more detailed account of the Delei valley (Fig. 98) in particular, no botanist acquainted with India will have any difficulty in recognising the association to which the above name is applied.

Conifers include Pinus excelsa and species of Podocarpus. Pinus excelsa occurs at much higher elevations in the western Himalayas, but in far northern Burma it is found scattered so low as 6,000 to 7,000 feet, and hardly ascends any higher. Common evergreen trees are Bucklandia populnea, Quercus semiserrata and other species, Castanopsis indica and C. tribuloides, and species of Prunus, Illicium, Michelia, Engelhardtia, Ilex and Rhododendron. Among the last-named are R. arboreum, R. Mackenzianum and R. Nuttallii, which is a big shrub rather than a tree. As one ascends the Rhododendrons rapidly increase in number, in variety and in size, until presently they dominate the forest. Among deciduous trees are the big-leafed Magnolia rostrata and species of Acer, Betula, Corylopsis, Ficus (F. clavata) and Salix. The epiphytic flora includes Orchids, Ericaceae (Rhododendron dendricola, R. vaccinioides and allied species); Pentapterygium, Agapetes, Aeschynanthus species, Begonia species, and small Zingiberaceae.

As already noted, the undergrowth is composed largely of Monocotyledons—Liliaceae, such as Lilium giganteum, Disporum, Paris; Orchidaceae, chiefly species of Phaius; Arisaema; Viola; Oxalis; and small shrubs like Daphne papyracea (cannabina), Mahonia species, Rubus, Ribes, and so forth. Climbing plants are not very noticeable, but include species of Clematis, Lonicera (L. torniflora, etc.), Aristolochia, Sabia and Schizandra.

The temperate rain forest of the Delei valley

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; and March 2, 1929.

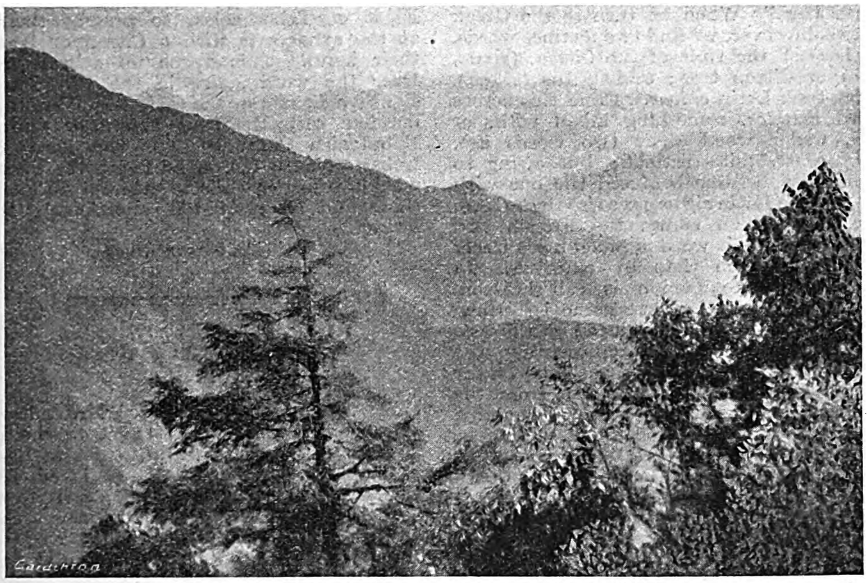

FIG. 99.—THE MISHMI HILLS; TSUGA AND OAK FOREST IN THE FOREGROUND.

was well up to specification. Apparently there are no Pine trees in the Delei, but there was a very handsome Podocarpus, not uncommon between 5,000 and 6,000 feet. The leaves, which are narrow, linear, rather stiff and pointed, reach a length of six inches, and are characterised by two silver stripes on the under surface, one on either side of the prominent midrib, running the whole length of the leaf. Unfortunately, all the trees I saw were males, the pollen being loosed in April. This species is clearly allied to P. neriifolia, which, however, is not found above 3,000 feet in Sikkim.

Corylopsis himalayana was unpleating its fan-shaped leaves in April—it had already shaken out its long catkins, and the delicious fresh green of the leaves reminded me of spring in England. A large Oak was common in this part of the forest; it had huge, serrated leaves of a beautiful grey-blue beneath, and appeared to be leafless, or nearly so, for a short time before the leaf buds broke in May.

Among Rhododendrons, besides those referred to in the last chapter, R. Nuttallii, although local, was common on one ridge, and was just in flower on April 18. Possibly, according to the minute analytical methods current to-day, whereby species are indefinitely multiplied, this would not pass as R. Nuttallii; but that is what I should call it.

One of the most characteristic deciduous trees of the temperate rain forest is Magnolia rostrata, a fine tree with very large, handsome leaves (Fig. 100), but a bitter disappointment in flower. It was not exactly common in the Delei valley, but one could hardly climb to 7,000 feet without coming across at least one specimen, probably half-a-dozen. The tree is easily recognised by its size, being sometimes a hundred feet high, and by its pale, ash-white bark; also by the size of the great leaves lying beneath it, and by its cones, some of which are pretty certain to be picked up under it—which is more than can be said for most species of Magnolia in these forests—I am referring, of course, to the previous year's cones, not to those of the current year. The leaf-buds were still tightly closed on April 15; three weeks later the tree was in full foliage, and in the last week of May it flowered, without adding much to its reputation.

The Delei forests were unusually rich in species of Calanthe or Phaius, of which I recognised five. Three of these flowered in April, the other two in August. The first of the spring-flowering species had flowers of amethyst-purple, deliciously fragrant; another had the fine outer lobes apple-green, and the lip canary-yellow, and this also was fragrant. These were the two common species, and although they really grew together, it was difficult to say where one or the other would be found. On the whole, perhaps, the yellow one climbed to greater heights, and was the commoner, certainly in some districts. Both were handsome Orchids, particularly 'Amethystina.' The third species, of which I found only one clump, had chocolate-red perianth lobes, and the flowers were not fragrant. It was by no means so striking an object as the other two. Although all these species of Phaius may carry a dozen or more blooms on a spike, it is rare for them to ripen more than two or three seed capsules. Another rather arresting plant was a species of Disporum, with cream, or sometimes purple, flowers, which opened early in April. This grew about four feet high before it stopped; the fruits are black.

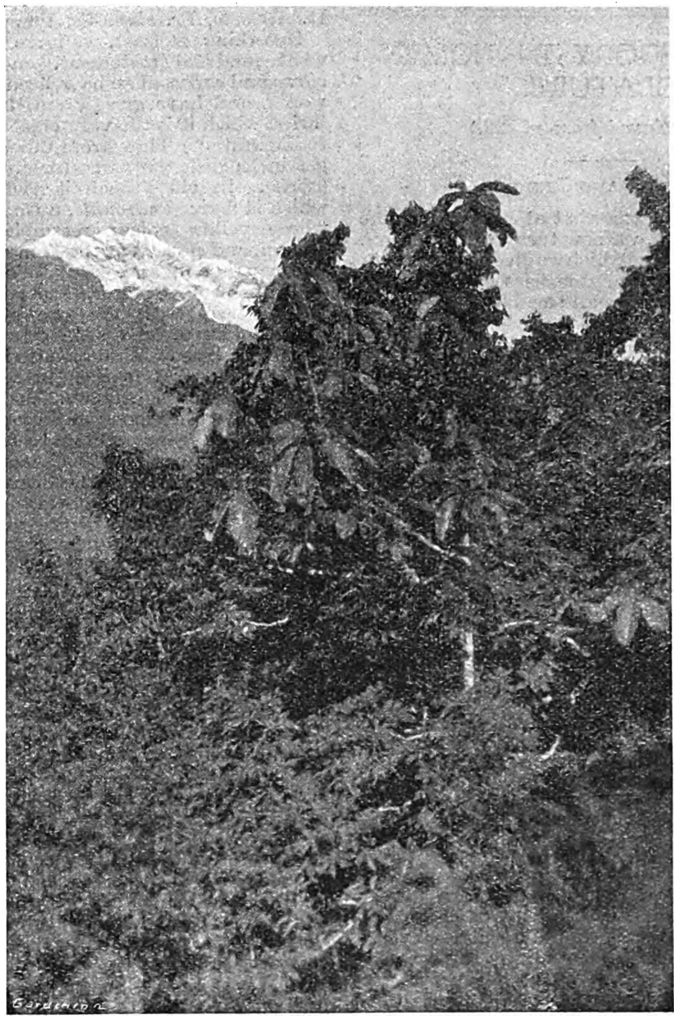

FIG. 100.—THE BIG LEAVES OF MAGNOLIA ROSTRATA.

Of the undershrubs found here, a small, bushy evergreen with prickly stems is worthy of special notice. I hardly know what to call it; at first sight I put it down as an Osmanthus, until I found that it had four stamens. Daphne, my second choice, also seemed to be ruled out. However, if I call it 'Daphmanthus' anyone will be able to form a good idea of its appearance. It flowered in April; the flowers are quite small, and snow-white, but there are plenty of them, and their delicious fragrance recalls that of Daphne. What, however, makes the plant so attractive is the fact that the bright scarlet berries of the previous winter remain on throughout the flowering period; birds apparently let them alone, and not only were the bushes studded with these coral beads in April, but quite a number remained on until August, defying the rain. The flowers were then, of course, long since over, and the new berries, although still green, were ripening slowly; meanwhile, those of the previous year's berries which remained were swollen to twice their normal size, which rendered them highly conspicuous. But it was in April, when the tiny white flowers twinkled like frost among the neat green leaves, lit by rows of scarlet fairy lamps, that the 'Daphmanthus' looked supremely demure. It is a woodland plant, and its hardiness cannot be taken entirely for granted. *F. Kingdon Ward.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

PLANT HISTORY IN NOMENCLATURE.

(*Continued from p.* 122.)

ORANGES AND LEMONS.

HAVING dealt somewhat at length with the word Orange, we now turn to the Lemon. This is the name which we give to the fruit of one of the many different species of Citrus (C. Medica Limonum)—a small tree bearing smooth, Laurel-like leaves. The fruit is not globose or Orange-shaped, but ovate, oval or oblong, terminating at the apex in a small blunt knob, and usually of a lighter yellow colour than the Orange, abounding when well-grown in an acid juice from which lemonade is made. And in this word we see the influence of plants on language. Lemonade is a beverage made from the fruit of the Lemon. But whence comes the name of the fruit itself? Again we have to go to Persia—the land which has given us so many things of value, and such a number of interesting words. We get the word through the French *limon,* which not only gave birth in France to *limonade,* but also to *limonadier,* a coffee-house keeper. Corresponding with the English and French are the Spanish, Portuguese and Italian, which are all traceable to the Arabic *laimun,* or Persian *limun, limuna.* When we remember that the initial letter is liable to change, we shall easily see the same word in the Bengalese *nimbu,* the *nimbuka* of other languages and dialects of India, and so shall understand the Cantonese *ning-mung* (Lemon) and *ning-mung shui,* lemonade, or, literally, Lemon-water.

It is impossible to deal with the subject satisfactorily, however, unless we turn to the scientific term Citrus, with its many and important derivatives. Oranges and Lemons are the fruits of trees which are known botanically under the generic name Citrus. When we have arrived at this fact we suddenly find ourselves in a maze, confronted with all sorts of problems, and liable at any moment, if we do not watch our steps, to trip and stumble and fall. The etymological tangle is at first bewildering from the fact that confusion arose long ago between Citrus and Cedrus. Let us see if, with a little patience, we can bring order out of chaos.

We begin with Citrus, which looks like pure Latin. The dictionaries say that the word is found in Lucretius and elsewhere, and is probably akin to the Greek *κεδσος, cedrus.* From it they derive citreus, " of, or pertaining to the Citrus tree." When we turn to the Greek authorities, however, we find two distinct words, Citron (*κιτσον*) the fruit of the Citrea, (*κιτσια,* or *κιτσεα*), or Citron tree; and Cedrus (*κεδσος*), the Cedar tree, Latin *cedrus.* From this comes the word *cedrotos,* something inlaid with, or made of, Cedar wood. The two words are, then, apparently quite distinct; but owing to their similarity became confused the one with the other. The Latin *citrus* gave rise to the form *citronem,* from which comes the French and English Citron. This word is much more freely used by the French than by ourselves. In modern French the Lemon is called Citron, while what we know by that name is termed *cédrat,* a word which was introduced into France in the sixteenth century, representing the Italian *cedrato.* Note the difference between the two words citron and cedrate, one from the Greek *citron,* the other from *cedrus.* By mixing up the two, endless confusion arose, so that so great an authority as Diez (*Dictionary of the Romance Languages,* s.v. Cedro) was confused thereby. Perhaps I cannot better illustrate what a tangle the words had got into than by giving the definition just as it stands there.

" CEDRO It., Sp. Pg. *cidra,* Pg. also *cidrao,* Fr. Eng. *citron* (fruit); It. *cedro,* Sp. *cidro,* Fr. *citronnier* (tree); from *citrus, citreum.* It. has *cederno* on analogy of *quernus.* The usu. word is the foreign *limone,* q. v. The variable quantity of the L. accounts for the double form in *e* and *i*; hence It. *cedronella,* Sp. *cidronela,* Fr. *citronelle,* balm, L. *citrago*; also It. *citriuolo,* Fr. *citrouille,* Pumpkin."

One thing, at least, we learn from this somewhat muddled statement, and that is that *citrus* and *cedrus* alike have been prolific mother-words, and have greatly enriched our vocabularies, which it is the very object of these papers to illustrate.* Thus, from Citrus or Citron we get in English the name for an invaluable acid (*citric*). In old French it yielded *citre,* from which is derived *citrouille,* a Gourd or Pumpkin, whose yellow colour resembles that of the Lemon, and *citronnier,* the Lemon tree. To these we may add *citrate, citrin, citronnat, citronne,* and others. *Citrino* or *citrina* is defined as an Italian term with the two-fold meaning (1) citron-coloured, and (2) sorte de Mirobolan, the Mirobalano or Mirabolan (as it is indifferently spelt in old dictionaries) being *une espece de prunier.* Thus lightly we skip from Citron to Lemon, from Lemon to Pumpkin, and from Pumpkin to Prune or Plum! How wonderful a plaything is speech and language.

Before we pass from the Citron, let us remark that the fruit has its interesting lore and associations. In the east it may often be found on the altar, and the Chinese give the name Fat-shau or Buddha's hand to a variety which grows into a very monstrous shape. The usual name for the Citron is Heung-ün, or Fragrant Un, probably with reference to its odour and shape.

The derivatives from *cedrus,* which, nevertheless, relate to the Citrus, are many. Diez has already supplied us with a goodly number, such as *cedro* and *cedronella,* but the most important are French. *Cédrat* has already been mentioned. Few things interested me more in Corsica than the Citrus. The Commune of Luri, Cap Corse, is described as " *un immense jardin, ou sont cultives les citronniers et les cédratiers. . . . Le Cap Corse produit par an plus d'un million de kilog de cédrats . . . On fait avec ce fruit, connu vulgairement en Franc sous le nom de poncire de pomme du Paradis ou Pomme d'Adam, des confitures très recherchées; on le confit aussi au sucre par tranches ou en entier.*"

One ought not to leave entirely out of the subject the effect of these fruits on other languages. Germany, in common with the Latin races, has introduced the foregoing terms, and the German dictionary is rich in such words as *limone, citrone, citronenfarben, limonade,* and the like. To go fully into the question in its relation to the Hebrew and other Semitic tongues would require an article by itself. One allusion may, however, be permitted in conclusion. It is a custom among the modern Jews on the day when they celebrate the Feast of Tabernacles, to present themselves at the synagogue with a Citron or Lemon in their hand. This opens up a wide subject. Does the word *hadar* in the Old Testament signify a Lemon or the Citron? Were the Jews familiar with the fruit before or during the Babylonish Captivity? Is the *ethrog* of the Luban coins a Citron or Lemon? Perhaps it would be worth while to attempt an answer to these and other related questions! *Hilderic Friend.*

(*To be continued*).

LA SELVA, NICE.

AT the kind invitation of Mr. Edward H. Woodall, I paid my first visit to the French Riviera to see his beautiful garden at La Selva, Nice. I was told that the time I had chosen—the end of November— was too early to see the garden at its best, but what I saw was quite enough to astonish me. To be removed in a few hours from wintry conditions to a land of brilliant sunshine and tropical vegetation, where plants that we fuss about with in stoves and greenhouses in England, were growing and flowering remarkably in the open, was an amazing experience.

La Selva is situated on high ground, about two miles from Nice, and a beautiful view of the town, with the sea in the distance, is obtained from the terrace. This view was well illustrated in *The Gardeners' Chronicle* for February 4, 1928 (Supplement Plate).

The commodious villa is, for the most part, clothed with beautiful climbing plants, Bougainvilleas being a mass of bloom at the time of my visit. The brightly-coloured trumpets of Bignonia venusta, orange, and B. Cherere (buccinatoria), red, could be seen high up near the roof. Lantanas in several colours, Kennedyas, and the pretty, Heather-like, climbing Lopezia, with dainty, pink flowers borne in the axils of the leaves, were all flowering profusely.

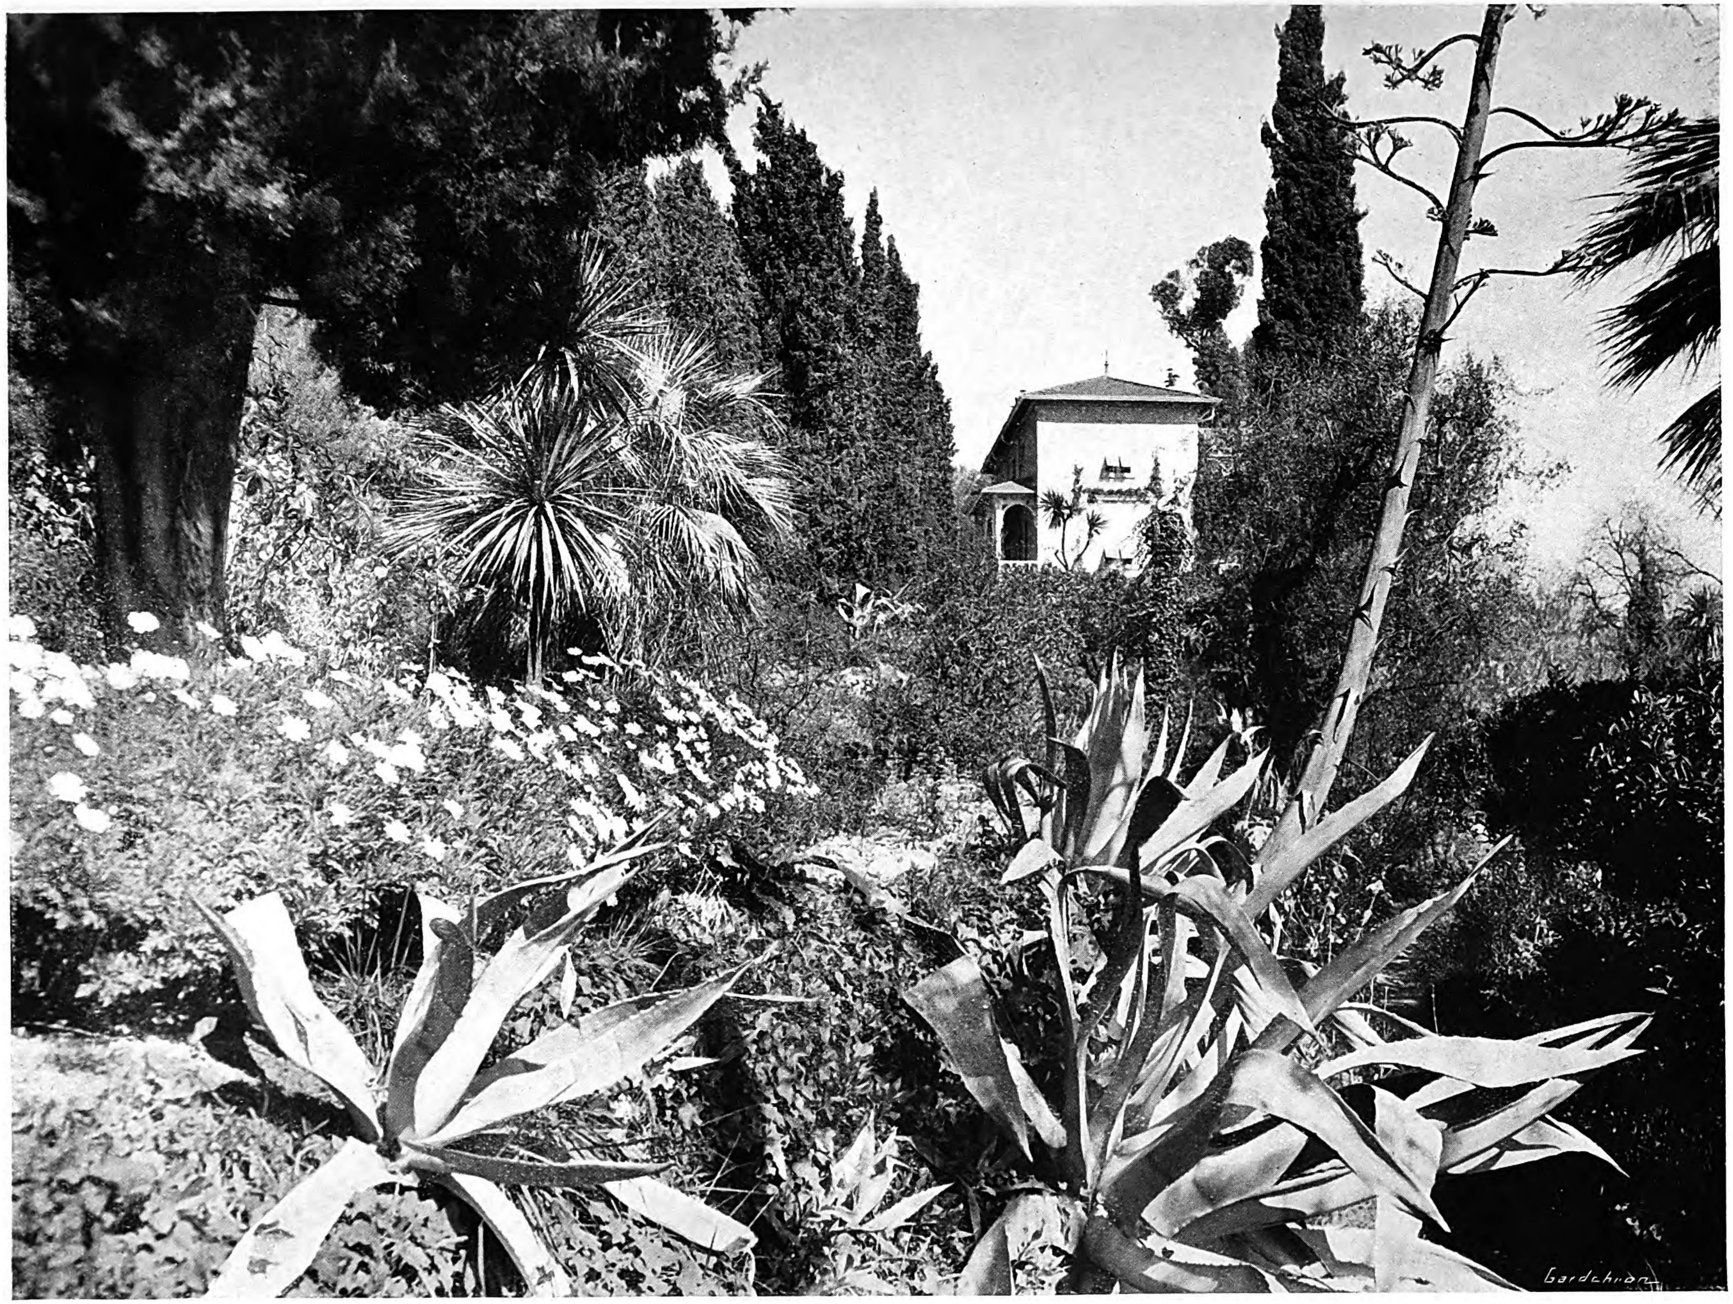
In the large porch at the front door and on the varandah, were groups of flowering plants in pots. Among these I noticed some well-flowered specimens of Cypripedium insigne, and several fine varieties of it. Nerine Mansellii was also flowering freely. All these are grown entirely outside, in the shade of the large Olive trees behind the house, and placed where I saw them when they come into flower.

Opposite the front of the house the ground rises considerably, and has been converted into a rock garden, in which are grown succulents and other subjects that will withstand the dry position and the hot climate (Fig. 101); but alpine gardening as we know it at home is not attempted. Rough stone steps lead to the level ground above where Roses were growing well. The stony, dry-looking soil is not the kind one associates with Roses, but the following varieties were fine:—Hadley, Lady Plymouth, Peace, H. Stevens, La France de '99 and Comtesse de Leusse, and there were great standard specimens of several of these varieties, smothered in bloom. Rambler Roses grew splendidly, many of the varieties in flower being strange to me. An arch of Irene Bennet was particularly striking, the large pink flowers showing up beautifully against the background of blue sky. A little further on were numerous beds of Carnations, of the varieties so popular on the Riviera, in wonderful colours, but the calyces split badly. These are grown to supply cut flowers for the house, and Mr. Woodall informed me that this French strain of Tree-Carnations is much hardier than the more symmetrical type grown in England. Even after weeks of short days and cold nights, bunches of brilliant blooms could be gathered if protected only by mats spread at night over the light wooden frame-work which surrounded every bed.

The greenhouses and the frameyard were

---

* The relationship between Citron and Cedar will be dealt with in my next article.



AGAVES AND BRAHEA ROEZLI AT LA SELVA, NICE.

inspected, and the latter disclosed large batches of Primulas, Cinerarias, Schizanthuses, etc., growing in five-inch pots preparatory to being planted in the beds and borders of the flower garden. These were all growing in the open, with a light frame-work similar to that used for the Carnations, so that protection could be afforded on cold nights. Primula sinensis, P. obconica and P. malacoides are planted out to make a show about Christmas time, followed by Schizanthuses, and the Cinerarias later in March.

Near-by, towering above some shrubs, was the stately Dahlia imperialis, with its pyramidal head of white, Lily-like flowers. It is so striking that one regrets it does not show its beauty under glass at home. I was told that for one whole month this plant is the glory of the garden. Paths winding down the side of the hill lead to a charming valley which, from what I saw and was told, must in the early spring be the great feature of La Selva. Mr. Woodall is fortunate in having this well-wooded, shady valley, and he has made full use of it, growing therein many beautiful subjects that could not be grown so successfully elsewhere. This valley has, very wisely, been kept in a semi-wild state and is, in parts, reminiscent of typical English woodland, but a visitor may be startled to find in such a scene young, self-sown Palms and Agaves springing up through a carpet of Ivy. The common Ivy is a great nuisance in the valley, and much time is spent in keeping it from smothering better things. Ivy seedlings spring up in thousands, and Acanthus mollis is a troublesome weed. Great drifts of Anemones, Orchids (see Fig. 95, p. 197), Narcissi, and species of Cyclamen—that naturalise themselves freely—notably C. libanoticum, and a host of other subjects planted here, must make this valley a very beautiful place in springtime.

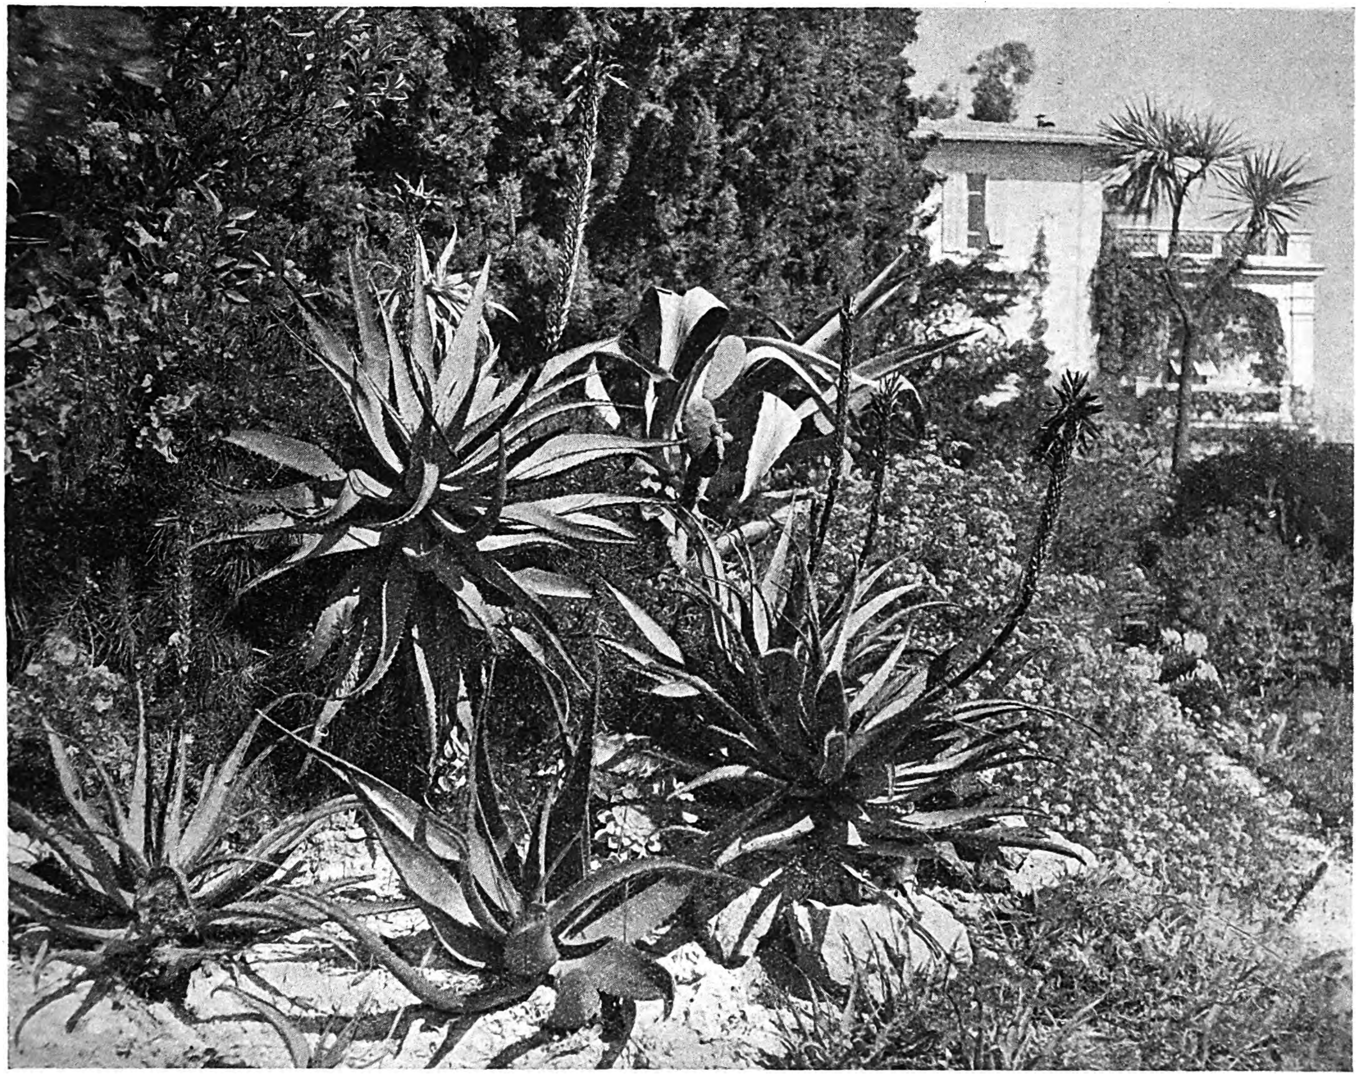


FIG. 101.—LA SELVA: SUCCULENT PLANTS IN THE ROCK GARDEN.

Gardening there is unlike the usual Riviera style, and I could well believe it is particularly interesting to southern gardeners. I was told that a glade planted with Lithospermums, blue Periwinkles and Anemones provides a carpet of blue that attracts many visitors. I noticed in the wide stretch of grass in the bottom of the valley, a perfect specimen of the Italian Cypress, straight and close as though it had been clipped; it must, I think, be quite one hundred feet tall. I understood Mr. Woodall planted this tree himself, and this set me thinking how quickly a garden matures in this favoured land; how splendid to be a tree planter where an average life is not too short to get such results.

On the far side of the valley a beautiful view is obtained of the slope at the top of which the house stands. Tall Olive and Eucalyptus trees grow behind the house, and great Palms and Cypresses stand out in the flower garden, all assisting to make a perfect picture, and one realises, from this view-point, with what foresight and how well and ably the planting has been done, and how the garden has rewarded the owner for the long life of loving care he has devoted to it. Returning by another path to the well-kept flower garden, I noticed a splendidly-grown plant of Agave Franzosini, with leaves almost white. Another glaucous-leaved subject that much impressed me was an immense plant of the Blue Palm—Brahea Roezlii (see Supplement Plate). Flowering Aloes were throwing up their flower spikes and giving promise of a fine display later. In the flower garden proper, I saw several large groups of an orange-coloured Cosmos called Klondyke. I helped myself liberally to seeds of this, hoping that it would not be too late for northern gardens. Very striking also were masses of a fine pink variety of Phlox Drummondii flowering very freely. Suspended by wires, under a rustic arch, were several big tufts of the curious Tillandsia usneoides—Mr. Woodall very aptly calls it the "Air Plant"—and certainly it had nothing else to grow in, having not a vestige of Sphagnum-moss, or any other rooting material, The dead flower spikes indicated that it had flowered extremely well.

Many other beautiful things, including large clumps of Tree Paeonies (Fig. 102), were noticed in this glorious garden, where no thought that it was winter entered my mind, but I am sorry that the latest news from Mr. Woodall was that exceptionally severe weather was being experienced at La Selva, and that the country, at the time of writing (February) was covered with snow which had fallen two nights in succession, while 4° of frost had been registered. He writes: "We are, of course, covering up as well as we can, and so far have just escaped disaster." Such weather, if it continues, must be calamitous to a garden such as the one I have endeavoured to describe, and it is to be greatly hoped that there will be a speedy change to better conditions. *J. Clark, Scarborough.*

ANNUALS UNDER GLASS IN U.S.A.

Apart from what Mr. T. H. Everett (p. 27) wrote as to the importance of annuals under glass for private gardeners in the United States, I venture to suggest that annuals are of even greater importance to the commercial florist. Indeed, it is the florist who has popularised annuals under glass in America. The first taken in hand was the Sweet Pea, the advent of Blanche Ferry prompting one or two growers to try them under glass in winter. By selection, this variety was made still more early, and eventually Anton Zvolanek introduced a strain of winter-flowering grandiflora Sweet Peas which, by degrees, was bred with the Spencers. At first these early varieties were terribly mixed, but, finally, they were rogued until now we have scores of absolutely fixed sorts, possessing all the colours, and the same giant size as the later, summer-flowering kinds. At the New York show in March, several private gardeners exhibit giant exhibition Sweet Pea flowers regularly, their blooms rivalling any grown out-of-doors in England, save that four-flowered spikes are not obtained so readily. Mr. Frank G. Cuthbertson (son of Mr. William Cuthbertson, of Messrs. Dobbie and Co.), of Messrs. C. C. Morse and Co., and Mr. George W. Kerr, of Messrs. W. Atlee Burpee and Co., have done much in the breeding of early-flowering Sweet Peas. Mr. Kerr will be remembered by many, as he was at one time with Messrs. Dobbie and Co., and later with Messrs. Bakers, of Wolverhampton.

Antirrhinums were taken in hand next, Sutton's Pink or Cottage Maid being grown with success before 1910. The seeds used to be imported, but by degrees growers commenced saving their own seeds under glass, and varieties possessing a winter-flowering character were evolved. To-day there are many sorts specially offered for growing under glass, while not a few growers select their own, so that it is common for the first crop to come into the market in November, from which time onwards blooms are available right through the winter and up to June. Growers around New York are particularly clever at producing early Snapdragons; the New York market invariably has forced flowers before any other. Long-stemmed spikes make up to 10s. and 12s. per dozen. Snapdragons are grown under glass on a tremendous scale, and they are much more profitable than Carnations; many former Carnation specialists now grow Antirrhinums instead.

Mignonette became popular in America as an indoor plant about the same time as the Antirrhinum, and by disbudding, immense spikes over a foot in length are produced, although the smaller, naturally-grown stocks are most profitable. To-day, Goliath and Defiance are among the popular florists' sorts.

The Calendula has come to the front during recent times, the beginning of its popularity being due, I think, to the arrival of Messrs. Dobbie's Orange King on the Californian seed farms. This, without doubt, was the parent of Ball's Calendula, a giant-flowered variety especially suited to glasshouse culture. This is the leading Calendula of to-day in America, and good growers produce blooms four inches across on stems up to two feet high; the pale yellow sorts are not quite so large.

Trachymene (Didiscus) coerulea came into vogue some nine or ten years ago, under the name of Blue Lace Flower. It is largely grown by commercial florists, some devoting whole houses to it. Gypsophila elegans in sown thickly in flats, and is sliced off as soon as it blooms, the first crop coming in about January. Lupinus Hartwegii, Larkspurs, Nemesias, Cornflowers, Centaurea imperialis, Bellis, Chrysanthemum coronarium, Matricaria (sold as Feverfew), Stevia, Pansies, Salpiglossis, Stocks and Statice Suworowi, are other subjects grown on a large scale commercially.

Stevia serrata (Piqueria trinervia) comes into flower about November; and Pansies at Christmas, some blooms of these arriving in New York in January being four inches across, with stems nearly twelve inches long, and they realise 40/- per hundred wholesale. Most of the other subjects mentioned are in season in the early spring, for they all have to be grown under fairly cool conditions and refuse to make any headway during mid-winter.

Asters also are popular subjects for growing under glass and while some growers specialise in the early sorts for flowering in July, others plant the late sorts which, while not flowering much ahead of the outdoor plants, are considerably finer and fetch better prices. The "yellows" and "wilt" diseases are so serious in some districts that it is impossible to grow Asters out-of-doors. "Yellows" is caused by a leaf-hopper which lives on such weeds as Docks and Plantains, and where these exist it is useless to try to grow Asters; under glass, the leaf-hopper may be kept at bay by screening the ventilators.

Another remarkable development is the culture of Delphiniums under glass. Belladonna was the first kind to prove amenable and when seeds became available it soon became a general favourite, and still more so when a dark-coloured form named Bellamosum was introduced. Millions of plants of the Belladonna type are raised from seeds sown in January and planted out-of-doors. The plants flower during the summer, and in the fall the roots are placed in cold frames. About the end of December, or later, they are planted in beds or trenches and grown in a temperature of 50°. Some growers obtain flowers by February, but the main supply appears in April. A few growers plant the giant-flowered hybrids under glass and get them in flower about May, making so much as a dollar a spike wholesale. *T. A. Weston, New Jersey, U.S.A.*

NOTICES OF BOOKS.

Starch in the Service of Plant and Man.

Starch is a material of the greatest importance in the economy of plant life, and the story of how plants manufacture and utilise this substance is very lucidly told in the chapter on "Starch in its Relation to Plant Metabolism" in Messrs. Eynon and Lane's admirable book.[*] Under the influence of sunlight, chlorophyll is capable of effecting an interaction between carbon dioxide and water vapour, both present in the atmosphere, with the liberation of oxygen and the production of formaldehyde, which is then polymerised to a sugar and the latter to starch. Starch formed in this way is sometimes called "transitory starch," since, during the night, when the influence of light is withdrawn, all or part of it is broken down into sugar and transferred to other parts of the plant for purposes of nourishment. While, however, only the chlorophyll-containing plastids, or chloroplasts, appear to be capable of synthesising starch from carbon dioxide and water, the colourless plastids are able to build it up from sugar, and many plants manufacture large quantities of starch in this way for use as a reserve food material.

Chemical science is certainly very much nearer the solution of the difficult problem of the chemical composition of starch than was the case twenty or thirty years ago; but, as knowledge has accumulated concerning this very remarkable substance, it has become evident that the problem is of a much more complex character than was at one time realised. It seems pretty certain that starch contains at least two chemically distinct substances, and probably the small amounts of phosphorous and calcium, always present and formerly regarded as being due to impurities, are essential constituents. Messrs. Eynon and Lane discuss the question very fully.

Many plants form reserves of starch in sufficient amounts to make extraction on a commercial scale economically possible, and man has found the substance as useful as has the plant. Not only is starch employed as a food, but it has many important applications in the paper-making and textile industries and in the manufacture of face powders and other cosmetics. Moreover, the fact that starch may be very readily converted into fermentable sugar is a matter of prime importance, beer, whisky and technical alcohol being all correctly described as starchy products.

Starches derived from different plants are by no means identical. They differ from each other in various ways, especially in the size of their granules. The four main commercial sources are Potatos, Maize, Wheat and Rice. Messrs. Eynon and Lane deal very fully with the technical extraction of starch from these materials, and their book is illustrated with photo-micrographs of these and other varieties of starch. Among other starches dealt with are Cassava starch, the various sorts of Arrowroot, and Sago. The first is obtained from the tuberous roots of Jatropha Manihot (Manihot utilissima) and J. dulcis. It is remarkable that the fresh tubers, especially those of the former species, are poisonous, owing to the presence in them of hydrocyanic acid, which is, however, entirely dissipated by cooking, or by the method adopted for extracting and purifying the starch. Tapioca is made from this starch by partially gelatinising it by the agency of heat.

In the course of their book, Messrs. Eynon and Lane deal with many other aspects of the subject of starch, and the volume should be found a useful work of reference to all those concerned in any way with this most important material. *H. S. R.*

Potatos Immune to Wart Disease.

This volume[*] is the third of a series which deals with the Potato; the two earlier ones treated of the diseases of the tuber and the haulm or green parts, respectively. In this volume, the characters of flower, leaf, tuber and sprout of thirty-two wart immune, and eleven susceptible varieties are displayed on twenty-four coloured plates. Accompanying each plate is a description in English, French and German of each variety, so planned as to emphasise the characteristic features of the variety and thus assist the grower to distinguish it from those most likely to occur as rogues or substitutes in a commercial sample of "seed."

The selection of varieties consists of those most commonly grown in Germany, and with the exception of Duke of York, Royal Kidney and Immune Ashleaf, contains none which are of English origin or grown in the United Kingdom.

One is surprised to find Roode Star described as an immune, for although it was at first so listed at Ormskirk, subsequent trials threw grave doubts on the purity of the stocks sent in and the identity of the variety; the latest investigations of Köhler in Germany have confirmed the diagnosis of susceptibility. The point is not of much practical importance in this country as the variety is not grown here, but abroad it is otherwise. A further point of interest in regard to Roode Star is that a selection of it produced by Heine was claimed to be completely immune in the field; this, too, has been disproved by Köhler, and leaves the important question of the possibility of selecting an immune stock from a non-immune, however slight its susceptibility may be, still unproven.

While the plates—more especially when one has in view the price of the volume—are remarkably good, and delineate the characters of tuber and sprout with very considerable accuracy, one must demur at the manner in which the foliage has been portrayed. Apparently the artist, carried away by a desire for light and shade effects, has in most cases unconsciously produced an all too convincing picture of mosaic infection.

This particular volume is undoubtedly of value to those who may have occasion to handle continental stocks, but it is not so generally useful as the two preceding volumes of Parey's Pocket Atlas Series, viz., Nos. 1 and 2. These two volumes treat most efficiently of diseases common to all varieties and lands; the plates are of a very high order of excellence and convey a pictorial presentation which is as convincing as it is accurate. Every agricultural inspector should be armed with them. *Redcliffe N. Salaman.*

THE GENUS PRIMULA.

(*Continued from p. 186*).

LITTLEDALEI (Balf. f.). Littledale's P. (Rotundifolia.)

A BEAUTIFUL and remarkable species which closely resembles some species of Potentilla in leaf and habit. The thick, elongate, reddish rootstock is clothed with the dried remains of previous seasons' leafage, with curled and contorted stalks. The somewhat fleshy leaves, produced in dense tufts, have rounded, heart-shaped blades with upcurved margins, borne on short, slender, narrowly-winged stalks sheathing at the base, in all about three inches long; margins furnished with sharp, triangular teeth; upper surface pale green, sparsely clothed with sub-viscid, glandular down, underside densely clothed with meal-producing, glandular hairs. Flower stem mealy, about two inches tall, immersed in the foliage and bearing an umbel of about eight yellow, purple or mauve, white-eyed blossoms. Corolla flat, about three-quarters-of-an-inch across, with narrowly egg-shaped lobes, the margins of which are frequently furnished with blunt, regular teeth; tube cylindrical, about five-eighths-of-an-inch long, with a ring in the mouth. Flowers in July and August.

Grows in damp clefts of rocks in dense shade, in central and south-eastern Tibet, at 15,000 to 16,000 feet above sea-level.

Culture: Peat and granite chips, in a cool, shady spot, with protection from damp in winter, is indicated.

LITTONIANA (Forrest). Litton's P. (Muscarioides.)

A very handsome, deciduous, perennial species but difficult to retain as such in some localities. It produces a tuft of sub-erect or flaccid, lance-shaped, rather pointed leaves, tapering to a winged stalk, in all four to eight inches long; margins recurved, coarsely or finely toothed; both surfaces more or less smooth, grey-green. Flower stems one to two feet tall, fairly slender, erect, covered with white meal. Flowers in a dense spike up to five inches long, purple or bright lilac, with a deeper tinted tube, drooping, expanding from the base of the spike upwards. Buds and calyces blood-red. Corolla one-quarter- to half-an-inch across, bell-shaped or broadly funnel-shaped, divided into five lance-shaped or narrowly oval lobes. Introduced in 1908. (*Gard. Chron.*, July 10, 1909, Fig. 6, 7, 8; pp. 14, 15).

Grows in open meadows on the mountains flanking the eastern side of the Lichiang valley, in north-western Yunnan, at 10,000 to 11,000 feet above sea-level, and also in similar situations in south-western Szechuan.

Culture: Rich, moist loam in a sheltered but open spot suits it; it is quite hardy.

LONGIFLORA (All.). Long-flowered P. (Farinosae.)

A rather robust member of the Farinosa section, with a rosette of oblong-egg-shaped, rarely oval, leaves, from one inch to three inches long, pointed or blunt, tapering to a short, broad stalk; margins toothed or sub-entire; both surfaces mealy, underside densely so. Flower stem four to twelve inches tall, erect, bearing a many-flowered umbel of violet blossoms with yellow tubes. Corolla shaped like that of P. farinosa, about three-quarters-of-an-inch across; tube cylindrical, many times longer than the calyx. Flowers in June. (Illustrated in *Journ. Roy. Hort. Soc.*, Vol. XXXIX, 1913).

Grows in damp mountain pastures, extending from the Alps of southern Switzerland, throughout the Carpathians, to the mountains of the Balkan Peninsular and Armenia.

Culture: As for P. farinosa.

LONGIPES (Freyn. et Sintini). Armenian P. (Nivales.)

A beautiful, robust, perennial species with tufts of oblong-elliptic leaves from six to nine inches long, blunt at the tip, gradually tapering to a winged stalk; margins edged with regular, blunt teeth; upper surface more or less smooth, underside coated with yellow meal. Flower stem stout, six to fifteen inches tall, bearing an umbel of purple blossoms on somewhat stout stalks. Corolla about one inch across, with broadly heart-shaped lobes. This species flowers during June and July.

Grows in damp situations on the mountains of north-eastern Asia Minor.

Culture: Good, somewhat heavy loam, in a damp, open spot, but well-drained in winter, are its requirements.

LONGIPETIOLATA (Pax. et K. Hoffm.). Long-stalked P. (Nivales.)

This species produces a tuft of membranous leaves from one-and-a-half inch to three inches long, the outermost having orbicular-oblong, blunt blades on long, slender, winged stalks dilated and sheathing at the base, the innermost leaves with oblong or egg-shaped-oblong, pointed blades on slender stalks; margins toothed; both surfaces slightly mealy when young, becoming quite non-mealy when mature. Flower stem four to five inches tall, bearing an umbel of two to four pale violet or pale blue blossoms on mealy stalks a quarter- to half-an-inch long. Corolla about five-eighths-of-an-inch across, with oblong, blunt lobes; tube cylindrical below, dilated upwards, about half-an-inch long. P. longipetiolata flowers during June. It is not at present in cultivation.

FIG. 102.—LA SELVA: TREE PAEONIES.

(see p. 205.)

The plant grows on the mountains near Tatsienlu, in eastern Tibet, at about 13,500 feet above sea-level.

Culture: Good, rich loam and grit, in an open, damp spot, with protection from wet in winter, is indicated.

LONGISCAPA (Ledb.). Long-stemmed P. (Farinosae.)

This deciduous perennial is a sub-species of the variable P. farinosa. It forms a rosette of smooth, non-mealy leaves, one inch to three inches long, with lance-shaped blades tapering to a winged stalk about equalling the blade in length; margins entire or slightly toothed. Flower stem three to fifteen inches tall, slender or rather stout, bearing a many-flowered, umbel of rose-coloured flowers on slender stalks half- to one inch long. Corolla flat, about three-eighths- to five-eighths-of-an-inch across, with heart-shaped, notched lobes; tube cylindrical, approximately five-eighths-of-an-inch in length.

Grows in damp, open situations, usually in stony or rocky soil, ranging from eastern Russia, through central and northern Asia, to the sub-arctic islands of North America.

Culture: Conditions as advised for P. farinosa should suit it. *A. W. Darnell.*

(*To be continued.*)

HOME CORRESPONDENCE.

Lapagerias.—Having noticed the note by *W. P. W.* on Lapagerias, *The Gardeners' Chronicle*, February 23 (p. 145), in the great corridor at Messrs. J. Veitch and Sons' nursery, Chelsea, I may state that I can recall the wonderful display of blooms mentioned, as I was at the nursery fifty-two years ago. I may add that I have at the present time two fine Lapagerias, one white and one red, at the side of the door in our large conservatory; these cover several yards of the roof, and flower most profusely every year. *N. F. E., Surrey.*

Salix lanata var. Stuartii.—I am glad to have had the correct spelling of the varietal name of the above Willow from Mr. Fred. J. Chittenden (see p. 159). I was afraid it was a waif from the Continent whose history was unknown. For that reason I contented myself with a superficial examination, noting that it was distinct in several particulars from the Scotch plant. Had I known that it was raised in this country I would have given it a more critical examination. I am now satisfied that it is the hybrid S. lanata × lapponum, and in the general appearance rather nearer S. lanata than the other parent. The evidence of this lies in the stout twigs, the broadly-oval leaves, their short, sub-acute points, the copious woolly pubescence of the primordial leaves, and the faintly yellow hairs on the scales of the catkins when the buds have nearly burst. The evidence of S. lapponum lies in a thin pubescence on the mature leaves, their sub-acute points, less prominent secondary veins on the under surface, the less copious grey pubescence of the catkins, except for the faint yellow hue as the buds are just bursting, the copious pubescence on the very short pedicel of this ovary, and on the base and apex of the ovary itself. This pubescence on the pedicel and ovary could only come from S. lapponum, for the ovary of S. lanata is glabrous, and that of the former is white with pubescence in its early stages. The late Rev. E. F. Linton, in his Monograph, described S. lanata × lapponum, from south Aberdeen, as a new hybrid, so it is endemic to Scotland. His plant was more near the S. lapponum parent, and had longer points to some of the leaves. There is no evidence of S. repens in Dr. Stuart's hybrid, for I have specimens of S. lanata × repens, raised artificially by E. F. Linton in his garden at Bournemouth. The leaves of this hybrid have strongly twisted points and the copious silky pubescence, with the straight hairs lying parallel with the surface of the leaf, as in S. repens. I could not find a hair of this in Dr. Stuart's hybrid. This gentleman of Chirnside, it may be remembered, was the raiser of the miniature Viola Violetta. *J. Fraser.*

Lonicera Hedges.—I have not seen a hedge of Lonicera ligustrina var. yunnanensis (now called L. pileata var. yunnanensis), as referred to by Mr. J. Matchett Watson (p. 159), who must be in the forefront in making experiments. Curiously enough, I can find no reference to the plant he mentions in any of my books, although I have Alfred Rehder's *Manual of Cultivated Trees and Shrubs*, a very exhaustive book on the subject, dated 1927. He describes L. pileata and L. yunnanensis, but the former is useless for a hedge, and the latter a species quite distinct from L. pileata var. yunnanensis. I have planted, helped to plant or prune, hedges of Beech, Hornbeam, Hawthorn, Holly, Box, Yew, Ligustrum vulgare, L. v. sempervirens, L. ovalifolium, L. o. folius aureis, Euonymus japonicus in several varieties, Cupressus Lawsoniana, and C. nootkatensis; and have seen or heard of hedges of Lonicera nitida, Berberis Darwinii, B. stenophylla, Salix fragilis, S. Smithiana, S. viminalis, Prunus cerasifera, Populus canescens, and Alnus glutinosa. *J. F.*

Strelitzia Reginae.—Some four or five species of Strelitzia are known, all natives of South Africa, and S. Reginae is the most ornamental, if not the most curious. Apparently it is cultivated in the Canary Islands, for over three weeks ago some spikes of it reached Covent Garden Market, among other flowers from Madeira. Two of the spikes came into my possession, and although the flowers are now drying and shrinking, they still retain their colours in a remarkable degree. The three long, upstanding sepals are orange-coloured. One of the petals is very short and all three are deep blue or violet. The two lower and lateral ones cohere by their contiguous edges, and gradually narrow to the apex; the free edge of each, about the middle, is developed into an acute, deflexed auricle like an arrow, and this has given rise to the name Bird's-tongue Flower. The stamens lie within these long petals, and the style projects beyond them, becoming divided into three stigmas which project about an inch beyond the petals. Evidently this combination of petals, stamens and stigmas constitutes the platform on which the insects or other animals alight for the fertilisation of the flowers. The lower sepal of the uppermost flower seldom, if ever, gets out of the very thick, rigid spathe, and illustrations of the species show this defect. There is additional colour in this remarkable inflorescence besides the orange and blue of the flowers. Two or three inches of the upper part of the stem, and the base and the edges of the spathe are red, while the rest of the stem and spathe are glaucous. The plant is as easy to grow as a Canna in a warm house. *F.*

Partial Sterilisation of Soil.—In answer to various letters, I would like to make the following points perfectly clear. (1) Steam sterilisation under pressure is expensive, but effective, and is used by large commercial growers. The best method is to lay the steam-pipes in the house and sterilise the soil where it lies. If it has to be dug up and carted, as in Mr. Falconer's system (which is similar to the one Messrs. Clibrans have been using for years) the baking method is, to my mind, preferable, as in the steaming method there is the expense of the boiler, and no saving of labour. (2) The baking, if done at a temperature of 210°F. only, does not (*a*) burn the soil, (*b*) kill off the beneficial bacteria (as Mr. Summerfield suggests), or (*c*) cause plant foods to be given off as gas, any more than does the steam method. (3) We have, at the Cheshire School of Agriculture, carefully tried all known methods of sterilisation, including Mr. Falconer's method with steam from our dairy boiler; the Sterilatum; chemicals—formaldehyde and di-chlor-cresol, and the Reaseheath method of baking soil; and from our experiments, the latter method has proved itself to be the best. (4) The brick-built Reaseheath steriliser is an ideal method for the small man. Since my article on the subject (p. 67), giving plans, etc., I have seen some twenty or more of these brick-built structures built and in use. Some, holding only four barrow-loads of soil, were built at a cost of £2 only, others, holding five tons of soil, cost £15. May I thank the hundred or more readers of *The Gardeners' Chronicle* who have written me so helpfully on the subject. *W. E. Shewell-Cooper, Cheshire School of Agriculture, Reaseheath, Nantwich.*

——I am writing to express my gratitude to all those who have so kindly contributed to the discussion in *The Gardeners' Chronicle* on "The Partial Sterilisation of Soil." After having attended the growers' conference at Reaseheath, and heard Mr. Shewell-Cooper's eloquent plea in favour of baking, I felt that we here were lagging behind the wheels of progress by relying on the steaming process, which we had practised since Dr. Bewley published his book on *The Diseases of Glasshouse Crops*. The view I have now arrived at, however, may be summed up in the expression often used by a Scotch head gardener under whom I served: "One method is just as good as the other, if not a great deal better"; and after the very valuable contribution to the discussion of Messrs. Falconer and Hamilton, I am quite happy to continue with the steaming process, because, like Mr. Shewell-Cooper, here we are out for the cheapest and most efficient method, and in steaming we believe we have it, because we have had handed over to us for nothing an apparatus that meets our requirements, the fuel consumption of which is a mere detail, wood and small coal answering the purpose admirably. Like Mr. Falconer, my first experience, just thirty years ago, was by baking on a shovel, over the stoke-hole fire, when employed in the Royal Botanic Gardens, Kew, but this was for the raising of Ferns from spores, and, of course, we must take into consideration that Ferns, especially in the earlier stages, belong to a much more primitive type of plant life and possess the pioneer spirit, and can thrive in a much more barren medium than the more highly evolved types of glasshouse plants, fruits and vegetables. Replying to Mr. Shewell-Cooper's recent note (p. 145), it was to the above-mentioned improvised methods, and that portion of the soil resting immediately on the fire-box, to which I alluded in my first note, when I suggested the possibility of loss of plant food. I can see now, however, that if left to the inexperienced and disinterested worker, there are dangers in both methods. The soil we have sterilised by steam this year is quite A.1. as regards texture, and seeds are germinating and growing very satisfactorily, in spite of the very low temperature that has ruled of late. In no case have we had soil turn out like mud. *T. A. Summerfield, The Gardens, Alderley Park, Chelford.*

Erica darleyensis Flowering Late.—In his "Notes from a Welsh Garden," p. 142, Mr. A. T. Johnson describes Erica darleyensis as flowering about six weeks later than usual. I have grown this valuable Heath for between thirty and forty years and have found it to fail to flower in November or early December several times, and when this happened it did not bloom until after D. carnea had come into flower. I have never been able to account for this. This season, my plants of E. darleyensis have just commenced to bloom, while the varieties of E. carnea have been in flower since about the middle of January. *S. Arnott.*

Disease in Chrysanthemums.—Under the heading of a "New Disease in Chrysanthemums" published in *The Gardeners' Chronicle* of February 23, p. 133, Mr. Hugh MacSkimming, Auchenault Gardens, Helensburgh, is credited with its discovery. The suggestion that it might be caused by lack of potash by the East of Scotland College, is wide of the mark, as Mr. MacSkimming is one of the best growers, and believes in using plenty of potash in growing his Chrysanthemums. As time goes on the crop of new diseases seems to keep pace with the improvement and advancement of the Chrysanthemum, which is a very serious thing for market growers, and therefore deserves serious consideration. Can it be the case that propagation by division, cuttings, etc., has its limits? Does a variety peter out after a life limited to a number of years, varying in accordance with culture and treatment or constitution? Can stocks be weakened by over-propagation by division and cuttings? It has long puzzled naturalists why some forms of life propagate themselves by division and at the same time have male and female forms. It may be that in nature there is no real lasting propagation by cell division in the case of lower life, or root division (including cuttings, off-sets, runners, etc.) in the vegetable kingdom, but that all life must really hark back to male and female forms and their function for their real and lasting maintenance. In short, propagation by any means other than by seeds is merely a subsidiary functioning depending on male and female forms for its impetus, its maintenance and renewal. If this theory is correct, prolonged propagation, other than by seeds, will tend to deterioration of stock. In that case we may expect to find a much-propagated stock to gradually, or in some cases suddenly, show signs of exhaustion by growing sickly, erratically, or diseased. We may recall the case of the Hollyhock. It is mainly propagated by seeds now, and the dread disease that nearly wiped it out is little heard of, although still existent. Then we have the fruit-growers' complaints of "Strawberry sickness," and how the crops have shrunk until a really good crop is a thing of the past. It is not long ago since an appeal for help by a despairing grower appeared in the columns of *The Gardeners' Chronicle*. Is the solution to be found in raising plants from seeds from selected healthy stocks, not to use old Strawberry land, and to stop propagating from runners entirely, until we have a strong and robust stock? In the case of the Potato, the petering out of certain varieties after the lapse of a few years has been noted by observant growers. Change of seed sets has done much to keep down Potato disease, as growing the same variety year after year on the same ground from the same stock is sure to end in disaster. Is the Chrysanthemum to be the next subject to show signs of sickness and the diseases of exhaustion? It is a question for growers to seriously consider and only when one gets at the real root cause of a disease can anything be done to correct it. Mr. MacSkimming, in his lecture on "Late-flowering Chrysanthemums," reported in the issue of *Gard. Chron.* for March 2 (p. 171), advises the taking of cuttings only from plants that have done well. Plants that have shown any signs of weakening ought to be avoided. If the theory advanced here is correct, any plants showing disease or even irregularity ought to be destroyed, rather than run the risk of propagating disease. More attention ought to be given to the raising of new varieties from seeds obtained from clean, healthy, robust stock, as the use of this golden method of propagation is out of all proportion to the custom of raising stock from cuttings of existing varieties. If more attention were given to seed-raising, it would do something to preserve the balance in nature at least so far as the Chrysanthemum is concerned. *George Murray, Norcott Hill Gardens.*

Eucryphia cordifolia.—I enclose a snapshot (Fig. 103) of a fine example of Eucryphia cordifolia at Castlewellan. The photograph was, unfortunately, taken on a dull day, but the tree was perfectly beautiful and smothered with flowers. This specimen is rather more than less than thirty feet high, and is worth a journey from London to see, when it is in bloom. Is there a finer specimen in the British Isles? February has dealt with us very severely in Co. Down, and I fear that Daffodils will be very late; varieties that are often in flower at the end of January are not showing colour yet (March 2). *V. Slinger, Donard Nursery, Co. Down.*

FOREIGN CORRESPONDENCE.

AUTUMN TINTS IN JAPAN.

THE interesting article on "Autumn Tints at Wisley," in your issue of November 17, 1928, reminded me of a fine clump of Rodgersia aesculifolia which was grown there when I visited Wisley in 1925. The Horse Chestnut-like leaves were then of brilliant hue, there being none of more splendid crimson colouring, among any herbaceous plants I have ever seen. I forget the date on which I saw the plant, but the beautiful Primula Littoniana was in flower on the rockery at the time.

Our tiny island, called Shodoshima (latitude 34·5°), which is situated about seventy miles west of Osaka, is noted in Japan for the autumn tints of its trees and shrubs. Acer rufinerve and A. palmatum, Vitis Coignetiae, Euonymus alatus and Rhus succedanea are the most gorgeous among them. Acer rufinerve is a grand tree, with large, three-lobed leaves and lovely, green-coloured bark, a colouring retained for many years. Its autumn colouring is far more striking than that of A. palmatum. It loves somewhat shady and moist situations and produces seeds copiously, but, unfortunately, the larvae of an insect devours, in our island, many of them every year. The well-known and finest Vine for brilliant scarlet colouring is undoubtedly Vitis Coignetiae, which covers rocks and trees with strong, fast-growing growths, clothed with showy foliage. It is much sought after by the fanciers of so-called Japanese dwarfed trees, while the landscape gardeners use Vitis Coignetiae in Japanese gardens where an antique appearance is required. Euonymus alatus is a spreading shrub with corky-winged branches and yellowish-red fruits, which are lovely after the leaves have fallen, but its dominant feature is its autumn-tinted foliage, for the leaves show the most pleasing scarlet which, in time, turns to purplish-scarlet. It is worthy of more attention. Among many Japanese trees and shrubs, Rhus succedanea is one of the most striking in autumn. This tree has lustrous leaves, tinted in autumn with brightest scarlet; the colouring is not, so far as I am aware, equalled by any other member of the plant world. R. succedanea is native of southern Japan, extending to the Himalayas, from where, for English gardeners, the hardier type might be obtained. Rhus japonica and R. trichocarpa are also fine in their autumn colouring. The gall-nuts on the leaves of the former tree are gathered in quantity annually for the manufacture of tannin or preparations for medicinal purposes.

For its bright yellow effect, Lindera obtusiloba is one of the best. The large, broadly elliptic or ovoid, rounded leaves are usually shallowly three-lobed, but before these appear, the lovely, small, yellow flowers are produced, to be replaced by the small, round, red fruits in autumn. Ginkgo biloba also has fine, yellow autumn tints.

On seeing Ilex serrata in a garden or its native habitat, with abundant red fruits on its branches in winter, one easliy believes that this species is one of the handsomest fruiting shrubs. Celastrus articulatus is a high-climbing shrub common in Japan. In the autumn, the capsules dehisce widely into three lobes, whose pleasing orange-yellow colour, contrasting with the crimson seeds, makes, after the leaves have fallen, a lovely feature. Ilex latifolia is much prized in Japanese gardens for its large, thick, dark green, oval to oblong-lanceolate leaves; it is one of the best of the genus, and produces beautiful red fruits freely, these remaining until spring.

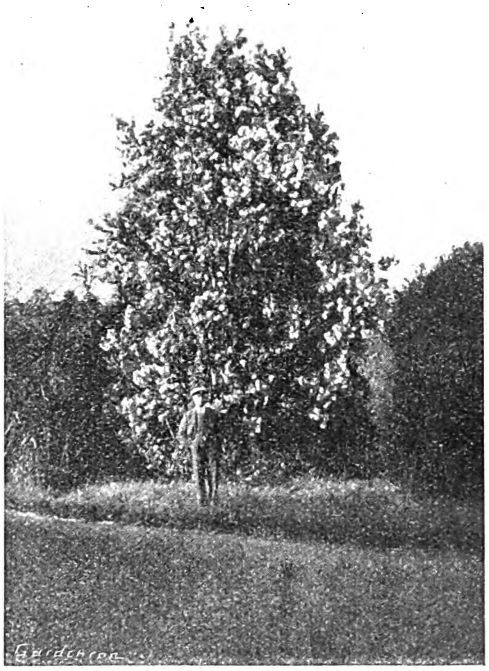

FIG. 103.—EUCRYPHIA CORDIFOLIA AT CASTLEWELLAN.

Nandina domestica is much planted in the gardens everywhere in Japan, for this graceful evergreen Berberidaceous shrub bears handsome, brilliant scarlet berries in clusters terminating the stems, which attain ten feet in height. The leaves of some forms of N. domestica turn rich scarlet in autumn.

On the mountains, I saw a few flowers on several Rhododendron lagopus, which is a very variable species. Some winter-flowering forms of Camellia japonica and C. Sasangua are fine at this time of the year—the end of December—while Daphne odora, Chimonanthus fragrans, Prunus Mume, and its horticultural forms, are commencing to flower. The white, fragrant flowers of Eriobotrya japonica are now being produced freely. *K. Yashiroda, Japan.*

FROST INJURY TO APPLE TREES.

DURING the recent very severe frosty weather which has been experienced at Long Ashton, some very serious cases of frost injury to Apple trees occurred on one of the experimental plots in the Research Station plantations. The injuries were first noted on February 26, but, as the trees had not been examined during the few days previous, it is probable that the injuries had been largely developed a few days before this date.

As the authorities of this Station are unaware of any cases of frost injury to fruit trees, other than damage to blossoms and foliage from spring frosts, having been previously recorded in this country, it seems important to place the present case on record without delay, since, if it proves to be an isolated one, it requires mention, and if other cases have been recorded it seems desirable that the data from so many cases as possible should be collected. Moreover, since the majority of growers are liable to be unacquainted with the nature of the various types of frost injury which may occur, it seems necessary to draw attention to some of these at once, and to the remedial measures usually adopted in such cases.

The writer hopes that growers who have noted any cases of damage will communicate particulars to him in order that a record may be compiled at this Station.

PARTICULARS OF INJURY AT LONG ASHTON.

The cases at Long Ashton on which damage has been observed are as follow:—

(a) A block of forty trees, variety Lane's Prince Albert, of which fifteen show serious damage and three slight damage.

(b) Three trees, variety Lane's Prince Albert, of a number interplanted among other Apple varieties on the same plot as the block in (a). The damage is serious in all three cases.

(c) One tree, variety Early Victoria, growing near the trees in (b); damage is medium and has developed from old growth cracks on the trunk.

(d) Three trees, variety Lane's Prince Albert, of a block of eighty-eight trees of this variety, growing on a plot adjoining the above. In two cases the damage is very slight, and in the other it is medium.

It will be seen from the above that the damage is practically confined to the variety Lane's Prince Albert. In all cases the trees are of comparable age, having been planted in the fall of 1919. Since the most serious case is that of the trees in (a), the particulars of this case are given in detail below.

It is also of interest that fruits of Lane's Prince Albert stored in a common store along with Bramley's Seedling, Allington Pippin, Bismarck and Newton Wonder, in a storage experiment, were badly frozen during the period February 11 to February 20, whereas the other varieties were not affected. King Edward VII was also affected, although not so severely as Lane's Prince Albert.

The character of the damage to the trees in all cases is similar, and is illustrated in the accompanying photograph (Fig. 104), in which one of the most serious cases is shown. The type of injury is that known in America as "bark-splitting."

With two or three exceptions, the main trunk is the affected portion, having split longitudinally, in all cases the injury commencing at a point immediately below the crotch region and developing downwards. In the worst cases the split is about twenty inches long, the width at the widest point being about five-eighths-of-an-inch, and the bark tissues have separated completely, leaving the bare wood exposed. Moreover, along the edges of the splits, in many cases, the bark has separated from the wood in a lateral direction for a distance of approximately one inch. In one or two cases the damage is in the crotch region, and in one it is on the basal portion of a main branch.

The location of the injury in all cases is on the south or south-west side of the tree, with one exception, where it is on the west side.

The site on which the forty trees are located is practically level, and it is significant that the trees comprise the south-west corner block of the plot, and that this portion of the plot is "open" to the south and west. The soil is a deep, fine sandy loam, and is conducive to vigorous growth in Apple trees.

The trees were planted in 1919, and are on various strong, layered stocks from the East Malling and Long Ashton selections. Since planting, the trees have been well cared for, and have made excellent growth. Cultivation has been high and, as the trees have been included in a manurial experiment relating to the use of nitrogenous manures in spring and autumn, they have been manured generously, all receiving annual dressings in winter of superphosphate at 3 cwts. per acre and sulphate of potash at 1 cwt. per acre, while one half of the trees have received nitrate of soda at 2 cwts. per acre each March, and the remainder a similar dressing, but in early August. The trees carried a light crop for the first time in 1927, and blossomed heavily and set a heavy crop in 1928, but this, unfortunately, was lost by injury from a post-blossom spray of colloidal sulphur which also caused the trees to shed about fifty per cent. of their foliage. The remainder of the foliage was shed about November 16, when high gales occurred, and much of the foliage was blown off without showing appreciable tinting.

The trees in the other groups cited above did not receive the colloidal sulphur treatment.

It should be mentioned that at Long Ashton, as is general throughout the south-west of England, fruit trees, as a rule, shut down growth comparatively late in the season owing to the mild, wet autumn conditions which usually prevail, ripening of wood thus often being rather poor, while the winters are generally comparatively mild, the lowest ground temperature at Long Ashton usually showing from 15° to 18°F. of frost.

It will thus be seen that the trees have grown under conditions favourable to rapid growth and rather poor wood ripening, although it cannot be said that they have been abnormal in this latter respect for trees in this district. It is important to note these conditions, since they are those which American horticulturists have found to render trees susceptible to frost injury.

A further point which is stressed by American workers as especially conducive to frost injury is *a rapid lowering of the temperature.* Temperature records obtained at Long Ashton during February show this condition to have obtained during the period from Febuary 10 to February 20, while the minimum temperatures "on grass" for that period were exceptionally low for the district.

The following records show these points:

Date.	In the Screen.		Grass.
	Max.	Min.	
1929			
Feb. 10 ...	45°F.	30°F.	25°F.
,, 11 ...	33°	27°	22°
,, 12 ...	28°	18°	18°
,, 13 ...	27°	9°	8°
,, 14 ...	31°	7°	6°
,, 15 ...	27°	12°	8°
,, 16 ...	33°	19°	21°*
,, 17 ...	36°	13°	12°

,, 19 ...	34°	23°	15°
,, 20 ...	40°	26°	23°

Types of Winter Injury; Conditions Conducive to their Development; and Remedial Measures.

The following comprise the more common forms of winter injury occurring on fruit trees:

1. Root and crown injury—portion of root or bark in crown region is killed.
2. Sunscald—causing frost cankers in bark.
3. Crotch injury—bark injury in crotch region may cause cankers as in 2.
4. Bark splitting—bark splits longitudinally and becomes separated from wood.
5. Trunk splitting—bark and wood split (Fig. 104).

All the above injuries almost invariably develop in the first instance on the south or south-west sides of the trees, as in the Long Ashton cases, the reason being that these portions of the trees are subjected to the highest day temperatures and thus the temperature fall at night is greatest and most rapid for these sides.

The conditions recognised as conducive to the development of these injuries are late autumn growth leading to poor ripening; rapid falls to low temperatures and especially in the early part of the dormant season; and development of extremely low temperatures at any time during the winter.

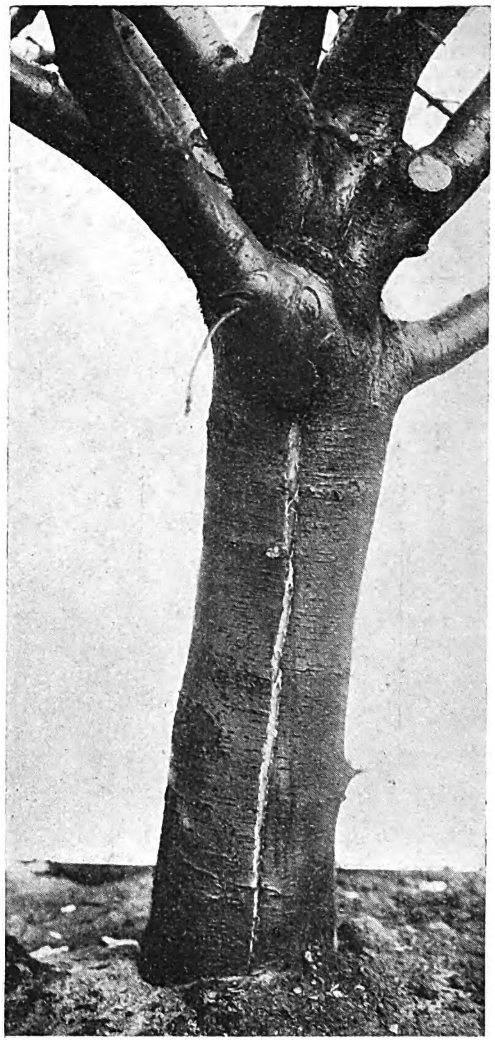

FIG. 104.—A LANE'S PRINCE ALBERT APPLE TREE SPLIT BY FROST.

The remedial measures usually proposed are as follow:—Adapt cultural methods to bring about early ripening of wood, and keep the roots well covered. Where cankers are formed treat these as for ordinary cankers. In cases of bark splitting, tack down the bark so soon as possible and cover with paint, etc., to prevent drying out and infections from organisms. If the bark fails to unite with the wood, cut the loose portion away. Where the trunk is split take measures as for ordinary cases of wood splitting, *e.g.*, binding, bolting, etc.

It may also be necessary in some cases, especially in cases of crown and root injury, to "bridge" the affected portion with long "bridge grafts" or in some cases young stocks are planted on the affected side and "arched" into the scion above the injury. *T. Wallace, Long Ashton Research Station.*

THE NATIONAL IMPORTANCE OF FRUIT-GROWING.—III.

(*Continued from p.* 190).

In the preceding article it was shown that the average Apple crop for England was in the neighbourhood of two tons per acre, and that Mr. Seabrook was one of the very fortunate minority succeeding in producing seven tons per acre, with his two most profitable varieties. His actual crop, however, would appear to be even higher than this, since he states that, unless small Apples will fetch at least £5 a ton, he does not bother to pick them up.

His average price also is more successful than that of many growers. For Bismarck and Worcester Pearmain he gives it at 6s. 2d. a bushel, or about £18 a ton for a seven-year average, including a certain quantity of small Apples, sold at £5 a ton. Owing to the quantity of low-grade Apples marketed, and the absence of standardisation on our markets in the past, it is impossible to give an average price for Apples which would be anything but misleading.

Mr. Seabrook further states that, during the period of sharpest competition with overseas Apples in September and October, his firm was able to obtain a price for Worcester Pearmain 5s. to 10s. a bushel more than that obtained for Californian Gravensteins similarly packed. In this respect he is again fortunate, as the following figures taken from *The Fruit Grower* for 1928 will show:

	Worcester Pearmain.		Gravenstein.
Sept. 13	14/-	...	12/-
,, 20	14/-	...	14/-

Average	14/-	...	13/8

These figures compare Worcester Pearmains and Gravensteins in boxes on the same market at the same date, and show that for similar grades of British and imported Apples there is little difference in price.

It would appear, therefore, that, as the average return for similar samples of British and overseas Apples similarly packed is about the same, the competitive position of the British and overseas grower is determined by the cost of production and marketing. Mr. Seabrook gives the cost of production of a bushel of British Columbian Apples as 4s. 6d., and the freight charges as 4s. 2d. He also states that the journey from Essex to Glasgow, about the longest ever necessary in Britain, costs 1s. 3d. These figures show an advantage of at least 2s. 11d. a bushel on freight charges to the British grower, when the Apples are sold on the same market, and appear, from Mr. Seabrook's paper, to indicate a nett advantage of a similar amount, when neither he nor his overseas competitor is marketing out-of-season fruit. One is, however, tempted to wonder whether the British grower can count on producing his Apples at 4s. 6d. a bushel as can be done in British Columbia.

Mr. Seabrook reckons his costs of production at per acre, and, in his analysis, shows them to be £40 per year after the tenth year. No depreciation is allowed for, since it is assumed that "cost of establishing has been defrayed by interplanted soft fruits." This assumption does not seem to be warranted, mainly because a ten-years-old orchard cannot be said to have no value. He states that, owing to interplanting, and consequent receipts from soft fruits, the orchards show no debt by the time the Apples come into bearing. But neither do they show any profit. If the soft fruits and top fruits had been separately costed, there would, presumably, have been a profit on the former, while the latter would have come into valuation at ten years old at their proper capital value.

Again, Mr. Seabrook includes marketing costs in his figure of £40 per acre for production. These costs must vary with the crop, and Mr. Seabrook's own figures, based, apparently, on a crop of 300 bushels or five tons, show £15 10s. 0d. for carting, packing and carriage, and £2 10s. 0d. for picking. For a crop of two tons the first figure would be reduced to two-fifths, and the second, owing to a rather higher rate for a thinner crop, to about half, bringing them to about £6 4s. 0d., and £1 5s. 0d. respectively. Ignoring costs of picking and marketing, Mr. Seabrook shows a cost of production of £22 an acre, to which should be added depreciation on the lines suggested in the preceding paragraph.

---

* Thermometer under snow.

The cost, then, of picking and marketing is about £3 15s. 0d. a ton, while that of production varies with the crop, being, for five tons an acre, £4 8s. 0d. plus depreciation, and for two tons, £11 0s. 0d., plus depreciation, in each instance taking Mr. Seabrook's figures of cost per acre. The grower who obtains an average crop of two tons an acre is therefore unfortunate in having a far greater cost of production than those who, like Mr. Seabrook, are able to average five to seven tons. *A Norfolk Grower.*

(*To be concluded*).

MARKET FRUIT GARDEN.

The wintry weather of February was experienced to the full in my south-eastern district, except that there was no snow to speak of. Severe frosts occurred night after night, and often held throughout the day as well. More than 20° of frost were registered in the air on several days, and no doubt the thermometer fell still lower on the ground. As a fruit-grower, I have no complaint to make about this exceptional weather. It held vegetation in check, so that now a late flowering period is certain; and this is generally a thing to be desired. Then the frost must have done a great deal of good to the land, a benefit which will be realised when the time comes for cultivation. On days when the surface soil did thaw for a few inches, there was quite a good tilth among bush fruits, almost as if the first hoeing had already been done. Often by this time the soil has become beaten down and hard after the winter's rains. The dryness has, I think, been the greatest blessing of all. Rain fell on only six days during February, the total precipitation being only ·81 inch.

There was, of course, some little difficulty in finding useful work for the men during the cold spell. Pruning was just endurable except on a few days when the wind was too keen. The unskilled hands were able to carry on with the grubbing of trees in an over-crowded plantation, although the ground being frozen to a depth of six inches or more made it rather slow work. The application of manures was also possible. Winter spraying was almost finished before the weather turned cold, and was completed on one or two days when the temperature rose above freezing. A certain amount of planting remains to be done so soon as the ground has thawed. I have never seen the grass in the older orchards so completely browned by frost, helped by the winter spraying. There is scarcely a green blade showing.

Strawberry Troubles.

It seems hardly possible to doubt that the investigators at the Long Ashton Research Station have discovered the chief cause of the widespread trouble with Strawberries in the Strawberry aphis, a pest which has been found in this country only in recent years. This, at any rate, was the conclusion I came to after hearing a lecture on the subject by Mr. Staniland of that station, and seeing the lantern slides with which he illustrated his remarks. The main trouble in most districts is that known as small leaf. In some cases this condition is caused by root injury done by digging too close to the plants, or by crown injury done with the hoe, or even by slugs or leather-jackets; but in such cases the plants may recover in the following season. Water-logging is another cause of small leaf. In the great majority of cases, however, where small leaf is widespread, it is due to Strawberry aphis. Gardeners often conclude that their crops are not suffering from aphis because they cannot find the insects on the plants showing the small leaf symptoms. This is because, by the time these symptoms become prominent, the aphides have exhausted all the sugar in the sap and have left the plants to find fresh quarters on others. They should therefore be looked for on the plants which still appear to be healthy. They are seldom numerous, and will be found only on the youngest leaves at the crown of the plant, since they desert the leaves as they exhaust the sugar and pass on to younger ones. There is no recovery from small leaf caused by aphis. Owing to the absence of sugar the plants do not bear fruits; and they go from bad to worse, the final stage being the dying condition known in some districts as "patch" and hitherto thought to be a separate disease.

Mr. Staniland holds out no hope for Strawberry growers who are not prepared to control the aphis by spraying or dusting. When runners are bought they should be dipped in a solution of half-an-ounce of nicotine (ninety-five per cent. pure) in ten gallons of water with enough soft soap to produce a lather on agitation. This ensures a clean start. But reinfestation by aphides must be expected in all places where Strawberries are grown by neighbouring gardeners. For this reason it is essential to spray or dust the plants each year after the crop has been picked. For year-old plants spraying with the wash already mentioned is the best treatment. Older plants are probably better dusted with a nicotine powder insecticide applied with a proper dusting machine. Spraying or dusting should be done immediately after picking is finished, and should be repeated four or five days later. As an alternative, suitable only for growers in an isolated position where spring reinfestation from neighbouring beds is less likely, winter spraying may be done, while the plants are quite dormant, with tar distillate wash at two per cent. strength. This burns the outer leaves, but does no ultimate harm. Burning off the straw litter over the plants after picking has given a satisfactory control in some cases, but not in others. It is uncertain in its effect owing to the variation in weather conditions when the work is done.

Other familiar troubles among Strawberries are red-plant and Cauliflower disease, both of which are possibly caused by eel-worm. These are nothing like so widespread as small-leaf, and can only be dealt with by rogueing the beds every year and destroying affected plants. Obviously they should never be propagated from. Runners should be bought only from raisers certified by the Ministry of Agriculture as having thoroughly rogued their stocks. Certificates are not granted until inspectors are satisfied that all doubtful plants have been destroyed. Super-certificates are allowed only to those who de-blossom the plants from which they take runners, a practice which produces stronger plants.

Effect of Grass on Fruit Trees.

As I am much interested in grassed orchards, I have been reading again the reports of the old Woburn Experimental Fruit Farm, in which Pickering describes his investigations into the effect of grass over the roots of fruit trees. At Ridgemont, on thin soil over Oxford clay, grass had a most harmful effect on the trees, more so than it has in most places. Growth was almost entirely arrested and the trees became hopelessly stunted. Pickering therefore set himself to find out how the grass brought about this effect. Mainly by means of pot experiments, he satisfied himself that it was not a matter of soil aeration, moisture, temperature, plant food or bacteria. He considered, therefore, that this left only the possibility of the formation by the grass of some material actually toxic to the trees. He had great difficulty in proving this, but in the end claimed that he had done so. First of all he tried watering trees in pots with the leachings from grass grown in sand without manure. So far from the trees objecting to this, some fifty-eight per cent. increase in vigour resulted from the use of the leachings.

In another attempt to find evidence of a toxic substance, soil from under grass and soil from tilled land were compared by germinating seeds in them. Here again the result was in favour of the grass. Pickering considered that these failures indicated that the toxic material must be of a very unstable nature, easily oxidised by exposure to the air and changed into some substance actually beneficial to the trees. The final step was to arrange trays with perforated bottoms over the soil or sand in the pots in which the trees were growing, and to grow grass in sand in these trays. In this way it was hoped that the trees would receive the leachings from the grass without the possibility of oxidation by the air, while the grass would not be able to extract plant food from the soil below the bottoms of the trays. Thus, at last, some evidence of a toxic influence by the grass was obtained, although it was not of a very convincing nature.

Modern Ideas.

I do not know whether the present generation of research workers recognise Pickering's conclusions, but I rather think not. Pickering described the grass effect quite correctly as follows:—Reduced growth and vigour. Smaller leaves and those of light colour and unhealthy appearance. Autumn tints acquired earlier than on tilled land. Light-coloured bark. Small fruit of very high colour. Now these symptoms, thanks to Wallace's famous manurial experiments, are recognised as being simply those of nitrogen starvation. That the grass effect can be overcome by generous manuring has been shown by many growers who have run pigs or poultry under the trees. In some cases, in fact, the trees have been rendered too vigorous by such means. In America the annual application of nitrogenous fertilisers has been found to answer in the same way. This treatment has only recently begun to receive attention in this country, but it has generally proved successful. That there are difficulties in certain conditions I know from my own experience; but I believe it is only a matter of giving enough manure and possibly of finding the best source of nitrogen to suit the soil. If Pickering was right about grass forming a toxic substance, he was certainly right also as to the very unstable nature of that substance, for it is evidently easily overcome. As a matter of fact, he did produce evidence of the grass effect being reduced by feeding, although he made light of it. He found that the effect was much less on some soils than on others. He mentions one case in which the influence was nil, this being where the ground had been cultivated previously for growing vegetables, and was therefore in rich condition. *Market Grower.*

FRUIT REGISTER.

APPLE ADAMS'S PEARMAIN.

This old favourite has completed its century and still figures in any considerable collection on the exhibition table, although it is seldom seen even there at its best—*i.e.*, five or six ounce fruits with a colour like that of the rising sun. The fruit has such a distinctive flavour that anyone familiar with it could recognise it in the dark.

Adams's Pearmain makes a perfect bush, neither too spreading not too upright, and its long, supple shoots feather well if shortened moderately. It comes into bearing fairly early and is a regular cropper, although not unduly heavy. Gathered in late October and stored well, the fruits may be kept in good condition until the end of March. A characteristic of it is its rather narrow, spoon-shaped leaves, while its time of flowering is a little on the early side of mid-season. Nothing is known of its parentage and history, except that it is named after the man who introduced it. *A. Petts.*

SOCIETIES.

ROYAL HORTICULTURAL.

March 12 and 13.—The first two-day show of the year, which was held in the new Horticultural Hall, Westminster, was rather a small one, but the attendance was exceptionally good. Orchids were shown extensively, and while Cymbidiums were especially prominent, there were also very good Cattleyas, Cypripediums, Oncidiums, Dendrobiums and other genera. The Orchid Committee recommended one First Class Certificate and five Awards of Merit to novelties, and three Gold Medals to the very best of the admirable groups. Rock garden exhibits were staged in increased numbers, and these are now becoming very attractive. Forced shrubs, Roses and Carnations were shown in good quality. The Floral Committee recommended four Awards of Merit to novelties. The Narcissus and Tulip Committee met, but had no novelty of moment, although there were several groups of early flowers. The Fruit and Vegetable Committee made sympathetic reference to the loss it, and horticulture generally, has sustained through the death of Mr. Peter C. M. Veitch; there was no novelty of merit, and only a collection of Onions in the hall for consideration.

Orchid Committee.

Present: Mr. Frederick J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Secretary), Colonel Stephenson Clarke, Mr. A. Dye, Mr. H. G. Alexander, Mr. S. Flory, Mr. Charles H. Curtis, Mr. H. H. Smith, Mr. J. E. Shill, Mr. A. McBean, Mr. T. Armstrong, Mr. T. W. Taylor, Mr. Fred K. Sander, Mr. J. Cowan and Mr. S. Low.

First Class Certificates.

Cymbidium Gold Crest (parentage unknown).—A very bold Cymbidium, with substantial flowers of fine form. The sepals and petals are pure white and the lip is also pure white, save for a golden crest and one or two small, rose-purple dots; the column is also rose coloured. Shown by Sir William Cooke, Bart. (gr. Mr. W. Butcher), Wylde Court, Hampstead Norris, Newbury.

Awards of Merit.

Cymbidium Ralph Sander, Old Quarry variety (C. Cooperi × C. I'Ansoni).—A very striking hybrid represented by a plant which carried two spikes and an aggregate of nineteen flowers. The sepals and petals are bronzy, with buff base, and the lip is pale cream, with heavy, red-brown markings. Shown by W. J. Burstow, Esq., Old Quarry, Haywards Heath.

Cymbidium Pipit var. Mandarin (C. Gottianum × C. Miranda).—A very distinct hybrid with buff, pink-shaded sepals and petals, with a few faint purplish lines; lip buff, shading to pale yellow and freely marked with bright yellowish-brown. Shown by Messrs. H. G. Alexander.

Phalaenopsis amabilis var. Elisabethae.—This was shown as a hybrid between P. amabilis and P. Rimestadiana. It is a beautiful Orchid, with large, white flowers of excellent form and substance. Shown by Messrs. Sanders.

Brasso-Laelio-Cattleya Vashti (Laelio-Cattleya Beatrice × B.-C. Bianca).—A glorious Orchid, with very big flowers; the wide and fringed petals are palest pinky-mauve, and the sepals a trifle lighter. The lip is wide, rounded, frilled and of a rich purple colour, with mauve throat and white column. Shown by Messrs. J. and A. McBean.

Laelio-Cattleya Vega (L.-C. Soulange × L.-C. Rubens.).—A hybrid of particularly beautiful form and colour; the petals are of unusual width and of soft rosy-mauve colouring; the sepals are a trifle paler. The wide, shapely and frilled lip is of the richest crimson-purple colour, with yellow and orange in the throat. Shown by Messrs. J. and A. McBean.

Groups.

Robert Paterson, Esq. (gr. Mr. Merry), Stonehurst, Ardingly, put up a very fine group in which all the plants were admirably arranged. Cymbidiums were the leading feature, and of these we were particularly attracted by C. Ceres, C. Miranda var. Golden Oriole, C. Pauwelsii in variety, C. Yellow Hammer, C. Ringdove, C. Curlew, very fine, C. Landrail, C. Gannet and C. Gottianum. Odontoglossums included O. Naomi, O. crispum var. xanthotes, and other varieties, O. Conquest and O. Caroline. Lycastes and Cypripediums were shown capitally, and the latter included C. Maudiae, C. Tom Worsley, the pretty C. Boltonii, and the handsome C. Lord Wolmer var. Plutus. There were many other Orchids in this fine exhibit, notably Miltonia Kennie, M. Beau Brummel, Tetramicra bicolor, Saccolabium bellinum with three spikes of its quaint flowers, Odontioda Bradshawiae, and Laelio-Cattleya Eunice var. alba with seven spikes (Cultural Commendation).

In the bright exhibit made by S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton, there were capital plants of Dendrobium Gatton Monarch, D. atro-violaceum, Odontoglossum Pescatorei, various Cymbidiums, Sophronitis grandiflora, Oncidium Cavendishianum and the old Laelia harpophylla. In Mr. J. Evans' group we noticed the chaste Cattleya Mary Sander with three big blooms, Cypripedium Vashti, Odontoglossum Penelope with two spikes of brilliant flowers, O. Mirum, O. triumphans, Miltonia St. Andre and good Cymbidiums. Cypripedium Pixie, various Cymbidiums, Dendrobiums and Odontoglossums were shown by Mr. H. Dixon.

A bright display of Cymbidiums was staged by Messrs. J. and A. McBean, and they showed handsome spikes of C. Venus, C. Alexanderi in variety, C. Ceres, C. Redstart and C. Carol. Laelio-Cattleya Arcturus—an anceps hybrid—was conspicuously good, while L.-C. Euripides, L.-C. Perfection, Cattleya Lady Veitch, C. Jupitus, Brasso-Cattleya Cliftoni var. magnifica, Brasso-Laelio-Cattleya Vashti and Epiphronitis Veitchii were all finely shown.

Messrs. H. G. Alexander, Ltd., made a brave show of Cymbidiums in great variety. In such a fine collection it is only possible to mention a few that especially arrested our attention; these were C. Petrel, C. Ophir, C. Butterfly, with a glorious spike of flowers; C. Eagle, of lovely form, C. Rosanna, the old C. Lowio-grandiflorum, C. Bullfinch, of deep colour, C. Widgeon, C. Starling, very pretty and of unique colouring; C. Pauwelsii with three splendid spikes, C. Miranda, C. Bustard, and the round-flowered C. Merlin.

Another particularly fine display was made by Messrs. Sanders, who also made a special feature of Cymbidiums, embracing good plants of C. Ceres, C. St. Andre, C. Pauwelsii, C. Iris, C. Vesta, C. Ralph Sander, C. Egret, C. Erica Sander, C. Mary Sander and C. Holfordianum. This firm also showed Phalaenopsis amabilis var. Elizabethae, P. Schilleriana, Aerides Vandarum, Miltonias in variety, Coelogyne lentiginosa, Maxillaria luteo-alba, Epidendrum Stamfordianum, Lycastes and Odontoglossums.

Messrs. Charlesworth and Co. presented a very bright group, and although they showed Cymbidiums, they made Odontoglossums and Odontiodas a special feature of their exhibit. Among the Odontoglossums a few outstanding sorts were O. crispum in variety, O. Zulu, O. Minotaur, O. Venus, O. Camilla, O. Indian Prince and the pretty O. Réve d'Or. The chief Odontiodas were O. Lady Patricia Ramsay, O. Alcazar, O. Acis and O. Lydia. Other good things were Miltonia Vida, Odontonia Ceres and Brasso-Laelio-Cattleya Joan, with golden flowers.

In Messrs. Stuart Low and Co.'s group we noted good examples of popular Cymbidiums, Lycastes, Cypripediums and Dendrobiums, with good plants of Laelio-Cattleya Sladdenii, Platyclinis glamacea, Dendrobium linguaeforme and Odontioda Bradshawiae.

Messrs. Cowan and Co. showed a selection of Cymbidiums, Odontioda Bradshawiae, a fine series of varieties of Lycaste Skinneri, Cattleya Clotho, C. Tityus (very fine), Brasso-Laelio-Cattleya Grace, Dendrobiums and Odontoglossums.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. G. W. Leak, Mr. Charles E. Pearson, Mrs. Helen Lindsay Smith, Mr. D. B. Crane, Mr. William Howe, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. W. Cuthbertson, Mr. Courtney Page, Mr. A. E. Vasey, Mr. James B. Riding, Mr. W. B. Gingell, Mr. J. T. West, Mrs. Ethel M. Wightman, Mr. Arthur Turner, Mr. C. F. Langdon, Mr. E. R. Janes and Mr. W. D. Cartwright (Secretary).

Section B.—Mr. Gerald W. E. Loder (in the chair), Mr. W. J. Bean, Mr. W. G. Baker, Mr. George Harrow, Mr. G. Reuthe, Mr. A. Bedford, Mr. L. R. Russell, Mr. W. B. Cranfield, Mr. T. Hay, Mr. F. G. Preston, Mr. Mark Fenwick, Mr. Reginald Cory, Mr. Hiatt C. Baker, Mr. R. D. Trotter, Mr. E. H. Wilding, Mr. R. C. Notcutt, Lady Beatrix Stanley, Mr. Clarence Elliott, Mr. J. Comber, Mr. E. A. Bowles, Mr. G. Yeld, Mr. R. W. Wallace, Mr. C. T. Musgrave and Mr. N. K. Gould (Secretary).

Awards of Merit.

Clivia Ursula.—This is a very fine variety. It has a large umbel of rounded flowers of rich orange colour, paler in the centre. Shown by the Hon. Mrs. R. James, Richmond, Yorkshire.

Freesia Beauty.—A good spike of rounded, mauve-flushed flowers which have a few rays of the same colour and a yellow throat.

Freesia Maryon.—The perianth segments of this variety are more pointed, and they are of lilac colour, with a white throat.

Freesia Mrs. R. F. Felton.—This is a deliciously fragrant variety. It is of robust habit and has large, rounded flowers of pale creamy-yellow colour passing to pale yellow. All the Freesias were shown by Mr. G. H. Dalrymple.

Cultural Commendation.

Leucadendron plumosum.—A well-grown plant in a large-sized flower-pot was shown by the Hon. Mrs. Ryder (gr. Mr. William Lowe), Durns, Beaulieu, Hampshire.

Other Novelties.

In addition to those which received awards, Mr. G. H. Dalrymple showed several attractively coloured Freesias; the variety Tangerine was especially prominent. Mrs. Carl Holmes (gr. Mr. W. G. Penton), The Node, Welwyn, Herts., showed two good Anthuriums. A. Scherzerianum, var. Mrs. Carl Holmes has a very large, well-formed, crimson spathe, while the variety Mr. Carl Holmes has an equally large mottled spathe.

Groups.

On a considerable floor space, Messrs. L. R. Russell, Ltd., set up an attractive group of forced shrubs. The chief sorts were double-flowered Cherries, double Peaches, flowering Crabs, Lilacs, Brooms, Magnolias, and Ghent and Mollis Azaleas. Messrs. Patricks grouped a good selection of Conifers with Daphne Mezereum, Erica carnea and Gaultheria procumbens. Several very floriferous plants of Japanese Azaleas, notably the varieties Hatsigiri, Alice, Atalanta and Cleopatra, were displayed by Messrs. D. Stewart and Son, who also had good bushes of Rhododendron praecox, with Snowdrops, Iris reticulata, Muscari and other spring flowers.

At the end of one of the tables, Messrs. Waterer, Sons and Crisp made an attractive display with Osmanthus Delavayi, Rhododendron praecox, several of the dwarf Irises, such as I. reticulata and its Persian forms, and Iris Sindpers. They also had good batches of Saxifraga Myra and S. Jenkinsae. Messrs. Hollambys staged a number of plants of Gaultheria procumbens, well-furnished with bright fruits, Primula Purple Splendour and Daphne Mezereum. In a boldly arranged, little rock garden, Messrs. Casburn and Welch planted Saxifraga Burseriana sulphurea, S. B. tridentata, S. Irvingii and Iris reticulata. The Misses Hopkins had many good blue Primroses in their rock garden.

In a pleasantly designed sandstone rock garden, Messrs. W. Wood and Son planted good breadths of Primula frondosa, P. Barrowby Gem, Scilla sibirica, Muscari azureum, Anemone fulgens, Narcissus minor and other spring flowers. Messrs. M. Prichard and Son had many very beautiful plants of Dicentra (Dielytra) spectabilis, with Magnolia stellata, and Viburnum Carlesii behind breadths of Primula dentata varieties, the double lilac Primrose, Saxifraga oppositifolia, S. Mrs. G. Prichard, S. Delia and S. R. V. Prichard.

At one end of a table space, Messrs. Barr and Sons had a particularly attractive grouping of spring flowers, including Crown Imperials, Narcissus canaliculatus, N. Queen of Spain, N. W. P. Milner, many of the valuable dwarf Irises, Dog's Tooth Violets and Cyclamen ibericum var. roseum. At one end, there was a very good selection of spikes of Lachenalia. Mr. George E. P. Wood placed a very large bush of Forsythia spectabilis in the centre of his exhibit, and also showed dwarf Conifers, Crocuses, Saxifrages, Primulas and double Daisies.

Messrs. W. Cutbush and Son made good use of a low tabling, where they grouped many excellent plants of Azalea indica and A. rustica varieties, with good Freesias. Messrs. Wallace and Co. contributed some very good Azaleas, Tulipa Eichleri, T. praestans, various Irises, Primulas and Crocuses, with Brooms and Japanese Maples. Mr. G. Reuthe staged Mimosas, Rhododendrons, Ericas and alpines. Mr. Clarence Elliott had dwarf Conifers, Crocuses, Saxifrages and Eranthis in his rock garden.

Near their Carnations, Messrs. Stuart Low and Co. grouped Camellias, Mimosas and Erica melanthera. Mr. G. H. Dalrymple had a good group of his coloured Freesias. The chief varieties were the new Maryon, Grey Dawn, of greyish-lavender colour; Tangerine, deep orange; Sunshine, bright yellow; and Mrs. R. F. Felton. Messrs. Sutton and Sons set up floriferous plants of multiflora Hyacinths in batches of pink, blue, white and scarlet.

Mr. George Prince again showed branches of the yellow Banksian Rose, with Fortune's Yellow, Austrian Copper, and cut blooms of Etoile d'Hollande. Messrs. C. Engelmann, Ltd., staged a good group of Carnations, including the varieties Mrs. H. Fellowes, Mrs. A. J. Cobb, Topsy, Spectrum and Radiolite. In their group, Messrs. Allwood Bros. had very good vases of Wivelsfield Claret, Wivelsfield Buttercup, Spectrum, Rapture and Shot Silk, and also showed bowls of the pretty little Dianthus Allwoodii varieties. Messrs. Stuart Low and Co. gave prominence to the varieties Thomas Ives, White Pearl, Eileen Low and Spectrum.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mr. C. C. Titchmarsh, Mr. H. Smith, Mr. W. B. Cranfield, Mr. Charles H. Curtis, Mr. J. S. Arkwright, Mr. Peter R. Barr, Mr. F. A. Secrett, Miss E. Willmott, Mr. A. W. White, Mr. George Monro, Mr. G. W. Leak and Mr. A. Simmonds, (Secretary).

There were no novelties exhibited before this Committee at this meeting.

Groups.

There were several bright displays of bulbous subjects on this occasion, Hyacinths and Narcissi being especially prominent.

Messrs. G. W. Miller had a charming group of Narcissi, among their most attractive sorts being Flame, Comrade, Campernellii gigantea, Dosoris and Betha, good trumpet Daffodils being King Alfred, Victoria, Empress and Dominion, together with several cream-coloured seedlings. At the front of this group were spikes of various Hyacinths, and grand clumps of Crocuses, in such varieties as Albion Stripe, purple, with paler stripes and shading; Maximilian, President Faure, General Gordon, Albion Purple, purpurea grandiflora and Baron von Bruno.

A large and splendid group of Tulips, Narcissi, Hyacinths and Crocuses, in ornamental bowls, was set up by Messrs. R. H. Bath, Ltd., Trumpet Daffodils were well represented, among them being such good sorts as Buxted, Glory of Noordwijk, Olympia and The Don. Other attractive Narcissi in this collection included Lucifer, Phyllida, Crystal Queen, the double-flowered Inglescombe, Lord Kitchener and Aspasia. Among Tulips were Yellow Prince, Ibis, Van der Neer, Enchantress, La Réve, William Copland, Prince of Austria, and De Wet, while Hyacinths included Gertrude, rose-pink; and Gigantea, pale pink. The varieties of Crocuses displayed in this admirable collection included purpurea grandiflora, Sir Walter Scott, Lilacens, Mikado and Hero.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (in the chair), Mr. H. S. Rivers, Mr. F. Bostock, Mr. P. D. Tuckett, Mr. G. F. Tinley, Mr. W. F. Giles, Mr. A. Poupart, Mr. J. Wilson, Sir W. G. Lobjoit, Mr. H. A. Prince, Mr. E. Laxton, Mr. W. Bullock, Mr. R. H. Hall, Mr. H. Markham, Mr. Edwin Beckett, Mr. W. H. Divers, Mr. E. A. Bunyard and Mr. A. N. Rawes (Secretary).

The Committee, before proceeding with the general business, placed on record its regret at the passing of Mr. P. C. M. Veitch, who died on Saturday last, and passed a vote of condolence to his relatives.

A seedling Apple was exhibited before the Committee, but was not of sufficient merit to receive any recognition.

Groups.

The only exhibit of vegetables at this meeting was a small collection of Onions, staged by Messrs. Sutton and Sons, the bulbs displayed being of perfect shape and in excellent condition. Among those with large bulbs were Ailsa Craig Selected, Improved Reading, and Selected Brown Globe, other varieties represented being Crimson Globe, Long Keeping, Reading, Bedfordshire, Sutton's Perfection, James' Long Keeping and Rousham Park Hero. There were also excellent baskets of Sutton's Giant and The Sutton Shallots, the latter a red-skinned sort, and also of Garlic bulbs.

READING GARDENERS'.

The fortnightly meeting of this Association was held in the Abbey Hall on March 4, when a large attendance of members, under the chairmanship of Mr. W. Broomfield, heard an interesting lecture on "The use of the Modern Dahlia in the Garden," by Mr. A. H. Fulker, The Gardens, Elmhurst, Reading, one of the most successful exhibitors of Dahlias in the district. In his opening remarks he said he had taken a great interest in the growing of Dahlias, especially since the war, for the cost of maintaining our gardens had doubled, and consideration therefore had to be given as to the best plants to grow to keep gardens gay throughout the summer and autumn at the least possible cost, and although not decrying the early-flowering Chrysanthemum and other summer and autumn flowers, in his opinion there was no other plant to equal the Dahlia for ease of culture, the brightness of its bloom, and continuity of flowering, for it could be had in bloom from June until cut down by frost. Full details were given of its propagation by cuttings, division of tubers and raising from seeds, also the preparation of the soil, planting, staking, and the cutting of the flowers for home decoration. In conclusion, the lecturer drew attention to the various types, and also the positions Dahlias should occupy in the garden. Among the varieties recommended were Dazzler, Picture, Dazzle, Our Annie, Sweet, Lovely, Reginald Cory, Trixie and Gatton Star. An animated and lengthy discussion followed, in which many practical hints were submitted. At the close, a hearty vote of thanks was accorded to Mr. Fulker for his useful and interesting lecture.

The exhibits at this meeting made a magnificent show, there being nearly two hundred flowering plants staged. In the non-competitive section, Mr. F. Townsend, The Gardens, Hillside, staged a splendid display of Primula malacoides, representing five distinct types, while Mr. A. W. Gower, The Gardens, Calcot Grange, had an equally fine display of the type of this Primula called the Hillside strain. Both were awarded First Class Certificates. Mr. W. Broomfield, The Gardens, Cliffe House, Mapledurham, gained an Award of Merit for several fine plants of Cyclamen. In the class for six sticks of Rhubarb there were five entries, the first prize being won by Mr. A. H. Dow, The Gardens, Sulhamstead House; second, Mr. G. Clark, The Gardens, Dyson's Wood; and third, Mr. M. Goddard, The Gardens, Bear Wood. In the class for six heads of Seakale there was only one entry, by Mr. P. H. Reed, The Gardens, Erleigh Park, but his specimens were well worthy of the first prize.

PROFESSIONAL GARDENERS'.

There was a large attendance of members at the meeting of the Harrogate Branch of this Association at Belvedere, Harrogate, recently, when, under the chairmanship of Mr. J. T. McCormack, Mr. Linham, of Halifax, delivered a lecture on "Rock Gardens."

Mr. Linham proved himself an authority on his subject, for he dealt with the construction, choice of stone, the site, and associating surroundings, in a lucid and comprehensive manner, while his choice of plants for the rock garden, and instructions for planting them, proved that he was familiar with them.

The lecture was followed by an interesting discussion, after which, on the proposal of Mr. Mennell, the lecturer was accorded a hearty vote of thanks.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

It transpired during the evening, that there was a greater amount of sickness among the members of this Friendly Society than at any period in its existence and, no doubt, this was responsible for the small attendance at the sixty-third Annual General Meeting on March 11 last, at the New Horticultural Hall, Westminster. Mr. Charles H. Curtis presided over the meeting, which was composed chiefly of members of the Committee which had met earlier in the evening.

The affairs of both sections of the Society are in a very satisfactory condition, so that the Reports of the Committee were unanimously adopted, and there was room for very little discussion. During the year under review, ninety-three adults and one juvenile have joined the Private Section, and its total membership is now almost two thousand. While the calls for sick benefit have been very heavy, the accounts for the year show a substantial balance on the right side, and the Trustees have been able to add materially to their investments on behalf of the Society. In view of this gratifying state of affairs, the Committee has given serious consideration to the possibility of two new benefits to members, which are the continuance of sick benefit to members over seventy years of age, and funeral benefits to members on the death of the wife. If, as is confidently anticipated, the coming Quinquennial valuation shows that these additions are justified, they will be recommended so soon as possible.

The Report also records the loss the Society has sustained through the death of Mr. F. Uxtoby, who had been an enthusiastic member of Committee since 1915, and whose loss will be felt. Mr. F. Lavender, of Messrs. Carter and Co., was elected to fill the vacancy. As is so often necessary with other societies, the Committee conclude their Report with an appeal to members to pay their contributions promptly. When the penalties of lapse in this respect are remembered it is difficult to understand how any member can knowingly allow himself to become in arrear.

In the State Section, the condition of the Society is also satisfactory, although when its advantages over other societies are realised a much greater annual addition to membership might be expected. During the year, sixty-three new members have been enrolled.

The officers and retiring members of Committee were all re-elected, Mr. Sleet was added to the Committee, thanks were tendered to the treasurer, the trustees and the horticultural press, and the meeting closed with an unanimous expression of great appreciation of the services of the Chairman, who has served the Society in that capacity for twenty-eight years—surely a record in horticulture.

TRADE NOTES.

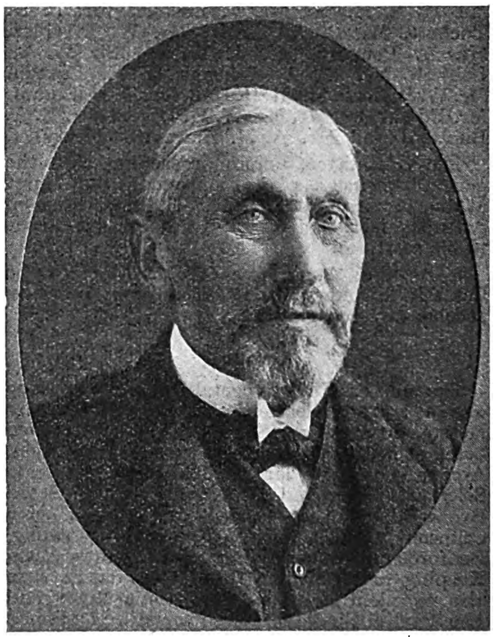
It is always a problem to keep pot plants perfectly healthy, and a notable contribution towards the solution of this problem is supplied by the makers of the Cret pot, which has a concave base, channelled to allow the water to run off easily and quickly, and is made with a very smooth surface inside, so that roots do not cling, and the risk of their breakage when re-potting is reduced to a minimum.

As lawn-mowers will soon be brought into action, the little booklet issued by Messrs. Alexander Shanks and Son, Ltd., comes opportunely as a reminder to purchase new parts for machines that have given long service, or obtain new lawn-mowers of up-to-date pattern. The firm offers hand, horse and motor-mowers, and the special triple, quintuple and septuple machines for use on golf-course fairways.

Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle*.

Obituary.

Peter C. M. Veitch, V.M.H.—It is with great regret that we record the death of Mr. P. C. M. Veitch, V.M.H., J.P., principal of the firm of Robert Veitch and Son which took place at his residence in Exeter on Saturday, March 9, at 3 a.m. Mr. Veitch was seventy-nine years of age, and had been ailing for some time, but the end came rather unexpectedly. He leaves one son, Mr. Norman Veitch, who is a Tobacco planter in northern Rhodesia, and three daughters, one of whom, Miss A. M. Veitch, B.A., is a director and actively engaged in the Exeter business. Of the two older sons, one, who was a judge in the Indian Civil Service, died in 1923; while the second, Major Leonard Veitch, was killed in action with the Devon Regiment in 1918. Mr. Peter Christian Massyn Veitch was born in South Africa in 1850, his mother being of Dutch-Huguenot descent; in fact Massyn was a corruption of her ancestors' name, Massena, one of Napoleon's generals. Mr. Veitch was the great grandson of the original founder of the house of Veitch, the records going back to 1792, about which time Mr. John Veitch came to Devon to make the park at Killerton for Sir Thomas Acland. The present firm of Robert Veitch and Son dates from 1863, and has been in Mr. Peter Veitch's hands since 1885, following the death of his father. Mr. Veitch entered his father's seed department at the age of sixteen, and spent the following fourteen years or so in various leading establishments in England and on the Continent. He also travelled extensively in Australia, Fiji, Borneo and the South Sea Islands on plant collecting missions. Some of his collections were lost at sea, he himself suffering shipwreck, but he sent a collection home in 1877, and in the same year he collected seeds of Ranunculus Lyalili (Mountain Lily) from Mt. Cook in New Zealand. From other parts of the same islands he collected several species of Celmisia, Veronica, Notospartium Carmichaeliae and other notable introductions which have found their way into private gardens all over the world. Mr. Peter Veitch was at this time collecting for his cousin, Mr. (afterwards Sir) Harry Veitch, of the Chelsea firm. It was at Coombe Wood Nurseries, under Ramsay, that Mr. P. Veitch developed a fondness for hardy flowering shrubs, which resulted in the Exeter nurseries becoming justly noted for the extensive collection cultivated there. The Victorian Medal of Honour was conferred upon him in 1916 in recognition of his great services to horticulture. Of a kindly, unassuming disposition, Mr. Veitch's death is a great loss to horticulture in general, and to the city of Exeter in particular. He was the senior magistrate for the city, and took a prominent part in the public life of both city and county. He was keenly interested in sport, being past President of the Rugby Club and President of the Cricket Club. He was a Governor of the Exeter Hospital, an enthusiastic member of the County Agricultural Society, County Agricultural Committee, and the Bath and West of England Society. He was also a frequent attendant at the Royal Horticultural Society's fortnightly meetings, being a member of the Fruit and Vegetable Committee. He was a past President of the Horticultural Trades Association, and quite recently took an active part in resuscitating the Devon and Exeter Horticultural Association, which is to hold an Autumn Flower and Fruit Show in November. A few introductions of note, raised by Mr. Veitch at Exeter, are as follow:—Calceolaria Golden Glory, C. Veitchii, Magnolia Veitchii, several hardy Nerines, Late Devonian Peach, and Exonian and Glory of Devon Peas, while he also introduced Rhododendron Dr. Stoker, Erica Veitchii and Veitch's Climbing French Bean to commerce. Miss A. M. Veitch has for some time past assisted her father in the business, thus carrying on the traditions of a famous family, which has had such a long and distinguished record in horticultural and botanical circles, and whose name is respected throughout the gardening world. Mr. Veitch was buried at Exeter on Wednesday, the service being held at St. David's Church, and attended by many old friends, and by representatives of all the public bodies of the city and county with which he was for so long connected.



THE LATE PETER C. M. VEITCH, V.M.H.

Edward Davidson.—On March 4, Mr. Edward Davidson, who for thirty years was Secretary and Treasurer of the Royal English Arboricultural Society, passed away at his home, the Estate Office, Hayden Bridge, Northumberland. Mr. Davidson, who was a magistrate for his county, was well known throughout the British Isles as a man well acquainted with matters pertaining to forestry. His father founded the Society fifty years ago, and it was he whom Mr. Edward Davidson succeeded as Secretary.

ANSWERS TO CORRESPONDENTS.

NAMES OF FRUITS.—*W. W. N.* 1, Broad-Eyed Pippin; 2, Welford Park Nonesuch; 3, White Nonpareil.

NAMES OF PLANTS.—*J. C.* Pittosporum tenuifolium, a variable species. *H. V. B.* Cyrtanthus Cooperi.

NECTARINE DIE-BACK.—*H. R. T.* The Nectarine shoots are suffering from die-back. Prune off and burn all badly infected shoots and spray the trees with Bordeaux mixture prior to the opening of the buds.

ORANGE LEAVES FALLING.—*W. W. N.* The trouble is certainly not due to a fungus. Only one further suggestion can be added to those offered previously (February 23, p. 151), and that is the leaf-fall may be due to faulty fumigation. Fumigation with hydrocyanic acid gas while the soil was excessively moist, may be responsible for the damage.

PEACH SHOT-HOLE FUNGUS.—*D. S.* The first spraying of your Peach trees with ammoniacal solution of copper carbonate, for the prevention of shot-hole fungus, should take place just as the leaves commence to expand, and should be followed by two or three applications at intervals of about a fortnight. The directions for mixing the solution are:—Mix one ounce of copper carbonate and five ounces of carbonate of ammonia together and dissolve it in about a quart of hot water. When thoroughly dissolved, add sixteen gallons of cold water.

RAISING ORCHIDS FROM SEEDS.—*V. S.* Practically all the well-known books on the culture of Orchids are out of print. It may be possible to obtain a second-hand copy of *The Culture and Management of Orchids* (Watson and Chapman); this deals with the raising of Orchids from seeds. The subject is, however, frequently referred to in these pages.

TOMATOS DISEASED.—*A.* Spray the plants at intervals from the seedling stage until the fruits are of fair size, with a liver-of-sulphur solution or weak Bordeaux mixture.

TULIPS AND IRISES DISEASED.—*R. B.* The Tulip and Iris bulbs are attacked by the fungus, Sclerotinia tuliparum. Infection arises underground and is due to the spread of mycelium arising from sclerotial bodies in the soil. The introduction of the fungus arises from sclerotia embedded beneath the bulb scales. Soil remains infected for three years after the removal of diseased bulbs. Contaminated potting soil should be subjected to steam sterilisation at 180° for three hours. The treatment of infected soil in outside borders with a two per cent. solution of formaldehyde is stated to be efficacious.

TULIPS FAILING.—In the first instance, your bulbs were not planted deep enough to obtain the best results, and it would also appear that the bulbs were of poor quality and immature. Lack of water might be partly responsible for their condition.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 43·4°.

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, March 20, 10 a.m. Bar. 30·3. Temp. 44°. Weather, Misty.

Concerning Chromosomes. MORE than a quarter-of-a-century has passed since de Vries startled the scientific world by the publication of his *Mutation Theory*. In two large volumes of German he gave an account of breeding experiments which he had been conducting with Evening Primroses for nearly twenty years previously, and outlined the conclusions of discontinuity in species-origin to which they led. These conceptions were one of the most important advances in evolutionary theory since Darwin, and everything that concerned the structure, history or behaviour of the North American genus Oenothera immediately became of prime importance. Cytological investigations of these forms began almost immediately, and in 1907 papers on the chromosomes of Oenothera commenced to appear. It was natural that investigators should scrutinise the germ cells of these plants and their sharply-marked derivatives or mutations, to see if any visible change had occurred there. By good fortune, Gates was able to announce that certain mutants had a different chromosome number from the parent (Oenothera Lamarckiana). A decade of work with which the names of Geerts, Gates, Lutz, Davis and other investigators were connected, led to the cell theory of mutation as developed by Gates in *The Mutation Factor in Evolution* (1915). Here it was recognised that each mutation represented a particular kind of nuclear change; in some mutants, such as O. lata, a single extra chromosome was present; in O. gigas the whole series had been doubled, and certain others, such as O. brevistylis and O. rubricalyx, were Mendelian mutations in which the visible chromosome morphology was unchanged and the inheritance in crosses was that of a simple Mendelian recessive or dominant. The occurrence of irregular divisions, by which an extra chromosome finds its way into a pollen grain which afterwards fertilises an egg and produces a plant such as O. lata or O. oblonga or O. scintillans, with fifteen chromosomes, was discovered as early as 1908. This process, by which one germ cell gets both members of a pair of chromosomes, is now called non-disjunction, and is known to occur in various plants and animals. De Vries and Gates[*] have recently published an account of all these (trisomic) forms. Since the genus Oenothera has seven pairs of chromosomes as its fundamental number, seven such primary trisomic types are to be expected, in each of which a different chromosome would be present in triplicate. They are O. cana, O. lata, O. liquida, O. pallescens, O. pulla, O. scintillans and O. spathulata, differing widely in their external characters, and gradually recognised over a period of years. In addition, there are three accessory trisomic mutants: O. albida, a weak form which appears in the offspring of O. lata, and O. oblonga and O. persicaria, both of which are derived in considerable numbers from O. scintillans. Similarly, it was shown in 1909 not only that O. gigas was a tetraploid mutation with twenty-eight chromosomes (4n), but that it was a cell giant. This was the starting point of the amazing results which have developed in the last twenty years, showing that polyploidy, or the occurrence of chromosomes in multiples of some basal number, is found with extraordinary frequency in the genera of flowering plants. It is known, for instance, in the species of Roses, Wheat, Oats, Docks, Chrysanthemums, Clovers, Maples and a long and constantly increasing list of other genera. Thus polyploidy is a principle which must be considered in connection with the evolution of the species in many genera of plants. Here is a most interesting form of discontinuity in the cell structure of related species—a frequent cause of partial or complete sterility when related species are crossed. The higher forms of polyploidy are frequently accompanied by apogamy and other aberrant forms of reproduction. Investigations with Oenothera have led to many other developments in genetic theory. The Oenotheras have notoriously been a law unto themselves and have shown more non-conformity to ordinary Mendelian behaviour than any other group of plants. It was at first supposed that O. Lamarckiana might be a garden hybrid, and that the peculiarities of its behaviour could thus be accounted for. But since wild species have been found to show the same sort of heterozygous conditions and to produce some of the same mutations, this view has had to be given up. In a recent monograph[†] all of the cytological investigations with this group of plants, in so far as they have a genetical bearing, have been summarised. From this it is seen that every part of the life cycle, including meiosis, pollen development, pollen tube growth, embryo sacs and their formation, ovules, fertilisation, embryo and seed production has been minutely scrutinised with significant results. Renner first showed that half the seeds in many species are empty or contain abortive embryos. This and other discoveries have led to the view that many species of Oenothera are permanently heterozygous or hybrid. Twenty years ago it was shown that the chromosomes of Oenothera are arranged end-to-end during meiosis, to form a continuous spireme or thread which then segments into a chain of fourteen chromosomes. More recently it has been found that delicate connections between these chromosomes persist into the reduction division. Instead of the pairs of chromosomes being free from each other, as is usually the case, one or more pairs remain connected, even after they are oriented preparatory to their separation. In other words, linkages persist between the chromosomes, and these linkages determine that the chromosome pairs will not undergo free assortment, as in ordinary Mendelian segregation, but that a restricted amount of assortment or no free assortment at all will occur, according to the number of chromosomes linked together. Several wild species are now known in which all the fourteen chromosomes remain linked in a single zigzag ring, alternate members of which pass to opposite poles. O. Lamarckiana and certain other species have one free pair and a ring of twelve, while in O. grandiflora all seven pairs are free. It is also found that the mutations show different linkages from the parent species. Thus the mutant O. rubrinervis has four free pairs and a ring of six. Again, in hybrids between species new fixed chromosome linkages are formed. These important recent discoveries, in which many investigators have taken part, open out new fields in the exploration of the relations between chromosomes, heredity, mutations and the evolution of species. A few indications of similar chromosome linkage have been found in other plants. Among the genetic peculiarities of Oenothera which require explanation are: (1) the fact that the species usually breed true (apart from mutations), although they are found on crossing to be heterozygous; (2) the fact that in many species half the seeds are empty and half the pollen and embryo sacs non-viable; (3) the fact that in crosses twin types commonly appear instead of free assortment of all the differences in the offspring. As already indicated, there is some evidence that the amount of segregation in crosses may be correlated with the number of free, unlinked chromosome pairs. To explain the origin of species such as O. Lamarckiana, which are a heterozygous combination of two types, both of which are non-viable in the homozygous condition, Professor Ruggles Gates formulates the hypothesis that pairing and linkage have taken place between non-homologous chromosomes in the hybrid. Thus, we would have the picture of wild species arising in Oenothera through hybridisation, and later breeding true because of the re-arrangement between chromosome pairs and the development of new linkages. Thus, the investigation of minute details of structure in the germplasm leads to new points of view regarding the evolution of species. Chromosome numbers are already a matter of practical concern to the horticulturist; chromosome linkages may become so in the future.

Dahlia coronata.—The Mexican Dahlia coronata, Hort., referred to in *The Gardeners' Chronicle* and other horticultural publications so far back as 1908, is very fully described in the current issue of the *Kew Bulletin* (No. 2, 1929). This species has pinnate leaves and orange-scarlet flowers. Originally, D. coronata was considered to be a form of D. coccinea,

[*] Hugo de Vries and R. R. Gates, 1928. A Survey of the Cultures of Oenothera Lamarckiana at Lunteren. *Zeits. f. Abst. u. Vererb.* 47: 275-286, figs. 5.

[†] Gates, R. Ruggles, 1928. The Cytology of Oenothera. *Bibliographia Genetica*, Vol. 4, pp. 401-492, figs. 39. Martinus Nijhoff: 's. Gravenhage.

Cav., but although it is near the latter species, the authorities consider it deserves specific rank, and that the original horticultural name of D. coronata should be retained.

The North-east Coast Exhibition.—We learn that Mr. J. E. Grant White has been commissioned by the Empire Marketing Board to organise an exhibit of British horticulture at the North-east Coast Exhibition, to be held throughout the summer at Newcastle-on-Tyne. There is no charge for space at the exhibition, and the Empire Marketing Board is offering to plant and maintain exhibits if so desired. Many colonial visitors are expected at the exhibition, which should present an excellent opportunity for British nurserymen to display their wares and skill. Applications for space and for particulars should be addressed to Mr. J. E. G. White, 7, Victoria Street, London, S.W., at an early date.

Albury Downs, Surrey.—The Duke of Northumberland (Lord of the Manor of Albury, Surrey) has, by revocable deed, given the general public access to the portion of Albury Downs situated within the parish of Albury, an area of considerable extent adjoining Newlands Corner. A sub-section of the deed makes it a summary offence to take vehicles, including motor-cars, on to the Downs.

Activities of the Forestry Commission in the Grampians.—Some 12,000 acres of land have been acquired by the Forestry Commission in the Grampians. About 4,000 acres are considered suitable for afforestation purposes, and it is hoped that part of the area unsuitable for such purposes will be made available for public recreation and transferred to the National Trust.

Medal Awards of the American Peony Society.—During the past season, and as recorded in its recently issued *Bulletin* for December, 1928, the American Peony Society awarded Gold Medals during the past season to Mr. A. P. Saunders, Clinton, New York, in recognition of his success in hybridising Peony species; to Mrs. Edward Harding, Plainfield, New Jersey, for the work she has done to promote interest in the Peony by the publication of two splendid books devoted exclusively to the Peony; and to Indian Spring Farms, Baldwinsville, New York, for the best collection of Peonies, in not over one hundred varieties, exhibited at the Boston, Massachusetts, Show.

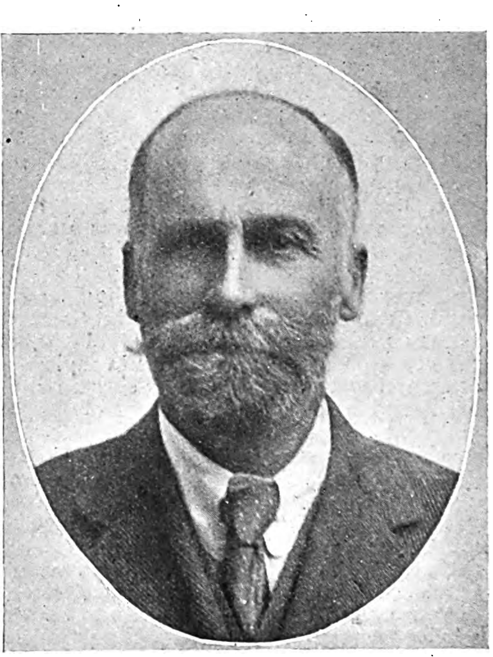
Portsmouth Horticultural Society's Summer Show.—The Summer Show of the Portsmouth Horticultural Society, to be held on Southsea Common on July 24, 25 and 26, should prove an event of outstanding interest, judging by the Schedule recently received. The five sections embrace, in all, nearly eighty classes, and, besides the many valuable money prizes, there are numerous trophies offered, including the Rowlands Cup, value fifty guineas, for the best non-competitive trade exhibit; the Lord Mayor of Portsmouth's Challenge Cup, for the best exhibit in Section 2; the *Evening News* Challenge Trophy, and several others.

Bush Fires near Adelaide.—Extensive bush fires occurred recently in the Adelaide Hills, to the east of Adelaide (Australia), and before the fires could be brought under control damage amounting to thousands of pounds was done. The fires raged on a fifty-mile front, and the destruction of orchards, pastures, fencing and stock is reported to be very heavy; one farmer alone had a thousand acres burnt.

Fifth International Congress Cambridge, 1930.—All motions for additional articles or amendments to the Rules adopted in 1905-10 must be in the hands of Dr. John Briquet, Conservatoire Botanique, Geneva, Switzerland, before September 30, 1929, if they are to come before the Congress of 1930, to be held at Cambridge, England. Such additions and amendments must be drafted as briefly as possible in Latin, English, French, German or Italian, and at least one hundred copies must be presented. According to the decisions of the Brussels Congress, 1910, only motions relating to new points which were not settled in 1905 and 1910 can be presented. Motions which do not answer to these conditions may only be discussed at Cambridge if the Congress so wishes.

Investigation of Weed Problems in U.S.A.—The annual losses from weeds in the United States of America are estimated at billions of dollars, and so vital is this problem that the Agricultural Service Department of the Chamber of Commerce has decided upon an extensive survey and study of the situation. The Service Department will co-operate with the American seed trade, and possibly with the U.S. Department of Agriculture and farm organisations. Seed law reforms will be considered, and weed conditions on farms, road-sides, etc., will be studied with a view to determining methods for weed eradication.

Mr. Cecil H. Hooper, F.L.S.—The reader of a recent paper before the Royal Society of Arts—which will appear in our next issue—Mr. C. H. Hooper, was educated at Marlborough College; Lycée de Versailles; and the Royal Agricultural College, Cirencester. He considers that the School Natural History Society at Marlborough created in him a great love of nature. He has read papers before the Royal Horticultural Society on: "A Year among the Orchards of Nova Scotia" (1899); "The Commoner Birds of our Gardens, their habits and foods" (1907); "The Influence of Geology on Horticulture" (1908); "Observations on the Blossoming of Fruits" (1910); and "The Pollenation and Setting of Fruit Blossoms" (1912). He is a member of the Scientific Committee of the R.H.S. and a Fellow of the Linnean Society. When the Horticultural College, Swanley, was commenced (1889), he taught surveying, geology and zoology. Later, he took Highlands Farm, Swanley, but continued to teach surveying for ten years. At Swanley he planted some sixty acres of different kinds of fruits; was secretary of an Experiments Committee which tried various manures and sprays on fruits and vegetables, and became secretary of the North-west Kent Fruit-growers and Market Gardeners' Association. Being asked to write a book on fruit farming, he wrote *Fruit Farming, Practical and Scientific*, which was published in 1912; the edition soon sold out, and a second edition was published in 1921. Mr. Hooper spent one year among the fruit farms of Nova Scotia, Canada, pruning, spraying and packing fruit; he also attended lectures at the School of Horticulture of the Nova Scotia Fruit Growers' Association; and brought back, and later imported, Canadian and American orchard spraying machinery (1898), which he believes to have been the first machinery for spraying high trees used in England. He also imported Bank's Red Gravenstein Apple trees, which grew well, but have since been re-grafted. In 1907, Mr. Hooper was appointed Librarian at the South-eastern Agricultural College, Wye, Kent. The Library is part of Wye College, built in 1445. His work there is considerable, interesting, and, he believes, useful. The College Easter vacation has afforded him opportunities for observation of, and experiments with, fruit blossoms, which he began in 1908. His object at first was to try to find out at which stage fruit blossoms were most susceptible to frost. In 1910 he had the advantage of assisting Mr. W. O. Backhouse in his pollenation trials on Apples, and recording his results at Wye. Several fruit growers have given Mr. Hooper the run of their farms, and carefully labelled the varieties for observation and experiment. Mr. W. S. Erle-Drax has also kindly allowed experiments in his beautiful fruit garden at Olantigh, Wye, where his gardener, Mr. Bond, grows fruits so well, and where a large number of the best varieties of fruits are grown. In 1928, Mr. E. A. Bunyard allowed Mr. Hooper the use of the Allington Nurseries for recording the order of flowering of varieties and pollenation experiments.



MR. CECIL H. HOOPER, F.L.S.

Legacies to Gardeners.—The late Miss Charlotte Maria Boyd, of Home Leigh, Cogham, who died on February 6, 1929, left £200 to her gardener, Mr. Alfred Sherlock.—The late Mrs. Mary Abb Parker, of Broomfields, Wilmington, Kent, who died on December 30, 1928, left £50 to her gardener, Mr. Arthur Mott.

Agricultural Scholarships.—The Ministry of Agriculture and Fisheries is offering 130 scholarships for courses at farm institutes, agricultural colleges, veterinary colleges and universities, for the sons and daughters of agricultural workmen and other persons engaged in agricultural work who are in a similar economic position. The scholarships enable young agricultural workers to improve their technical knowledge, so that in later life they may have a better chance of making headway in the industry on which their livelihood depends. Since the commencement of the scholarship scheme in 1922, 841 men and women have been assisted, and the results of training are encouraging. A large number have succeeded in improving their positions, the posts ranging on the practical side from foreman to estate manager, and on the educational side from assistant instructor to government inspector. The selection of candidates is by interview; no written examination is required. Practical experience in agricultural work is a very desirable preliminary to the courses of instruction—except scholars proceeding to universities direct from secondary schools—and, other things being equal, preference is given to applicants who have a good knowledge of ordinary farm work, or dairying, horticulture, or poultry-keeping, as the case may be. The value of the scholarships is sufficient to enable the recipients to attend the various institutions, without cost to themselves or to their parents. Information about the scheme, including a leaflet outlining the careers open to scholars, and forms of application, may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W.1, or locally from the offices of county councils. The last date for receiving applications is April 30, 1929.

A Gift to Cowes, Isle of Wight.—The Cowes Urban District Council has accepted the generous offer from Mr. Herbert J. Ward, of Egypt House, Cowes, of Northwood House and land in its vicinity, comprising some twenty-six acres. It is proposed to convert the house, which was built in 1838 and during the war was used as a Red Cross Hospital, into a town hall and municipal offices, with rooms for public entertainments, etc., and the land will be laid out as a public pleasure ground, for which it is admirably adapted as it is accessible from all parts of the town. Mr. Herbert Ward is a grandson of Dr. W. G. Ward, who gave Cowes its recreation ground many years ago.

South African Gladioli. — An interesting account of the South African Gladioli is given by Mrs. L. Bolus in the *Journal* of the Botanical Society of South Africa (Part XIV, 1928), and accompanying the article are coloured illustrations of Gladiolus crassifolius, G. Stanfordiae, G. gracilis, G. Pageae, G. coccineus, and an unnamed species, with pale rose-tinted, violet flowers, one specimen of which was collected in April, 1918, by Mr. N. S. Pillans on the Cape Flats, near Paarde Vlei, but it has not been seen since. Up to the present, some one-hundred-and-thirty Gladiolus species have been identified in South Africa, and it would appear there are many more to be discovered yet; these Gladioli may be divided into two important sub-divisions, *i.e.*, those with typical sword-shaped leaves, and those having narrow, grass-like foliage. Various distinctive characters of some of the species are discussed, and the order of flowering of the popular species is given. The New Year is heralded in the mountains by the Christmas Painted Ladies (G. Pappei), which are followed by the Autumn Painted Ladies (G. tabularis), in February. The succession is carried on from the end of March to early May on the lower slopes by the Little Pink Papies (G. brevifolius),and these are followed by the Brown Afrikanders (G. maculatus), which bloom throughout June. In July there are the Little Blue Papie (G. gracilis), Blue Vlei Papie (G. biflorus), Small Brown Afrikander (G. tenellus), Gold Papie (G. aureus), Pink Papie (G. villosus), Blue Afrikander (G. recurvus), Painted Lady (G. debilis), Kalkoentjes (G. alatus) Pink Bell (G. inflatus), and Aandblom or Large Brown Afrikander (G. grandis). The most beautiful of all follows these, namely, the Broad-leaved Painted Lady (G. blandus), which brightens the mountain slopes, while on the flats flowers the quaint, sand-loving G. arenarius. Mrs. Bolus's contribution to the literature of the Gladiolus makes interesting reading throughout, while, from a technical point of view it is also of considerable value.

The Common Green Capsid Bug.—This insect pest (Lygus pabulinus) is widespread throughout this country, being found on a large number of wild and cultivated plants, both herbaceous and woody. A full account of its life history, together with a description of the damage it does and suggestions for control, are given in the March issue of the *Journal* of the Ministry of Agriculture (Vol: XXV), by Mr. F. R. Petherbridge, of the School of Agriculture, Cambridge. Currants, both Red and Black, Gooseberries, Apples, Pears, Plums, Cherries, Peaches, Raspberries and Strawberries are attacked by this Capsid, together with Potatos, Beans—Runner, Dwarf and Broad—and Roses, while in the hedgerows, beside the herbaceous plants, it can chiefly be found on Blackberries and wild Roses, but it also attacks Hawthorn, Privet, Ash, Elm and Sycamore. In the herbaceous border its presence may often be detected on Dahlias, Salvia splendens, Fuchsias, Chrysanthemums, Marigolds, Michaelmas Daisies and Poppies, the foliage of Dahlias and the Salvia often being seriously disfigured. Among weeds it attacks are the various Bindweeds, the Creeping Buttercup, White and Red Dead Nettle, Polygonums, Docks, Groundsel, Solanums, Sow Thistle, Dandelions and Stinging Nettle; Chickweed, Shepherd's Purse and Veronicas are not attacked. There are two generations of this Capsid per annum. Eggs are laid on woody plants in the autumn, migration usually taking place in spring to herbaceous plants, upon which the summer eggs are laid, the second generation returning to the woody hosts for the laying of winter eggs. Mr. Petherbridge states that the Common Green Capsid Bug is readily killed by contact washes, as is the Apple Capsid Bug, but it is difficult to reach the bugs with the wash. They fall quickly to the ground when disturbed, and as Currant bushes are usually very leafy, spraying them often gives poor results. The best method is to shake the bushes and then spray the ground beneath them very thoroughly. The spraying should be done after all the bugs have hatched, about the time when the petals of Bramley's Seedling Apple begin to fall. The best wash to use at present is of eight ounces of nicotine to one hundred gallons of water, together with a spreader, which may be soft soap where the water is soft or of ordinary nature, at the rate of 8 lbs. to 10 lbs. per one hundred gallons of water; or sodium caseinate or a similar material where the water is very hard. The spray should be applied with a high-pressure pump, through a coarse nozzle. Spraying for the second generation is not considered profitable. In the case of Apples, the trees and the ground beneath should be sprayed immediately after blossoming. In small gardens an economical way of dealing with the bugs is to shake them off the plants on to sacking or sticky trays, and destroy them.

Appointments for the Ensuing Week.—Monday, March 25: Birmingham and Midlands Gardeners' Association's lecture. Tuesday, March 26: Royal Horticultural Society's Committees meet; Royal West Renfrewshire Horticultural Society's meeting (two days). Wednesday, March 27: Newcastle and District Horticultural Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Khasia Orchids.*—Dr. Hooker, in his travels in the Khasia mountains, mentions Eria, Coelogyne (Wallichii, maculata and elata), Cymbidium, Dendrobium, Sunipia and other beautiful air plants, as growing at the top of the Kolleng rock, flowering profusely; and though freely exposed to the sun and wind, dews and frosts, rains and droughts, they were all fresh, bright green and strong, under very different treatment from that which they are exposed to in the damp, unhealthy, steamy Orchid houses of our English gardens. Vol. II, 294. "Vanda caerulea grows in profusion, waving its panicles of azure flowers in the wind. As this beautiful Orchid is at present attracting great attention, from its high price, beauty and difficulty of culture, I shall point out how totally at variance with its native habits is the cultivation thought necessary for it in England.* The dry grassy hills which it inhabits are elevated 3,000 to 4,000 feet; the trees are small, gnarled, and very sparingly leafy, so that the Vanda which grows on their limbs is fully exposed to sun, rain and wind. There is no moss or lichen on the branches with the Vanda, whose roots sprawl over the rough bark. The atmosphere is, on the whole, humid, and extremely so during the rains; but there is no damp heat or stagnation of the air, and at the flowering season the temperature ranges between 60° and 80°; there is much sunshine, and both air and bark are dry during the day; in July and August, during the rains the temperature is a little higher than above, but in winter it falls much lower, and hoar frost forms on the ground. Now this winter's cold, summer's heat, and autumn's drought, and above all, the constant free exposure to fresh air and the winds of heaven, are what, of all things, we avoid exposing our Orchids to in England. It is under these conditions, however, that all the finer Indian Orchideae grow, of which we found Dendrobium Farmeri, Dalhousianum, Devonianum, etc., with Vanda caerulea; whilst the most beautiful species of Coelogyne, Cymbidium, Bulbophyllum and Cypripedium inhabit cool climates, at elevations above 4,000 feet in Khasia, and as high as 6,000 to 7,000 in Sikkim." *Dodman.*

* We collected seven men's loads of this superb plant for the Royal Gardens, at Kew, but owing to unavoidable accidents and difficulties, few specimens reached England alive. A gentleman who sent his gardener with us to be shown the locality was more successful; he sent one man's load to England on commission, and though it arrived in a very poor state, it sold for £300, the individual plants fetching prices varying from £3 to £10. Had all arrived alive, they would have cleared £1,000. An active collector, with the facilities I possess, might easily clear from £2,000 to £3,000, in one season, by the sale of Khasia Orchids. *Gard. Chron., March* 25, 1854.

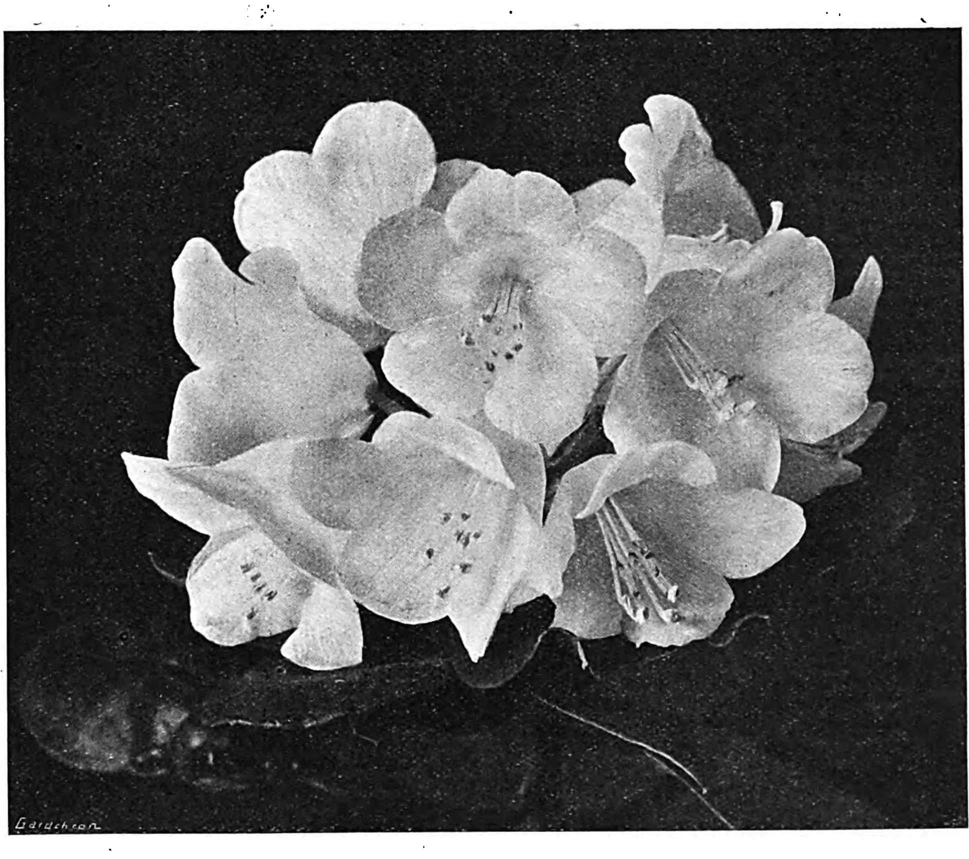


FIG. 105.—RHODODENDRON TELOPEUM.
(see p. 221).

Publications Received.—*Symbolae Sindicae.* Bot. Ergebnisse der Expedition der Akademie der Wissenschaften in Wien nach Südwest-China 1914-18; edited by Heinrich Handel-Mazzetti; in seven parts; parts IV and VI now ready; Vienna, Julius Springer, Schottengasse 4; price, part IV, RM. 28·80; part VI, RM. 10·00.—*The Crab-Apples and Nectarines of Japan*, by Yoshichi Asami, pp. 89, with 44 full-page illustrations and 50 plates; Marquis Nabeshima, Tokyo.—*Every Day in My Garden*, by F. Hadfield Farthing, F.R.H.S., pp. 414; Alfred A. Knopf, London; price 7s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Semi-deciduous Dendrobiums.—These free-flowering Orchids are making a fine display of bloom, and when fully expanded, the flowers will keep perfect for a long period if the plants are placed in cooler and drier quarters. Specimens in flower are attractive subjects for conservatory decoration, and will suffer no ill effects if used for house decoration for short periods, provided the plants are not exposed to cold draughts, and are only afforded sufficient water at the roots to keep the flowers and bulbs rigid; saturation of the roots will cause them to decay in the lower temperature. It is not advisable to place the plants in a high temperature directly after being in use for house decoration, but later, when the flower spikes have been removed, they should be grown in the warm house and lightly syringed on bright days, the surroundings being kept fairly moist. New growths will soon be produced, and when these are a few inches high and fresh roots are being formed, any necessary repotting may be attended to, using well-drained pots or pans. As Dendrobiums do not require a large amount of compost to grow in, the receptacles should be on the small side and the drainage ample; they root well in a mixture of three parts Osmunda or coarse A.1. fibre, and one part Sphagnum-moss, adding crushed crocks to keep it porous. The compost should be pressed firmly among the roots to allow the water to pass through freely; if it is left in a loose state, the fibre acts like a sponge and retains too much water; both the roots and compost quickly deteriorate under such conditions. After repotting, the stems should be supported by a neat stake and water afforded very sparingly until the roots are well established, when increased quantities may be given each time the compost appears dry. As the sunlight increases, more atmospheric moisture should be afforded by frequently damping the floors and syringing the pots and surroundings. Only light shading from very hot sunshine will be needed, and a free circulation of air should be provided so as to maintain a buoyant atmosphere, but cold draughts should be avoided.

Temperatures.—The increased amount of sunshine will cause the temperature to rise in all divisions during the day, to the benefit of most of the plants. A little extra damping down will be required on bright days, but any excess of heat and moisture should be avoided so that the plants will not be forced into growth unduly. Ventilation and shading should receive careful attention to avoid great fluctuations of temperatures. At this season, if it is necessary to lower the blinds to prevent injury to the foliage, it is advisable to close the ventilators for a time and so avoid a drastic fall in temperature. Large fires should not be made up in the early morning, as they are difficult to control during the rapid changes of weather generally experienced at this season.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Cucumbers.—The time has now arrived when Cucumber plants which have been in bearing all the winter may be removed, the houses cleansed, all old bottom-heat material removed and a clean start made with fresh young plants. If the weather is anything like seasonable, we may expect a few hours' sunshine daily to help all plants forward. The houses should be shut early, and plenty of water, at a temperature of 80° to 90°, syringed over the walls and other surfaces, will produce conditions most favourable to rapid progress. As Cucumbers delight in heat, a bottom-heat temperature of 75° to 80° should be maintained, while the day temperature of the house should be about 80°, rising to 85° to 90° after closing. Some growers never admit air, but I prefer to afford a little, if only for half an hour at midday, when the temperature may be maintained at fully 80°, but at this early season ventilation is a most troublesome business, especially in high, exposed situations. Where spring-sown Cucumber plants were given a good start they will now be making rapid progress, and must be kept steadily supplied with fresh rooting material, consisting of light turf, lime rubble or charcoal as the young roots come through. A stout, but by no means gross, growth is best calculated to give lasting results. Feeding in the early stages should be avoided, but once the plants commence bearing, mild and warm liquid manure may be given alternately with pure water, and also used for damping purposes. If the lateral growths have been pinched at the first leaf and early fruits are in demand, the second breaks may be allowed to retain their fruits until the most promising can be selected for developing, when the others, and those with male flowers, should be removed. As growth proceeds, remove all superfluous shoots and pinch back those bearing fruits at the first joint beyond if space is limited, but thin planting and semi-extension training is not only the most profitable, but is the most simple mode of growing Cucumbers.

Early Figs.—So soon as the fruits upon early pot Fig trees have completed the first swelling, progress for three or four weeks will be imperceptible, but if the roots are right, good work will be going on. In dealing with these tantalising fruits, the grower need not trouble about fertilisation, but the first step to success is liberal thinning. Maintain a night temperature of about 60°, with an average day temperature of 70° from fire-heat, and fully 80° on bright days with air and plenty of atmospheric moisture. Where bottom-heat is kept steady at 70° to 75°, forcing is safer and easier, and more rapid progress is made; an extra 5° will do no harm through the night, with 95° after closing the house early, when a good syringing with tepid water should be given. Give plenty of rich top-dressings of a mixture of rough pieces of turf, bone-meal and decayed manure, not packed too tightly.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Seed-sowing.—A large number of alpine plants may be raised successfully from seeds, and in collections of any size it is desirable to raise a number of the rare or new kinds by such means each year. A five-inch pot will usually be found large enough to provide sufficient stock. Cold frames which have a deep bed of ashes to prevent worms working their way into the pots, will be found most suitable for raising these hardy plants. Seeds of many of them are so minute that it is advisable to water the soil by plunging and allow it to drain before sowing the seeds. It is unnecessary and inadvisable to cover many of these small seeds with soil; the merest dusting of sand is sufficient. After sowing the seeds, place a sheet of glass over each pot and cover with paper until germination has taken place. Give attention to shading by mats during bright sunshine, for thousands of tiny seedlings are lost each year through being exposed to the bright sunshine and drying winds for a few hours. The seeds of these subjects often germinate irregularly, and it is a common practice to discard them after a few months on the supposition that they have failed, yet they may be perfectly sound. All that is necessary to do with such is to place them in the open, preferably at the base of a north wall, and provide them with water during summer, leaving them to get all the frost and snow possible in winter, and placing them in frames again the following spring. Seeds of many bedding plants may be sown during this week; larger sowings will be required this year to make up for the losses caused by the frost. Do not attempt to germinate them in too high a temperature; it is better to sow them a week or two earlier in a low temperature and give them cool treatment, than to force them into growth.

Climbers and Shrubs on Walls.—Now that the likelihood of hard frost is past, plants on walls should be attended to and the necessary pruning and tying-in done. A considerable amount of loss from the recent hard frost seems to be general, especially where tender plants have been grown in the open. Where dead plants have to be replaced, take the opportunity of thoroughly preparing the sites by enriching or replacing the old soil with fresh compost. This is especially necessary where narrow borders exist at the base of walls.

Sweet Williams.—These may now be planted where they are to flower. The best of the self-coloured varieties are Pink Beauty and Scarlet Beauty, but the old-fashioned Auricula-eyed sorts have much to recommend them if good strains are grown.

Pelargoniums.—Cuttings of Pelargoniums which are rooted should be potted into three-inch pots, and, in the south, may be placed in a cold frame during this month.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Grafting.—The grafting of fruit trees is one of the most ancient and important methods of preserving and increasing varieties, as well as of facilitating bearing. The methods of grafting are various, but for the purpose of these notes only two will be mentioned, viz., whip and tongue grafting and crown grafting. The actual time for carrying out this work is governed by the locality, but it is best done when the buds on adjacent trees are seen to be swelling freely. Success in grafting depends on having the sap moving freely in the stock, and dormant in the scion at the moment of insertion. These grafts or scions, whether they be from Apple, Pear or Plum, should be taken from trees of good quality and fruitfulness. They should be of the previous year's wood, well-ripened, and well furnished with growth buds, which may be recognised easily by being long and pointed, as distinct from the fruit buds, which are short and plump.

Whip and Tongue Grafting.—It is assumed in the case of young stocks that they were planted some twelve months before, and are therefore, well rooted and sufficiently established for working. The first operation is to cut back these stocks to about six inches from the ground level. Then, with a keen-edged pruning knife, make a long, upward, oblique cut from about three inches above the soil. Across the middle of this cut surface, cut a slit almost parallel with the slope, by a downward movement of the knife, thus forming the tongue. Next select the scion, with three or four buds, and make a similar slanting cut downwards, so nearly as possible the same length as that on the stock. Trim it carefully, if necessary, to form a perfect fit. Across the middle of this cut surface make an upward cut to form the tongue. The scion is now ready for insertion. Open the two tongues slightly and slip the one behind the other and push down gently so that they interlock. It is of the utmost importance that the bark or cambium layer of the stock should meet that of the scion on one side at least. Where the stock and scion are of equal dimensions success is almost assured, as the bark on both sides will meet and form a union; but it so often happens that the stock is much larger than the scion. Then it becomes imperative that the bark on one side of the stock and scion should be brought closely together to form a union. Bind the stock and scion firmly together with good, broad bast or raffia, covering all the cut surfaces with grafting wax, or prepared clay. Grafting wax, which is applied with a brush, should be sufficient to make the joint air-tight.

Crown Grafting.—Bush and old standard trees which have become unfruitful may be rejuvenated by "top-grafting," provided the roots and stems are in a healthy condition. In this way new and desirable varieties may be speedily increased. Such old trees should now be headed back, *i.e.*, the branches are cut back to eighteen inches or so from the main stem, and when the sap is well on the flow, later on, these branches may be shortened a little further still, the cut surfaces pared smoothly over, and "crown grafted." The scions are made as for whip and tongue grafting, but without the tongue. Make a cut three inches long in the bark of the cut-over branches, and push the wedge-shaped scion down between the wood and the bark until the cut portion on the scion has disappeared. Two scions on each branch will be quite sufficient. Bind the grafts in firmly with raffia, and wax over thoroughly to prevent damp and fungus disease getting into the cut surface.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Calceolarias.—Calceolaria Clibranii is a graceful plant for grouping, and to obtain the best results with it the specimens should be fed liberally with liquid manure, or failing this, a concentrated manure recommended for pot plants. The plants will now be producing their flower stems and will need supporting with neat stakes. Hybrid Calceolarias should not be allowed to become starved in their pots before liquid manure, which may be given on alternate waterings, is used. Late-sown plants may now be placed in their flowering pots and grown under the coolest conditions possible.

Carnations.—Cuttings of Perpetual-flowering Carnations which were rooted during January and potted singly into small pots, should now be ready for transference to three-inch pots. While it is essential that the young plants should not become pot-bound, it is wise to guard against overpotting. Mellow, fibrous loam that has been stacked for at least six months should form the bulk of the compost, and to this may be added one part manure from a spent Mushroom-bed, a little bone-meal, sharp, coarse sand, old mortar rubble and wood ash. The whole should be rubbed through a coarse sieve to ensure that it is thoroughly mixed, and then warmed to the temperature of the house in which the plants are growing. One crock placed at the bottom of the receptacle should suffice at this potting, and this should be covered with a little loam fibre. Pot the plants moderately firmly, pressing the compost with the fingers only, and leave the surface soil loose so that water will pass through evenly. Guard against potting the plants too deeply; only just cover the old ball of roots with the new soil, as deep potting often results in stem-rot. Before potting them, it is wise to go carefully over the young plants and ensure that the soil in which the plants are growing is well moistened, so that no water will be required directly after they have been potted. Stand the young plants, if possible, on a cool layer of ashes in a light house with a night temperature of about 50° to 55°. The first stopping of these Carnations should only be performed when free root action is taking place; therefore it is best carried out two or three weeks before or after this potting. The best time for the first stopping is when the young plants are growing freely and the roots have completely penetrated the soil. On the other hand, if the growths are allowed to become hard before stopping takes place, a disappointing break will result.

Browallias.—Seeds of Browallia speciosa var. major and B. elata and its variety alba, may now be sown. The Browallias are useful subjects for the conservatory as they bloom when flowers are none too plentiful. B. speciosa var. major grows best in an intermediate house, but the plants may be removed to a cool house when in flower.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Spring Cabbage.—Now that the weather is milder, the spring Cabbage bed may receive a dressing of sulphate of ammonia or nitrate of soda applied between the rows of plants and then hoed in. If there is a large area of these Cabbages half the bed, or a quarter, can be done at a time, at an interval of a fortnight, so that the Cabbages will be ready for cutting in succession. Cabbage plants which were wintered in the seed-bed may now be planted out to provide a succession.

Early Carrots.—A further sowing of Carrots may be made on a warm border, in ground that has been well dug and exposed to the recent frosts, and which, before sowing the seeds, should be worked with a cultivator to secure a fine tilth. Early Scarlet Horn and Early Nantes are two suitable varieties for sowing at the present time.

Potatos.—Another batch of early Potatos should be planted in well-prepared ground. Allow about twenty-four inches between the rows and draw the drills six inches deep. After the tubers have been set, and before they are covered, sifted wood-ash should be sprinkled in the drills, this being beneficial to Potatos. To produce exhibition tubers, choose only the very best sets, and if plenty of old, spent Mushroom-bed manure is available, work this well into the soil previous to planting the tubers. Keep the ground scrupulously clean by frequent hoeing, and exercise care when earthing up.

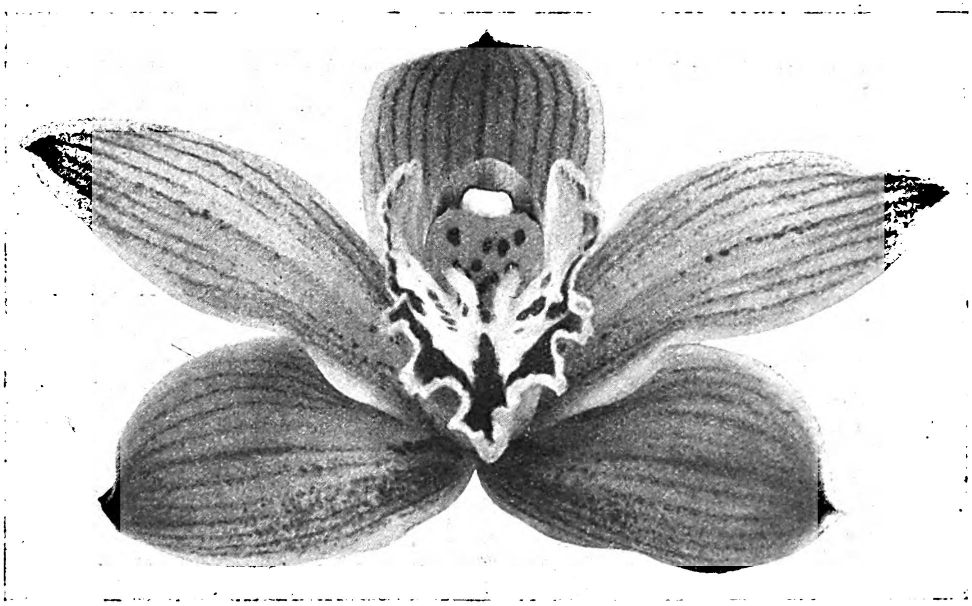

FIG. 106.—CYMBIDIUM RALPH SANDER, OLD QUARRY VAR.

R.H.S. Award of Merit, March 12. Flowers bronze, buff and pink. Shown by W. J. Burstow, Esq., Old Quarry, Haywards Heath (see p. 212).

Beetroot.—A sowing of stump-rooted Beet may now be made for early use. This crop should be sown on the warmest border in the garden, preferably on ground where it is walled in, as a walled-in garden is much warmer, and things grow more quickly with the shelter provided. Any Beetroots left in the ground should now be pulled and stored in ashes; they will keep for a considerable time.

Spinach Beet.—This vegetable has wintered well and is now commencing to grow. The Dutch hoe should be applied between the lines to open the surface. Likewise, Seakale Beet should be treated in the same manner. These vegetables are in great demand as a change from other green vegetables.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Early Potatos.—Where a suitable warm border can be made use of, a few rows of proved early Potatos should now be planted, provided steps are taken later to protect the young growths from late frosts. On heavy or wet soils plant the tubers rather shallowly and allow an extra inch or two between the rows to admit of earthing up. If used, artificial manures should be applied sparingly, but lime (air-slaked) and burnt soil or wood ashes are of great benefit.

Seakale.—Where grown from root-cuttings, this crop should be attended to at an early date. The cuttings which were removed from the forcing crowns at lifting time and prepared should now be calloused. If the plot has been dug or trenched previously, a good forking or hoeing will suffice now. Mark off the rows two feet apart, and make holes with a dibber just deep enough to allow of the crown of the cutting being covered. Drop one cutting into each hole, twelve to fifteen inches apart, and fill with sharp sand, quite covering the crown. A row or two of Seakale seeds should be sown each alternate year to supply fresh stock, as deterioration takes place if Seakale is grown too long on the same ground. Lilywhite is the best variety, but it is not quite so hardy as the common sort. When growth commences, keep the soil well cultivated on the surface, and if a plurality of crowns occurs, reduce to one when large enough to handle.

Montbretias.—The newer, improved varieties of these which were lifted and wintered in frames may now be replanted in the flowering quarters. They do not seem to be particular as to soil, doing well in most well-cultivated ground. Plant single corms from four to six inches apart, in rows twelve inches from each other. If the soil is very heavy, a little rough sand should be placed around the roots, and the whole bed well broken up previous to, or during the planting.

Gladioli.—Large-flowered, and also Primulinus or other Gladioli, should be planted in good, well-wrought ground. Light soil is to be preferred for Gladioli but heavy ground can be made to suit by the addition of sand, burnt soil, and vegetable or leaf-mould, mixed in with the fork or spade, and a little sand both above and below each corm at planting. It is a mistake to start Gladioli corms in pots or boxes under glass and to plant them out later; they do much better if planted permanently while dormant.

ALPINE GARDEN.

SAXIFRAGA GUTHRIEANA.

There are two forms of the rarely-grown Saxifraga Guthrieana, and one, in particular, S. Guthrieana var. variegata, appears to be practically out of commerce; at least, the writer has not seen it offered for some time. The typical S. Guthrieana is reputed to be one of the numerous hybrid Saxifrages, and to have derived its origin from the union of the hybrid S. Andrewsii with S. Aizoon. There is, possibly, no precise evidence of this, but it is quite probable, as we may gather from an observation of the green-leaved form. It resembles a plant of S. Andrewsii which has been stunted and reduced in size by unfavourable conditions. It has lost nothing, however, in the way of neatness, and is superior to S. Andrewsii in that respect. The pinkish flowers also resemble those of S. Andrewsii.

The main interest in this Saxifrage lies in its having produced a variegated-leaved form, which is of high beauty and much superior in every way to S. umbrosa var. variegata, the nearest approach we have to it in respect of variegation in Saxifrages. It is a really exquisite plant with its foliage wonderfully marked with pink, white and yellow, but it does not produce its flowers quite so freely as the green-leaved form.

S. Guthrieana and its variegated variety will grow in ordinary loam, and they are, I consider, the better for a little shade. The variegated form is not a vigorous grower by any means, and the suggestion made by an eminent writer on such plants that it should be grown in the alpine house is worthy of consideration. In the open I have had to protect it against birds, which appear to delight in tearing out the rosettes and leaving them lying on the path. It is a lovely plant which I have lost from this cause when absent from home for a week or two, only returning to discover, on several occasions, S. G. var. variegata withered beyond all hope of recovery. *S. A.*

SEDUM TERNATUM.

Although one of the best Sedums in cultivation, S. ternatum is not often well represented in gardens. The only explanation one can offer for this is that it is a species which does not flourish in the meagre, dry, sun-beaten soils which the Stonecrops are popularly supposed to enjoy. I find it needs rather moister conditions, with a fairly good, yet gritty and well-drained, root-run, and if the plants are not too much exposed, so much the better. With such treatment, S. ternatum can be most delightful, covering itself with a mass of foamy inflorescences throughout the later spring and early summer.

S. ternatum is a North American species, haunting rocky, open woods over a large range east of the Mississippi. Its leaves are roundly obovate, tapering to the base; they are usually in threes (hence the specific name), and those of the barren shoots, which latter form a loose rosette, are about half-an-inch wide, and very much larger than those on the flowering stems. This foliage is fleshy, glabrous, and a pale glaucous-green. Being evergreen, the rosettes of S. ternatum are attractive even in winter and the plant is perfectly hardy. The flowers, which are white, are borne in a claw-like cyme with three or four branches and they produce, as I have suggested, a pretty, scintillating mass of whiteness which endures over a period of several weeks.

This Sedum is quite distinct from most of its race, and so remarkably constant is it in character that no varieties appear to be in cultivation—not in commerce, at any rate. The only species which is likely to be mistaken for it is S. Nevii, which is, however, smaller in all its parts and more glaucous in the colour of the foliage; the leaves of the much closer rosettes are also more spathulate than those of the above, especially on the flowering stems, where they are almost oblong. S. Nevii appears to be closely allied to S. ternatum, and it needs similar conditions.

NERTERA DEPRESSA.

This little plant seems to be one of those things which are quite easy in the right place, and absolutely hopeless in the wrong one. Perhaps this is why it exerts such a strange fascination over most amateurs. But quite apart from that wayward temperament which so excites our gambling instincts, N. depressa is a charming plant. When its glossy, bright green carpet, which looks like a film of Helxine Solierolii, is dappled all over with its highly-polished and tawny, orange-scarlet fruits, which are as large as small Peas, it is exceedingly attractive. This crop, moreover, lasts for an extraordinary period. Last year, for example, some patches of N. depressa coloured their glowing berries in early August, and the plants were still carrying most of them in January of this year.

N. depressa is a New Zealand species and, if it is not perfectly hardy, it seems capable of enduring considerable frost. Some of my plants which were quite in the open came through last winter with very little injury, but some shelter is desirable in most places if the best results are to be realised. The specimens referred to are under a shelving rock with a northerly exposure. The soil is light but cool and damp, just the sort of place in which Liverwort loves to grow. Indeed, this pest is the only trouble which assails these particular plants, but an occasional picking-out of the enemy is sufficient to keep it from overwhelming the Nertera. The New Zealand Moss, as N. depressa is sometimes labelled when displayed in pots in shop windows, makes an attractive subject for partly shady places in a cool house, especially among Ferns. It is easily propagated by division, any rooted scraps growing freely if potted in sandy leaf-mould in the later summer, the pots being kept in a shady, closed frame for a week or so. *A. T. J.*

RANUNCULUS GRAMINEUS.

The merits of this Buttercup are quite rightly extolled by your contributor, *Kent*, in a recent issue of *The Gardeners' Chronicle* (March 2, p. 158), for although it is a yellow-flowering species of Ranunculus, it is quite distinct in petal from that of the ordinary type of yellow Buttercup. This is due to a feature which, when recognised, may make the plant more interesting to those who grow it. The upper surface of the petal is without the high polish which is such a distinctive feature of the common yellow Buttercup. Hence the epithet, "glossy," used by *Kent* in describing the flower is not exactly apt. The upper surface—the one exposed to view—of the petal of Ranunculus gramineus has a soft, refined texture, in contrast to the very shiny and somewhat aggressive character of that of the Buttercups of our pastures.

The texture assumed by the part of the petal exposed to view—usually the upper (ventral) surface—is one of considerable interest in floral evolution. Apparently the tendency is to advance from a smooth, somewhat shiny surface to a soft, velvety one. This is brought about by the epidermal cells becoming papillate. The highly-glazed petal of the yellow Buttercup would appear, on the other hand, to be an evolutionary advancement on its own. Instead of what might be termed primitive glossiness giving place to a velvety sheen, the shininess in this case has been greatly augmented by the production in the epidermal cells of a highly refractive oil, and by the formation below of a layer of cells densely packed with starch granules. A mirror-like effect is thus brought about.

The glossy type of petal so characteristic of the yellow Buttercup is probably unique among flowers. At any rate, the challenge is thrown out to anyone to bring to notice a petal of another genus so glazed. As already pointed out, Ranunculus gramineus is an exception among yellow species of the genus in not having highly-polished petals. It thus resembles the white Buttercups and flowers generally. From a study, not yet complete, of this large genus, the vast majority of the yellow species have been found to possess glossy petals. Besides Ranunculus gramineus and species allied to it, the only other yellow-flowering species that I have come across with non-glossy petals is the interesting Water Buttercup (R. multifidus, Pursh.) of North America. Perhaps R. asiaticus, the parent of our garden Ranunculuses, should be added to the exceptions, since yellow-flowering forms occur wild, although red is the common colour. It is strange that, so far as I know, there is no white-flowering species with glossy petals. Glossiness seems always to be associated with yellow petals. *J. Parkin, Blaithwaite, Wigton, Cumberland.*

HARDY ANNUALS.

Many of the popular annuals largely employed in the embellishment of our gardens need the aid of a frame for raising them in the spring to secure the best results from their use; but there is a long list of highly decorative plants which come into flower within a comparatively short period of time from the sowing of the seeds, that one may sow in the positions in which they are to flower with good results, and a note on a few of the most useful of these may be of interest at the present sowing season. A border of these hardy annuals will be a source of great interest and delight, for many of them have elegant form, attractive blendings of colour and refined appearance. It is essential, however, that the sites should be prepared thoroughly to enable the seedlings to send their roots down for moisture in the early stages of growth; and that the seeds should be sown thinly, while from the first the plants should be kept sufficiently thin to prevent overcrowding. The flowers of crowded plants will be poor and their period of display brief, but bold thinning will result in robust plants with ample foliage and well developed flowers yielding a floral display worthy of admiration

Argemone grandiflora is a graceful plant with spiny foliage and large, white, Poppy-like flowers, with brilliant yellow stamens, and Bartonia aurea (Mentzelia Lindleyi) is a good companion plant, with ornamental foliage and large, deep yellow blooms of great beauty. Cacalia coccinea (Emilia flammea) is seldom grown, but is a most attractive border annual, with brilliant orange-scarlet flowers much prized for cutting. The Calendulas or common Marigolds are exceedingly showy annuals for beds and borders and may be obtained in rich lemon and orange shades, double or single, the singles being the more attractive flowers. The Candytufts are of fine habit, are very profuse flowerers and are among the gayest, hardiest and most accommodating of hardy annuals. They flower in a very short time, remain in beauty a long period, are excellent for massing in beds and borders, and are admirably adapted for edgings, while their fragrance adds to their charms.

Centaurea cyanus, the annual Cornflower, is a charming garden plant and excellent for cutting and Centaurea moschata, the Sweet Sultan, is a delightful plant, producing large, feathery flowers in various beautiful shades of colour and of delicious fragrance.

The Clarkias are remarkably effective border plants which, while having no great range of colour, possess softness and delicacy of shade which is unique. Their elegant spikes of large, handsome, semi-double flowers are very decorative and distinct. Convolvulus minor, although so brilliant in sunshine, closes its blooms in the shade, but it is worth a place in the front of the border on account of the soft, velvety texture of the flowers. The Calliopsis are exceedingly graceful border plants, providing throughout the summer an abundance of elegant, showy flowers, their deep golden petals, with dark centres, making them very attractive. Besides the tall-growing varieties, there is a pigmy race forming perfect little bushes smothered with similar brilliant flowers.

The Eschscholzias bear brilliantly-coloured flowers which produce striking effects in beds and borders. They thrive in poor, dry soils where many annuals would not grow, and reproduce themselves freely from year to year. Phacelia viscida is a little-grown plant, but exceedingly beautiful and very effective, its intensely blue flowers giving it an unusual fascination. The Godetias are beautiful hardy annuals, forming sturdy little bushes covered with large, handsome, Malva-like flowers in a wide range of colours from white, through the various shades of pink, salmon, scarlet. and crimson. Although somewhat stiff, it is an excellent border plant, holding its flowers well up and furnishing abundance of colour. Gypsophila elegans and its varieties are very graceful plants of light, fairy-like growth, as fine as G. paniculata and equally useful in vases as a groundwork for heavier subjects.

The Sunflower, in its numerous varieties, is a highly effective plant in the annual border, the taller kinds, with their massive foliage and large flowers, occupying positions at the back of the border and giving it a touch of dignity, while the dwarf sorts form spreading bushes with small, graceful foliage and bear a multitude of small, elegantly formed flowers from early summer until autumn, giving an effective finish to the front of the border. The annual Larkspurs are also splendid plants for back positions in the border, and while not having the stateliness and dignity of the perennial Delphinium, their finely-cut foliage, handsome, erect spikes of semi-double flowers, and wide range of beautiful colours give them an appealing beauty all their own. Another tall-growing plant is the lovely Mallow, Lavatera splendens, which may be had in a soft, milky-white tint and in several shades of pink and rose. Linum grandiflorum coccineum is one of the most brilliantly-coloured summer annuals, with flowers of a glowing crimson; Limnanthes Douglasii is a beautiful little plant with dainty yellow flowers, edged with white, fine for edgings, and Gilia (Leptosiphon) hybridus is another tiny plant forming dense cushions, studded with pretty flowers ranging in colour from yellow to rosy-scarlet.

The annual Lupins provide another group of large-growing plants bearing handsome spikes of flowers in many striking colours. Matthiola bicornis, the Night-scented Stock, is a most useful plant, flowering in an amazingly short time from seeds, and emitting a delicious perfume perceptible at a considerable distance; and Nigella (Love-in-a-Mist), particularly the variety Miss Jekyll, is a very graceful plant, its lovely azure-blue flowers being partially hidden by the curious, fine, feathery bracts surrounding them. Charming effects may be obtained by associating Nigellas with Eschscholzias and some of the miniature Sunflowers. No summer-flowering plants can surpass the Tropaeolums in brilliancy of colour and freedom of flowering, particularly when grown on poor, dry soils. There are many varieties of dwarf, compact habit which carry their flowers well above the foliage and create masses of telling colours of wonderful effectiveness. Mignonette is a favourite plant with everyone and, besides being richly scented, some of the varieties have massive heads of coppery-red flowers which are very charming.

Nemophila insignis is probably the most popular annual grown, on account of its easy culture. In spite of its somewhat untidy habit it is very effective for beds, borders, or ribbons, its clear, light blue flowers, with white centres, making it very attractive. Another excellent blue-flowered annual is Phacelia campanularia, a charming plant producing a terminal raceme of intense blue flowers with conspicuous white stamens.

No collection of hardy annuals could leave out the annual Poppies, favourite flowers which are used extensively in beds, borders, shrubberies and woodland, where they are particularly good for distant effect. The Shirley strain is of light, graceful habit, with beautiful, satiny flowers in a wide range of delicate shades of colour, while the giant Paeony-flowered Poppies bear large, handsome, double flowers in various brilliant colours and are splendid border plants.

The plants noted above by no means exhaust the list of hardy annuals, but give a selection of those which flower in a relatively short time from seeds, require no glass or heat to bring them on, and afford material to fill an empty border and maintain an effective floral display during the greater part of the summer and autumn. *W. A.*

PLANTS NEW OR NOTEWORTHY.

FRITILLARIA KARADAGHENSIS.

THIS new plant hails from the Kara-dagh, a district near Tabriz in northern Persia, hence its specific name. It was first discovered by Mr. Egger in 1927, when dried material was forwarded to Kew and named by Dr. Turrill. But so far as can be ascertained, it was only in 1928 that sufficient material could be acquired in order to try it in this country. In that year, Mr. Gilliat-Smith, British Vice-Consul in Tabriz, sent bulbs to Messrs. R. Wallace and Co., The Old Garden, Tunbridge Wells, who grew them and exhibited them at the R.H.S. meeting on February 26, 1929, and afterwards presented the plants to Kew.

Fritillaria karadaghensis (Fig. 107) is a charming little bulbous plant, very near F. graeca, but somewhat lighter in colour and heavier in foliage. It is six to seven inches in height, bearing at the apex of each single stem one or two bell-like flowers some three-quarters-of-an-inch in length; the sepals and petals broaden from a quarter-of-an-inch at the base to half-an-inch towards the apex, recurving a little when fully opened and having a thickened ridge running down the centre of each.

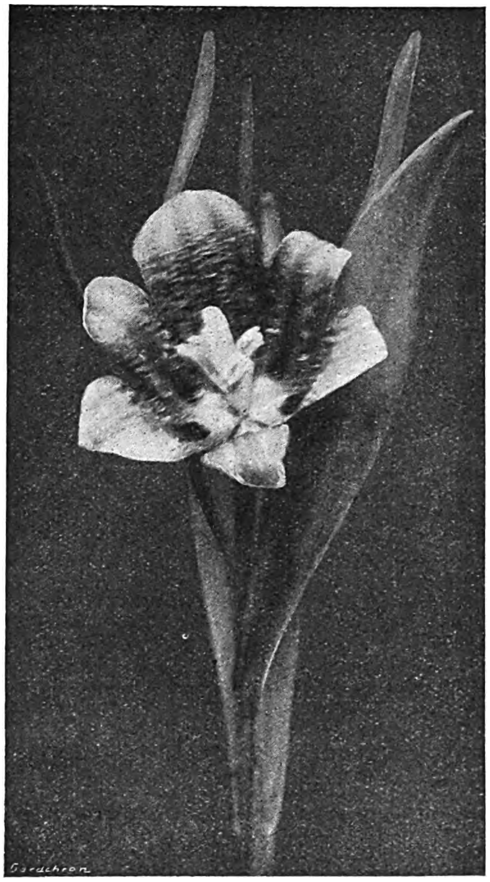

FIG. 107.—FRITILLARIA KARADAGHENSIS.

In colour the flower is a yellowish-green, speckled with reddish-brown, of varying intensity in the different flowers, the markings becoming deeper in colour and suffusing the whole flower as this passes from maturity. The style of pale yellowish-green is just a little longer than the stamens, sufficiently so to allow its three-rayed stigma to overtop the anthers when open, but not enough to show outside the bell of the flower when in its earlier stages. The leaves are lanceolate, from two inches to four inches in length by half-an-inch to three-quarters-of-an-inch in breadth, of a glaucous, bluish-green shade, arising singly at intervals of three-quarters-of-an-inch to an inch apart on the stem, but less towards the apex.

The plant ought to be perfectly hardy in some sheltered position, but, so far, no actual proof can be given of its hardiness in this country; it seems to prefer a well-drained peaty loam, and the pans of it that have already been grown are proof of its readiness to flower in suitable surroundings. *A. Edwards, Kew.*

RHODODENDRON TELOPEUM.

A SMALL plant of this species was shown by Lady Aberconway and the Hon. H. D. McLaren, Bodnant, at the Royal Horticultural Society's meeting on March 12.

Rhododendron telopeum (Fig. 105, p. 217) is one of the newer Chinese species collected by G. Forrest, and described by the late Sir I. Bayley Balfour and Forrest in the *Notes of the Royal Botanic Gardens, Edinburgh*, Vol. XIII, p. 61, 1920, where its locality is given as south-eastern Tibet, Tsarong Salween and Kui-chiang divide. This species belongs to the campylocarpum group. In the original description the flowers are given as bright yellow, but this was not borne out in the plant as exhibited, as the colour was pale yellow; this difference, however, may be due to climatic conditions, such as lack of light, or the plant may have been grown indoors. The growth is slender and twiggy in character, the leaves about five centimetres long, rounded or elliptical in shape, bright green above, and somewhat glaucous underneath; the petioles and small calyx lobes are more or less pubescent or glandular; the corolla, as in R. campylocarpum, is campanulate, measuring about three centimetres across.

Whether this species proves hardy, except in the more favoured parts of the country, remains to be proved. It may possibly have some value for hybridising, as a good race of yellow-flowered Rhododendrons for the garden is yet to be sought and is much desired. *F. C.*

INDOOR PLANTS.

BOUGAINVILLEA MRS. BUTT.

FOLLOWING an extended experience with this plant, I do not hesitate to bestow upon it unstinted praise as a permanent greenhouse decorative subject, or as a pot plant for general decorative work; for well-flowered examples clothing the pillars or trained to the rafters of a structure, are markedly beautiful, but not more so than are compact specimens grown in pots of seven or eight inches diameter. I find this beautiful Bougainvillea is prone to flower in a smaller state than will the majority of its congeners; the colour of the bracts is not easily described, but, perhaps rosy-crimson of a remarkably bright shade will nearly meet the case. The plant is vigorous, and the foliage ample and thick-textured. Cuttings root with ease and soon make serviceable flowering plants. *A.*

PLUMBAGO ROSEA.

INTRODUCED from the East Indies so long ago as 1777, this elegant plant is not so widely grown as its merits deserve, for few plants are more useful as winter-flowering subjects. Its large, oblong, almost amplexicaule leaves, above which are borne long, graceful spikes of soft red-coloured flowers, give the plant a refined appearance, and during the dull period of the year its attractive colouring is particularly valuable. Apart from its usefulness as a pot plant, it is also serviceable when cut, the slender spikes lending themselves admirably to table decoration and remaining fresh for a considerable length of time.

Although its country of origin suggests stove treatment, better results are obtained by growing P. rosea under cool conditions, and during the summer, from July to September, no more protection than a cold pit affords is necessary. The most useful plants for decorative purposes are obtained from spring-struck cuttings and these, if stopped once, will produce five or six growths which develop into flower spikes. Overpotting should be avoided, five-inch pots being quite large enough to support strong, single specimens; should larger specimens be desired for special purposes, two or three plants may be placed in a six-inch pot. A mixture of two-parts good fibrous loam, one part decayed manure, with a sprinkling of coarse sand and a little bone-meal added, makes a suitable compost, and firm potting should be practised. If grown in a cold pit until the end of September, the plants will have made good foundations for subsequent flowering, and should then be transferred to a light house of intermediate temperature, where a free circulation of air and a fair amount of atmospheric moisture will maintain sturdy growth. The season of display may be lengthened somewhat by giving a number of the plants rather warmer conditions and thus accelerating the development of the flower spikes, but they should never be subjected to a very hot and humid atmosphere. *A. W.*

ARISTEA CORYMBOSA.

This interesting Irid, of shrubby and tufted growth, is an admirable plant for the cool greenhouse, delighting in a light, airy position and a peaty soil. The erect stems are clothed with small, glaucous-green, Iris-like leaves and, in winter, the corymbs of bright blue flowers will provide an interesting and attractive feature; there is, I believe, a variety with charmingly variegated foliage, of decidedly cheerful appearance.

Propagation of Aristea corymbosa may be effected by seeds sown in spring, by division of the plant, or by removing and growing on the sucker-like offsets.

A. corymbosa was at one time commonly known as Witsenia corymbosa; it was introduced from South Africa in 1803; there are several other species of value.

Aristeas are very ornamental when grown in pans, with a little charcoal added to the peat, or they may be planted in a border in the cool house. *R. E. A.*

ERYNGIUMS.

There are, in all, over one hundred species of Eryngium, but comparatively few of them are worthy of garden culture. However, among those that claim this distinction are some which rank among the handsomest of border plants. In the first place, the Eryngiums are divided into two classes, so distinct in their foliage that it is only in their blooms that the affinity can be traced. The group plant-lovers in general are most familiar with is that in which the upper foliage is divided and, in most instances, furnished with striking steely-blue colouring, and in which, also, the upper portions of the stems, and the prominent involucres are bedecked with similar brightness. The second group, the majority of whose members are only half-hardy, coming as they do from southern America, is what is generally termed the Pandanus section, the numerous species under this heading being distinguished by their long, undivided, but spiny-margined leaves of a subtropical appearance, and useful for producing such effect, but otherwise of comparatively little value for English gardens. Of them, E. pandanifolius is probably the most useful, and possibly the hardiest, and this may be employed in much the same manner as the Pampas, for it forms huge clumps of long, slender leaves, four feet or so in length, with spiny-toothed margins and tinged with a glaucous hue. But whereas the Pampas produces a handsome inflorescence, that of E. pandanifolius is, conversely, just as unattractive, consisting of a large panicle of small, green, rounded heads of flowers; however, for large spaces and as a specimen plant, E. pandanifolius has its uses. Other members of the group which enjoy a certain amount of popularity are E. agavifolium, with stout, long, coarsely spinose-serrated leaves and large, Teasle-like flower heads; E. aquaticum, E. eburneum, E. bromeliaefolium, E. Lassauxii and E. Serra, the last-named forming a large rosette of broadly sword-shaped leaves, up to about two feet long and with saw-like margins.

But it is with the other section that gardeners are chiefly concerned, for among its members are such handsome subjects as E. alpinum, E. giganteum, E. amethystinum and E. tripartitum, to mention but a few by way of introduction. These are all comparatively easily grown herbaceous plants, flourishing in deep, loamy and well-drained soil, hardy, and in most instances enjoying full exposure to sun, while, like many other fleshy-rooted subjects, they may be increased fairly successfully by root cuttings, or they may be raised from seeds sown either in autumn or early spring, the plants, if grown on in nursery beds, flowering when two years old, although if planted early and given generous treatment, some of them, such as the richly coloured E. tripartitum, will provide a bright display in the autumn of the same year.

E. alpinum, one of the handsomest of the species, is not so common as some of the others, E. amethystinum often arriving under its name, although from this latter species it is quite distinct. It comes from the alpine meadows of Switzerland where, although not rare, it is rather local in its distribution, and it seems to prefer slight shade in cultivation. Its dominant colouring is bright, steely-blue, the upper, branched portions of the flower stem; the finely and deeply-toothed, palmately-lobed, cauline leaves; the large and soft-textured involucre bracts with finely-cut, feathered margins; and the large flower-heads themselves, all being enveloped in this beautiful colour, and presenting in July and August a picture of striking beauty, being borne above a radiating cluster of long-petioled, deeply cordate and finely serrated, rich green basal leaves. Such is E. alpinum, one of the handsomest plants of the Swiss mountains.

And then, the Caucasus has given us E. giganteum, the Elves' Bones, so named on account of the silvery-whiteness and somewhat bleached appearance of its upper parts. This species attains a height of three to four feet, and, when cut, is much prized for winter decoration, a purpose for which this group of Eryngos is specially adapted. It is the giant of the section, the stout stem being clothed with shiny and deeply-lobed leaves and branching dichotomously in the upper part, to bear, terminately, large heads of flowers, each encircled with an involucre of eight or nine large, finely-cut leaves.

E. maritimum, our native Sea Holly, is by no means to be despised as a claimant for a place in the border or wild garden, for its metallic-grey leaves and flowers, borne freely on much-branched stems of one-and-a-half foot or so in height, during the latter part of summer, are often much admired; while E. planum, with erect stems to a height of three feet; ovoid or globular flower heads; narrow, rigid and spiny involucre leaves, and deeply divided, clasping leaves, all richly coloured with blue, is also worthy of a place.

As stated previously, E. tripartitum, considered to be of hybrid origin, ranks among the most beautiful of the Eryngiums. It is of different habit to the stronger-growing sorts, for the small, rich metallic-blue flowers, vivid in the intensity of their colouring, are borne in a mass of densely-branched, slender but stiff stems of the same colouring, the whole being up to about two feet high.

E. Spinalba is rather uncommon, but strikingly handsome. The lower part of its stem is whitish-green, while the upper portion, together with the ovoid-cylindrical flower heads, and the rigid, spiny involucre leaves, are steely-blue. This is another species from the European Alps. E. amethystinum is well worth its place in the garden, for it grows to a height of about two feet, and is of rather loose and open habit, while the colouring of its stems, upper leaves and flowers is rich amethystine-blue, sometimes inclined to be bleached. E. dichotomum is also desirable, its two-feet stems, globose flower heads and bracts being glaucous-blue in colour.

There are several Eryngiums of hybrid origin, notably E. Oliverianum, a strong-growing sort and one of the handsomest, with spreading involucres and flower heads of rich violet-blue. E. hybridum is a free-flowering sort with metallic-blue colouring, two attractive varieties of it being Jewel and Violetta, the former bright blue, and the latter a distinct shade of violet-purple; E. Zabelii is a lovely hybrid of amethyst colouring.

The above is merely a selection of what are possibly the finest of these beautiful, late summer flowering plants for the herbaceous border, or for grouping in sunny portions of the wild garden, where they will sometimes seed themselves and naturalise to a greater or lesser degree, but there are two species, namely, E. prostratum and the rare E. glaciale, which are specially desirable for the rock garden. E. prostratum is described by the late Reginald Farrer as a "bog plant" from Texas which, if planted in moist situations, "should make a running carpet, rooting as it goes, along all its ground-hugging branches." But that it would survive such conditions in this country is doubtful. I grew it (in ignorance) in the hottest position available, and fairly dry at the roots, and there it flowered abundantly, and formed a close, silvery-blue mass. In the winter it had a pane of glass to protect it, but it did not survive—possibly a moist place would have been better for it! E. glaciale is seldom offered; it inhabits hot, dry places at high elevations, in southern Europe, and there forms spiny tufts of silvery-grey, tinged with blue. It would appear to be a very charming subject, and in cultivation would probably require moraine treatment. *M. W.*

GARDEN CRINUMS.

Among the hundred or more species of Crinum, and the many hybrids which have been raised, there are very few that can be called permanent garden plants in the south of England. We live on the edge of the climatological area in which many of these plants flourish, and in favourable years quite a number will do well in our southern gardens. But, in our average summers the growing period is too short for them to increase in size and strength, and what we witness is a gradual exhaustion of the initial energy possessed by the bulbs when first planted, and their ultimate death. But there are some kinds that have become established here and do well. In the following notes I have omitted all the doubtful kinds and have dealt only with those of proved ability to thrive in our climate.

In the open ground, C. longifolium (capense) is hardy in most places, but it is doubtful whether it is worth growing. There are some finer types allied to C. longifolium which are worth growing —such as C. lineare* and C. variabile*—but these are not so hardy as the type of C. longiflorum. C. Powellii (A) was considered hardy, and is hardy in places near the south coast, but Messrs. Williams, about forty years ago, lost an entire bed of C. Powellii through an intense frost. Their gardens were near Lord's Cricket Ground.

Planted close up to a wall and covered with a foot of dry material in winter, the following are successful:—

C. Powellii (A) all varieties. Flowers July to September.

C. yemense (B). Flowers before any other Crinum. White, fragrant.

C. pratense (?) (C). Beautiful and very fragrant white flowers with red keel. Fugaceous. Flowers in June and July. Not the C. pratense of Baker.

C. Tubergeni* (C). A fine and fairly hardy plant, but does not do well with me.

---

* Signifies that such plants are difficult to obtain.

(A) Signifies kinds that flower regularly in most places in the South of England.

(B) Signifies kinds that flower occasionally in most places in the South of England.

(C) Signifies kinds that flower in some places in the South of England.

Crindonna memoria Corsii (A). Most floriferous and beautiful. Flowers pink.

All these Crinums prefer a heated wall.

In a bed in a cold house, and mulched against frost, there are many Crinums that can be successfully grown, but thrips must be guarded against. Most deciduous kinds do well so grown, but not the evergreen kinds.

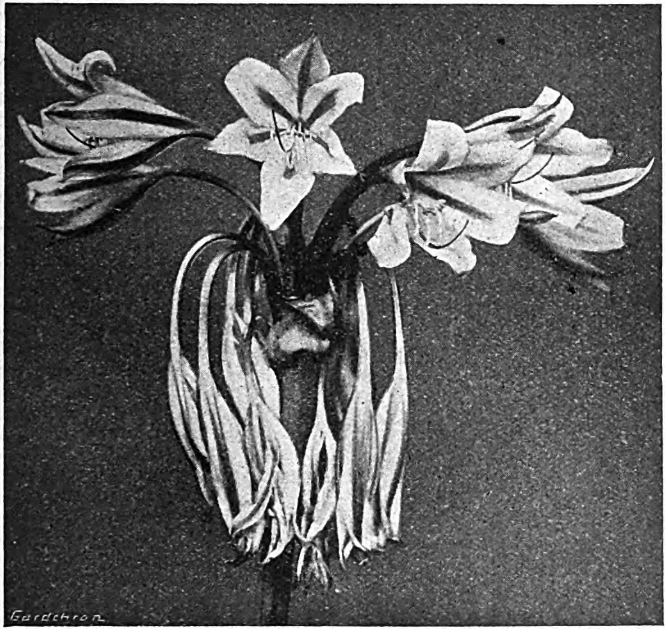

FIG. 108.—CRINUM SP. FROM THE SUDAN.
Flowers fully open.

In a temperate house the following do well in pots:—

C. fimbriatum. Very floriferous and beautiful. Will do well in a pot of moderate size. Pink and white.

C. giganteum. Flowers in late autumn and winter. Floriferous. Pure white.

C. scabrum. The small-leaved kinds, like those of Jamaica, are most beautiful, but demand large pots and careful culture. White, striped carmine.

C. odorum.* This species from southern Brazil is second to none in beauty and grows freely. White, striped pink.

C. Moorei. Some varieties are worth growing, especially the original importation figured in *Bot. Mag.*, t. 6,113*; also var. Schmidtii, figured in *Regel's Gartenflora*, t. 1,072, but many more recent importations are poor things.

Crindonna memoria Corsii.

Anyone who can spare sufficient room to plant out Crinums in a warm house has a wide choice. I used to grow C. amabile (C. augustum ?) thus, and with great success. Its flowers are of astonishing beauty and fragrance.

With the exception of kinds in general cultivation, it is now difficult to obtain large bulbs ready to flower shortly after planting. Very many species have disappeared from catalogues since the war, and I can give no help in suggesting where such bulbs may be obtained.

As our outside Crinums, such as C. Powellii, have long, straggling leaves, they should be grown in a thickly-planted row against a wall. The mass of foliage then produced holds itself up somewhat, and holds up the flowering stems, too, against winds and rains. No attempt should be made to plant a single bulb as a specimen in an isolated place. Crindonna has shorter foliage and is more desirable on this account.

Of the great number of hybrid Crinums raised in English gardens, very few indeed have survived for any number of years. Some were vigorous enough for a few years, but then disappeared. I have raised quite a number in my garden, and some of great beauty, but none of them survived the stress of the war years. C. Powellii is an outstanding exception, and is now to be found all over the temperate regions of the world.

Practically all the Crinums are valuable as cut flowers for large vases. C. Powellii is now becoming a market flower for such purpose. The umbels will last about a week after cutting. Some sorts are rather fugaceous. On the other hand, C. Moorei, C. giganteum and many others, only expand fully after sunset and look at their best for evening decoration. Some of the tropical Crinums are exceedingly fragrant, and most kinds are scented to some degree.

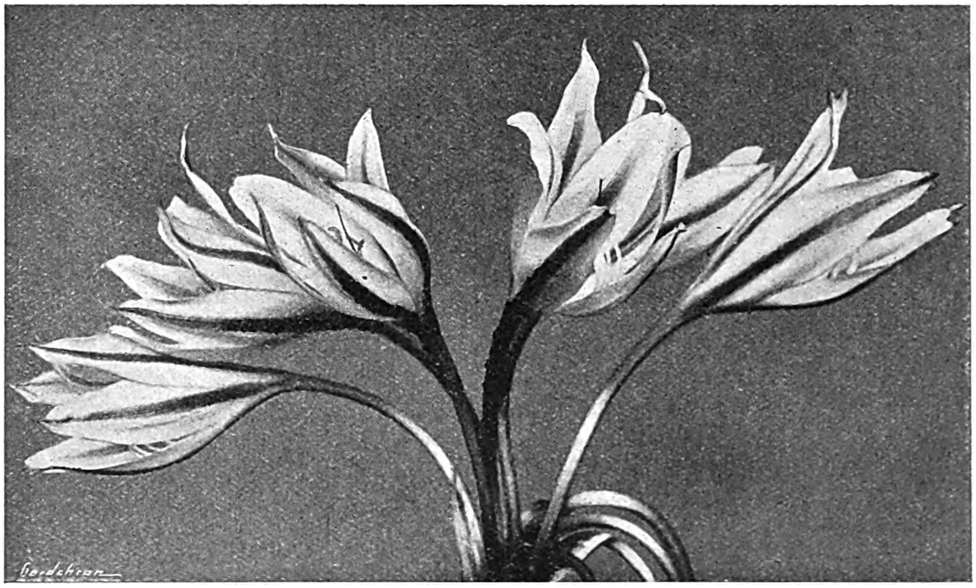

FIG. 109.—CRINUM SP. FROM THE SUDAN.
Flowers partly open.

Sub-genus Codonocrinum.

This sub-genus is distinguished by Baker on account of a funnel-shaped perianth, a permanently-curved tube, and contiguous filaments. He admitted twenty-seven species in this sub-genus, and since his day many more specific names have been added.

In early days, geographical distribution was relied on, and botanists have tried to maintain this line of division between species. But the trouble is that over a wide belt of tropical country going east and west the same groups of species, in endless variety, persist over the whole of the zone. We find the one- to three-flowered C. scabrum type of the west coast merging insensibly into the eight-flowered typical C. scabrum, and that again into the twenty-flowered forms classed under C. zeylanicum.

The problem of specific rank among these striped African Codonocrinums has puzzled every botanist, and remains unsolved to the present day. It is practically certain that the Crinum here figured (Fig. 108 and 109) belongs to this section of Codonocrinum.

Crinum Species from Sudan.

The pair of photographs sent herewith (Figs. 108 and 109) are of a plant from the Sudan which is either a new species belonging to the above group, or is an especially beautiful form of some member of this group of species and varieties.

It is remarkably floriferous, carrying five or six scapes in succession at midsummer, each scape bearing about twenty flowers of great size and opening in succession. These are white, brilliantly keeled on both sides with carmine. It has a deciduous, pyriform bulb about five to six inches in diameter, foliating in spring, and carrying seeds freely.

All the varieties of C. scabrum which I have grown, or seen, carry not more than eight flowers to the umbel, and never throw up more than two, or rarely three, scapes during the growing period. But the bigeneric hybrid, Crindonna memoria Corsii produces so many as four or five scapes in one season.

There are two garden divisions into which C. scabrum may be roughly divided: (1) The foliose African varieties, whose flowers are neither very large nor very beautiful; and (2) the less foliose forms, some of which are American, and which carry the most beautiful flowers in the genus. The best form I have ever seen I gathered in Jamaican gardens, but it is doubtfully indigenous there, as the slaves from Africa used to plant this species wherever they went, considering the juice of the bulb to be a remedy against a contagious disease.

In a short time it may be possible to determine the affinity of the fine Sudan plant figured on this page. *A. Worsley, Isleworth.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

CHILE AND THE ANDES.*

No. VIII.

FROM Valparaiso we got occasional glimpses of the Andes, pale and dim and enormously distant, and it made us restless to get away from town to the mountains. But it was mid-September, and still too early to be pushing up into the Andes. We found, however, plenty of useful collecting to be done in the immediate neighbourhood, and by making short raids into the country. We went one day to Villa Altamana, an hour or two by train, a small, dull, tidy town, and from there walked up into the hills.

From the train we saw a few scattered specimens, on the hillsides, of the native Chilian Palm, Jubaea spectabilis, which has become extremely scarce. A very splendid Palm it is, running up to fifty feet or sixty feet, with a smooth, silvery, ash-grey trunk like elephant hide, and a noble, plumose head of rather glaucous blue-green. Darwin did not admire Jubaea spectabilis, although he wrote an interesting account of it. In his day, it grew in countless thousands, but the Chilians make a sort of honey, Miel de Pelma, by cutting down the trees and draining the sap from the trunks. This Palm honey is, or was, a great delicacy, but through its manufacture the Jubaea became almost exterminated. There still exist groves of it at Ocoa (Fig. 112), and occasional, scattered, isolated specimens are to be seen here and there such as those on the way to Villa Altamana, while in a small way it is raised in one or two Chilian Nurseries for planting in gardens and public parks. But the vast Jubaea forests of Darwin's day have gone, wiped out for the sake of the Palm honey. Vanished sources of supply, however, seem to have made no difference to the actual supply. Miel de Palma is still a popular delicacy, sold in tins and served in restaurants, with a picture of Jubaea on the label to help out one's imagination. It is probable that more of this honey is produced now than in the days when there were Palms to produce it from. What a pity they did not think of this before, and save the Palms! Jubaea spectabilis is grown occasionally on the Riviera, and is hardy in favoured districts in this country, such as the Isle of Wight, etc.

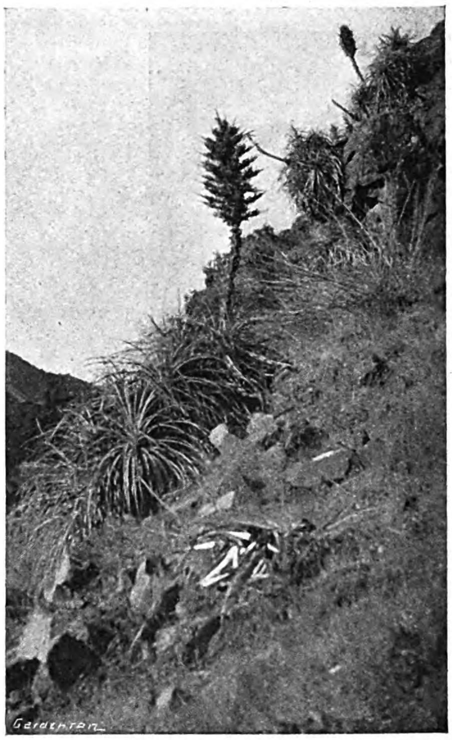

FIG. 110.—PUYAS ON A CHILE HILLSIDE.

At Villa Altamana I found Acacia cavernea (?), a Mimosa growing with the picturesque habit of a British Blackthorn. The trees were still leafless, but the terrible double thorns, three and four inches long, with which they were armed, gleamed white in the sunshine and made them look extraordinarily like Blackthorns in full blossom (Fig. 111). Later, I saw Acacia cavernea (? Cavenia) in flower, and thought it an attractive tree. It has the typical pinnate leaf of a small, neat Mimosa, and the little velvet bobbles as flowers, but instead of the usual canary-yellow they are a rich treacly-gold, and heavy with a peculiarly heady and rather worldly fragrance. Not so the roots, however, for they give off one of the most offensive stenches of any plant I know. I brought home a few seeds, and recently, when half-a-dozen seedlings, a couple of inches high, were being potted up, very grave complaints were made to the potter by folk who were working four or five yards away in the same shed. I would hardly have thought this possible had I not knocked out one of the tiny seedlings to give myself a practical demonstration of the vileness of its minute roots. It is possible that this plant may prove hardy in one or two of the districts in England and the west of Scotland, where Camellias and Mimosas flourish in the open, and it will, I think, make a good pot plant for the cool greenhouse.

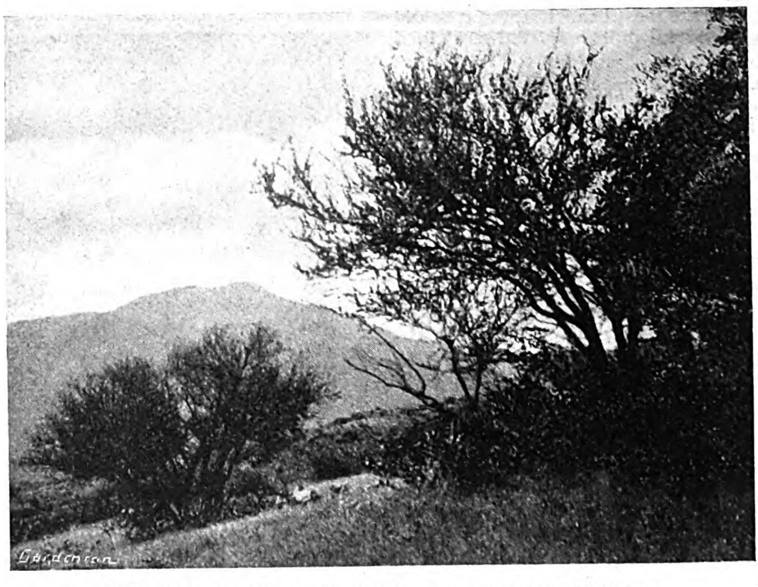

FIG. 111.—ACACIA CAVERNEA (?) NEAR VALPARAISO.

Puya chilensis grew in great abundance on these hills, and formed great specimens fifteen feet and twenty feet across, like gigantic, sprawling colonies of Yucca (Fig. 110), with elongated, thorny leaves. We found vast numbers of these Puyas which had been burnt out, and were told that they catch fire spontaneously from the sun's heat. Many were burning on the hills while we were there, and I found that a single match applied to the tip of a dead Puya leaf, will, in five minutes, produce a roaring, blazing furnace of unbelievable and almost terrifying intensity. There is always enough old, dead dry leafage to consume the whole of the green, leafy plant, and, fortunately, the plants grew isolated, so that there was no fear of setting the whole countryside in a blaze. Matches are reasonably cheap in Villa Altamana, and Puyas must be the worst possible grazing, and for these reasons I do not attach much importance to the spontaneous combustion theory.

In the cooler, shadier folds of these hills, the lovely Tecophilaea violaeflora was very abundant. It grew on little swards of brilliant emerald-green, annual herbage, and here for the first time I realised the plant's extraordinary beauty. The brilliance and intensity of its pure blue gave an illusion almost of Gentiana verna at its best in the Alps, although the illusion was instantly dispelled when one looked up and saw around one groves of enormous Cacti fifteen and twenty feet high.

On this same expedition, we saw Tropaeolum tricolor for the first time, trailing its lovely flowers with incomparable grace. It grows from a corm, like a Cyclamen corm, and trails over bushes just as its cousin the Flame Flower (Tropaeolum speciosum) trails, with the same dainty leaves of fresh lettuce-green, but the flowers of T. tricolor are smaller and neater, little, curved, elfin caps of a soft brilliant scarlet, changing suddenly at the mouth to purplish-black, with a touch of yellow within, or in some forms a touch of emerald-green. They are strung in tapered flights, minute green buds at the tip of the flight, and so ranging back, larger and larger, and more fully coloured, until the last and largest are intensely brilliant. I came upon T. tricolor many times in many parts of Chile, and every time I saw it I marvelled afresh at the enchanting beauty and brilliance of its blossoms. The plant is, of course, well-known in cultivation, although one seldom meets it nowadays. Its half-hardiness, has, I am afraid, been long established, but I collected many seeds, so I hope that this lovely thing may be seen more often in cool greenhouses. *Clarence Elliott.*

---

* Previous articles on Mr. Clarence Elliott's expedition were published in our issues of November 12 and 26, December 10 and 24, Vol. LXXXII; January 7 and 28, Vol. LXXXIII; and July 28, Vol. LXXXIV.

PLANT HISTORY IN NOMENCLATURE.

(*Continued from p.* 204).

The Story of the Citron.

While dealing with the Citron and Lemon we found ourselves faced with certain questions relating to the Semitic languages, and the usages of the Hebrews in ancient and modern times (see p. 204). In attempting an answer to those questions we will begin by citing a passage from the Hebrew writings, which forms an excellent starting point for our investigations.

"Ye shall take you on the first day boughs (margin 'fruit') of goodly trees, branches of Palm trees, and the boughs of thick trees, and Willows of the brook" (*Leviticus*, xxiii, 40).

A volume might be filled with the learned notes which have been written on these words; but our special concern is with the phrase which was formerly translated "boughs of goodly trees," but now reads in the Revised Version, "fruit of goodly trees." Much confusion has been introduced by writers who do not keep in mind the fact that many of the fruits which are well-known to-day were unknown to the ancients. The Hebrews certainly knew the Fig and Grape, the Pomegranate and Date, but when we come to the Orange, Lemon and Citron it is a different proposition. Yet, in some way or other the Citron, of which we wrote in our last paper, has come to be most intimately associated with this phrase, and with the observance of the Feast of Tabernacles by the Jews. Can we trace the Citron back to pre-Christian times? Much depends on the meaning we place upon the words in use among the Semitic races. There are many references in early writings to the Apple, but that word was employed very vaguely, and covered a variety of fruits. Golden Apples may have been any kind of fruit with a rich colour, and the term certainly was not always used of, or restricted to, either Apples or Oranges.

One of our earliest and best authorities is Josephus, and we therefore turn to him for help. Here is an interesting passage from the Antiquities (xiii, 13, 5), referring, perhaps, to the year 95 B.C. "As to Alexander, his own people were seditious against him; for at a festival which was then celebrated, when he stood upon the altar, and was going to sacrifice, the nation rose upon him and pelted him with Citrons."* These fruits, Josephus tells us, the people were then carrying, because the law required that at this festival everyone should be provided with branches of Palm-tree and Citron-tree. Chiefly on the strength of this passage it has been affirmed that the Citron, whatever may be said respecting the Lemon and Orange, its nearest relations, was certainly known to the Jews several generations before the time of Christ. Moreover, the *Targum* on the passage from Leviticus explains the phrase "fruit of goodly trees" by words which may be translated "the fruit of the Citron trees."

Here, however, a new difficulty arises, for while Josephus uses the Greek word "Citron," the *Targum* employs a Hebrew or Aramaic word of a totally different kind, and the question is—Can we show that the Greek Citron tree (κιτςεα) and the tree represented by the Hebrew word, usually written *ethrog* in the English transliteration, are one and the same? The word *ethrog* is related to the Arabic, as we find it in the place-name Jebel-Atranjah, or the Citron Mountain, and leads us to suppose that the Jewish commentators used the popular Arabic name for the Citron when explaining the early usage. One of the Greek names for the Citron was Persian Apple, and this suggests that the western knowledge of the Citron was derived from the east. Since the Jews were intimately acquainted with Babylonia and the surrounding countries they undoubtedly became familiar with the fruit in very early times, as De Candolle and other authorities on cultivated fruits have pointed out. It was a native of Media, and was introduced into Palestine, where it soon became established. And in this connection it is of interest to be able to turn to the Jewish coinage, which bore representations of various objects having a religious or historical nature. Among these are some relics of the Asmoneans, and in particular the so-called Lulab coins. These are so named because they bear, among other things, representations of the Palm branch, or Lulab. They have been very carefully and critically examined, and are held by experts to be an attempt to put the plants of the Feast of Tabernacles in pictorial form. On one side of these coins a vessel containing three plants is represented, with a fruit on the left side of the basket. "The fruit and the three plants have been identified as those named in Leviticus xxiii, 40, the fruit of the goodly tree, branches of Palm trees, boughs of a thick-leaved tree, and Willows of the brook, generally called the *arba minim*, or the four kinds, viz., the *ethrog* (Citron), *lulab* (branches of the Palm tree), *hadassim* (Myrtle), and *arabhah* (Willow)." This agrees with what we find in the *Talmud*, where a bunch made up of Palm, Myrtle and Willow is ordered to be carried in the right hand, and a Citron, Orange or Lemon in the left. This usage, which persists to the present time, is not based on any Old Testament law, but shows how in the course of ages the Jews had been affected by their association with the surrounding races. We see clear evidence of the influence of Greek religious usages, such as prevailed at their harvest festivals and in the worship of Bacchus.

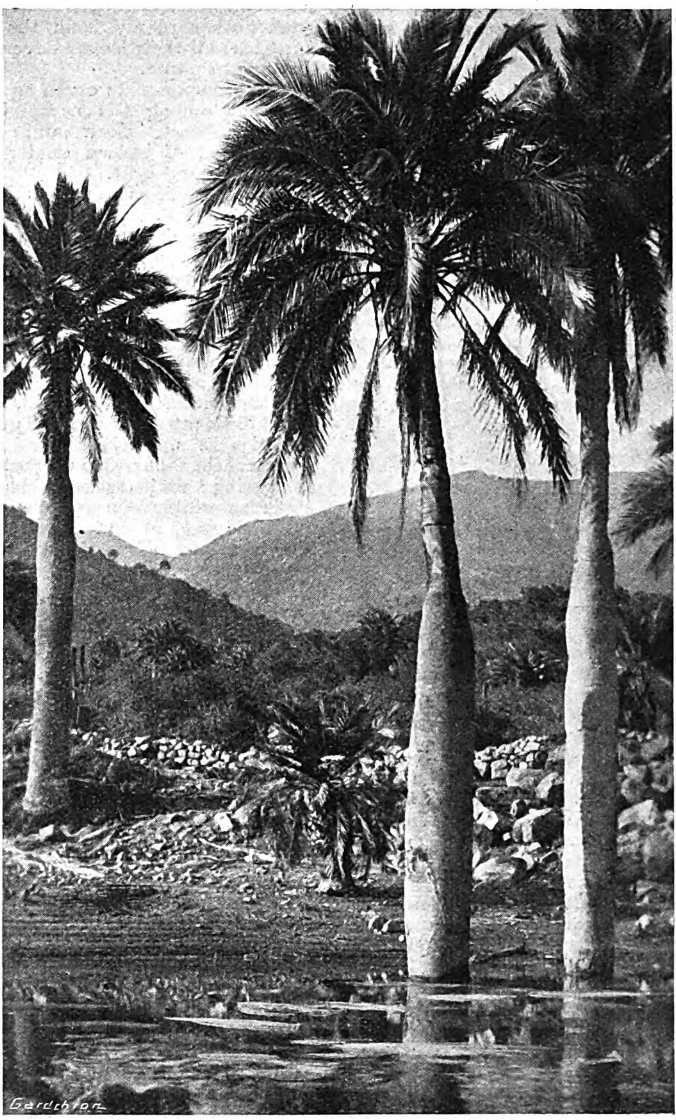

FIG. 112.—JUBAEA CHILENSIS AT OCOA, CHILE.

Recent research brings to light the fact that the Citron and other fruits were associated with worship in almost every eastern land. In India the Lemon is used emblematically perhaps in some phallic sense. If we go further afield we come across the fact that in China to-day the horned Citron or "Fat-shau kom," as the Cantonese term it, is carried by the Chinese in their hands on certain occasions, and is regularly placed as an offering on the Buddhist altars. For a valuable notice of this monstrous form of Citron we may refer to the issue of this journal for March 20, 1890, p. 385, with illustration.

It is further possible, we think, to show that the Citron was used in very ancient times by the Assyrians and Accadians, together with the Cedar or Fir-cone, and thus came to be known among the Hebrews. This being so, we shall be entitled to look for light on the origin of the name "Citron" in the Assyrian and early Semitic languages, while it may further be easy to discover how it is that the Latin and Greek words for the Citron and Cedar have in later years been confused. They were, doubtless, originally one and the same. As philologists have failed to find any satisfactory history of these words in the Aryan root-forms, Semitic scholars will readily admit that they may contain the three consonants which are characteristic of Hebrew, Arabic and allied tongues. Can we, then, find a Semitic root (or roots) with the consonants c-t-r, or k-d-r, which will give us Citron, Cedar, (κεδοσος), and the allied forms? And if so, can we find the same root in *ethrog*? The answer is in the affirmative.

Let us remember that the Citron, is in Chinese, the "Fragrant Fruit," and that it is used for scenting rooms, and producing a grateful perfume in sacrifices. Thus it is in a sense a substitute for incense. Now incense in Assyrian was *kutrinnu*, a word which is identical in form with Citron or κιτσον. And since Cedar wood entered into the manufacture of incense it is easy to see that this word is from the same root. Possibly the Cedar cone and the Citron fruit were interchangeable. In Hebrew, Arabic, Syriac and Aramaic the same word is found, and this under two forms. In one form it has the three consonants, k-t-r, c-d-r, or q-th-r, and in the other the initial letter is softened or reduced to a breathing or nasal, and so becomes e-th-r or a-t-r, with a variety of modifications in derivatives; and so we get *ethrog*, and the name of the Citron mountain, Atranjah.

---

* This story is related of other persons in the *Talmud* and elsewhere.

We thus arrive at these conclusions: The Citron has been known in the east from time immemorial. It is a Median fruit, and as such would bear a name which was significant of its fragrance. The root of this word is to be found in the old Semitic name for incense, and in the Hebrew and allied words. It survives in the word *ethrog* which means Citron in the *Talmud*, and in the Arabic name for the Citron mountain, and was taken up by the Greeks who adopted the name and adapted it to the genius of their language, handing it on to the Romans as Citron. But the Cedar bore the same name, the word dividing, as was so often the case, into two cognate forms, and from this followed the fact that in the Romance languages some derivatives are from Citron and others from Cedar, even the dictionaries until quite recently failing to trace the connection. I think that the word nectar may be traced to the same source, since it is without a satisfactory Aryan pedigree. *Hilderic Friend.*

(*To be continued*).

EFFECTS OF THE GREAT FROST IN SUSSEX.

This county, situate in the south-eastern corner of England, no part more than thirty miles from the sea, and favoured by sunshine, would appear to be an ideal home for many of the somewhat tender plants introduced from other climes. It must not be forgotten, however, that Sussex shares with Kent a close proximity to the continent, rendering it liable to the unmitigated severity of north-easterly winds, which bring very low temperatures from colder regions.

The most favoured part of the county is probably the southern side of the forest ridge, running east and west, beginning south of Tunbridge Wells and culminating in a peculiar V-shaped formation of low, wooded hills sheltering the well-known gardens of South Lodge, and Leonard's Lee, on the east side of Horsham. Several other noted gardens are situate either on the small spurs, or in the sheltered valleys (combes) at right angles to the ridge. Worthing is, of course, famed for the earliness of its produce and frost is, perhaps, less severe there than anywhere else in the county.

The coldest night was that of February 14, when 20° to 26° of frost were registered in various gardens in Sussex the following morning. It is still too early to decide the amount of damage suffered by the more tender trees and shrubs. Much is already apparent, and it must approximate closely to that of the winter of 1916 and 1917, or even of 1895 and 1896. In both previous cases the frost was prolonged and losses sustained were more probably due to the persistence of low temperatures than to severity of any one particular night. The recent frost has been notable, at least, in the south, for the absence of any depth of snow, and a considerable amount of sunshine.

Judging from many letters received and my own experience, the more tender Ericas, and especially E. Veitchii, have either been killed or injured. Large plants of E. australis, although not altered in outward appearance, have their bark on the older wood split into long shreds, easily removable by hand, the bare wood showing beneath. E. lusitanica and E. arborea do not appear to have been affected in this way, but some of the smaller branches half-an-inch in diameter, are splintered into six or more sections. E. vagans is injured in the same manner.

Regarding the Rhododendrons it is difficult to judge; the earlier buds on such varieties as R. Nobleanum have been destroyed, but most species and varieties are backward, the cold has retarded the sap, and buds have expanded but little, even so, embryo flowers are often injured by frost. This occurs sometimes in November, for blackened flowers may be found in December if a bud is cut through transversely, hence the imperfect trusses which appear later. Among seedling R. arboreum plants, six to eight feet in height, it is interesting to notice the different degrees of hardiness; some are unharmed, with leaves of a rich dark green, other plants from the same seed-pod, must lose all their leaves—even now they rattle like brown paper.

All correspondents agree as to the few losses apparent among the newer introductions by Messrs. Forest, Rock and Kingdon Ward. Only a few, of known tender character, have been killed outright.

Tender Conifers, such as Pinus patula, P. Montezumae, P. Torreyana, Cupressus lusitanica and C. cashmiriana, have in most cases been severely injured, although even these seem to have escaped in one of the warmest gardens. Abies religiosa, Lindera megalophylla, Maytenus Boaria and Lonicera nitida have shed their leaves profusely. Large plants of Leptospermum scoparium which came safely through the winter of 1916 and 1917 are badly damaged, and the withered leaves will, if the plants are not killed, probably drop. This species, and its varieties L. s. Nichollii, and L. s. Chapmanni, appear most vulnerable to frost when the plants are ageing; we lost several about eighteen years of age last winter, whereas younger plants escaped.

Eucalyptus, of which many species have of late been planted in Sussex, will, if not killed, require many years to recover. E. Muelleri, E. regnans, E. vernicosa, E. viminalis and E. cordata are among those injured. Drimys Winteri, D. aromatica and D. colorata, all show damage, but this, it is hoped, is more apparent than real. Nursery beds of E. cordifolia, slightly protected, are severely injured or killed; older plants and specimens are browned, Eucryphia Nymansay (E. cordifolia × E. pinnatifolia) has sustained no injury, even the buds at the ends of immature shoots are undamaged, a few of the older leaves are browned, but this appears to be the case with all evergreens, Box edgings and Laurel, being sadly discoloured.

Hydrangeas, of the hortensia section, have most of their terminal buds destroyed; the axillary ones sometimes produce flowers, but they are never so fine. Others, including H. Sargentiana, appear uninjured. Hoheria populnea, twenty feet in height, Rhaphithamnus cyanocarpus, Olearia Forsteriana, O. nitida and Mitraria coccinea suffered cruelly last winter, and it is doubtful if they will survive the second ordeal.

The more deciduous Nothofagus, such as N. obliqua, N. procera and N. antarctica, are apparently uninjured; N. cliffortioides, N. Solanderi and N. fusca are doubtful, but the foliage on N. Dombeyi, N. Menziesii and N. betulioides is certainly destroyed and possibly the trees as well. Berberidopsis corallina, Lapageria rosea and its variety alba, Kadsura chinensis, Euonymus fimbriata, Osmanthus Fortunei, O. Forrestii, Myrsine africana, as well as the Tricuspidarias, have a miserable, browned appearance, and will most likely need the free use of the knife in the near future.

Of the earlier plants sent home by Comber (Andean Expedition) a number were planted in an open field, and although the upper portion is sere and browned as a herbaceous plant would be, the lower portion is full of life and vigour; this does not include the Berberis, Escallonias, and Azaras, etc., sent home in the second year. They have not yet been planted outside.

A long list might be added of those plants which have proved hardier than their reputation, but as appearances are deceptive, and never more so than after a frost, that may be left until later. *J. Comber, Nymans Gardens, Handcross.*

PLANTS INJURED BY COLD AT LA MORTOLA.

On several occasions we have published lists of plants flowering in the open at Mr. Cecil Hanbury's garden at La Mortola, Ventimiglia. Now, unfortunately, the record is not so pleasing, indeed, it is one of damage done by 14° of frost and six inches of snow on February 20 last. The list is from Mr. S. Braggins, the Superintendent of the gardens, who made it out in March and states that all the plants listed have suffered from the severely cold weather, and those asterisked are very much damaged and in some cases killed.

*Acanthus arboreus, Achania mollis, *Adenium obesum, Acokanthera spectabilis, Agave albicans, *A. attenuata, A. caespitosa, A. flaccifolia, A. spectabilis and A. Willdingii; Agathaea petiolata, *Ageratum mexicanum, Aloe abyssinica, A. aculeata, A. affinis, A. arborescens var. frutescens, A. a. var. natalensis, A. a. var. Milleri, A. Brunnethaleri, A. Candelabrum, A. ciliaris, A. cyanea, A. Dyeri, A. globuligemma, A. grandidentata, A. Greatheadii, A. Hanburyana, A. Johnstonii, A. lateritia, A. latifolia, A. pendens, A. percrassa, A. Pienardii, A. pluridens, A. mortolensis, A. rubroviolacea, A. Salm-Dyckiana, A. sessiliflora, A. Simii, A. spinosissima, A. spec. from Kew, A. Straussii, A. succotrina, A. s. var. saxigena, A. wickensis, A. Winteriana and A. Thraskii; *Anona Cherimolia, Araujia megapotamica, Argyreia speciosa, Arundo Donax, Ardisia latifolia, Asparagus aphyllus and A. plumosus.

*Bauhinia grandiflora, *Begonia fagifolia, B. macrophylla, *B. manicata, *B. miniata, *B. semperflorens, *B. Rex and *B. weltoniensis; *Bignonia venusta, Bougainvillea glabra, B. Sanderiana, B. spectabilis and B. s. var. lateritia; *Bouvardia coccinea, *Bryophyllum crenatum, Buddleia madagascariensis and Bulbine aloides.

Caesalpinia tinctoria, Calycanthus occidentalis, *Canarina Campanula, *Cantua buxifolia, *Caralluma sp., *Casimiroa edulis, Cedrela sinensis, Celtis caucasica, *Cereus Quelichii, *C. triangularis and *C. urbanianus; Ceropegia Woodii, Cestrum aurantiacum, C. lanatum, C. nocturnum and C. suberosum; Chimonanthus praecox, Chlorophytum elatum, *Cineraria stellata, Citrus japonica, C. Aurantium, *C. Medica Cedrato di Firenze, C. m. var. multiforme, C. m. var. Limone di Catalogna and C. nobilis; Clivia miniata, Colocasia antiquorum, *Convolvulus floridus, Cordia Francisci and C. serratifolia; Cotyledon macrantha and C. orbiculare; Crassula lactea, C. portulacea, C. rosularis and C. rubicunda; Cussonia triptera, *Cyperus alternifolius and *C. Papyrus.

Dahlia Maximiliana, Datura arborescens, D. chlorantha and D. sanguinea; Dianthus Caryophyllus, Diplopappus fruticulosus, Dimorphotheca Ecklonis, *Dombeya Cayeuxii and D. Wallichii, *Dracaena Draco, Dunalia cyanea, Duranta Plumieri and D. inermis.

Echeveria gibbiflora, E. g. var. metallica, E. g. var. caruneulata, E. leucotricha and E. multicaulis; Echium callithyrsum, E. fastousum and E. formosum; Erythrina Crista-galli and E. insignis; Eucalyptus Globulus, Euphorbia abyssinica, E. aphylla, E. balsamifera, E. Bojeri, E. Erythraeae, E. grandidens, E. Hermentiana, E. mauritanica, E. parciramulosa, E. Schimperi, E. tetragona and E. Tirucalli.

Ferdinanda eminens, *Ficus comosa, *F. laevigata, *F. macrophylla, *F. religiosa and *F. scabrifolia; *Fuchsia arborescens and *F. triphylla; *Furcraea gigantea and F. Selloa.

*Grevillea Banksii, G. robusta and *G. Thelemanniana; and Gynura aurantiaca.

*Hebeclinium ianthinum and *H. macrophyllum; *Hardenbergia Comptoniana, Hedychium Gardnerianum and H. carneum; *Heliotropium peruvianum, *Hexacentris coccinea, Hibiscus heterophyllum, H. Rosa-sinensis and H. splendens.

Iochroma coccinea, I. grandiflora and I. lanceolatum.

Jacaranda ovalifolia, *Jasminum nitidum and J. officinalis.

*Kalanchoe marmorata and K. somaliensis; Kleinia amanensis, *K. Galpinii, and *K. neriifolia.

*Lavandula abrotanoides and L. dentata; Lantana Camara and L. lilacina, *Lippia citriodora, Lotus peliorrhynchus, and Lycium cestroides.

*Mackaya bella, Mesembryanthemum aequilaterale, M. deltoides, M. echinatum, M. pulchellum, M. rubricaule and M. serrulatum; *Monstera deliciosa, *Montanoa bipinnatifida, *M. tomentosa, and M. Wercklei; Muehlenbechia complexa and M. platyclada; Murraya exotica, Musa Basjoo, M. Ensete and *M. paradisiaca.

Odina caffra, Odontospermum sericeum, Olmediella Betschleriana, Opuntia megacantha variegata and O. Turpinii diademata; Oreopanax dactylifolium, and Oxalis cernua.

Pavonia spinifex, Paspalum dilatatum, Pelargonium athamanthoides, P. gibbosum, P. hybridum, P. inquinans, P. heterogamum, P. lateripes, P. peltatum, P. Radula, P. roseum, P. tomentosum and P. zonale; Periploca graeca, Persea gratissima, Phytolacca dioica, Pilea macrophylla, Plumbago capensis, *Pithecootenium buccinatorium, and *P. muricatum; Podranea Ricasoliana, Pontederia cordata, *Portulacaria afra, Pouteria laurifolia, *Primula sinensis, Psidium Araca, and Pteris longifolia.

*Reinwardtia trigyna, Reseda odorata, Rhapis flagelliformis, Richardia africana, Rosa Banksiae and *Royena pubescens.

*Salvia albo-caerulea, *S. amarissima, S. angustifolia, S. discolor, S. elegans, *S. Heerii, *S. involucrata, *S. leonuroides, S. mentiens and *S. Sessei; Schotia latifolia, Schutia buxifolia, *Satureia viminea, Sedum linearis, Sempervivum arboreum, S. Berthelotianum, S. canariense, S. chlorochrysum, S. ciliatum, S. cuneatum, S. decorum, S. giganteum, S. glutinosum, S. Haworthii, S. holochrysum, S. urbicum, S. velutinum and S. Webbii; Senecio angulatus, *S. grandifolius, *S. hadiensis, *S. Heritieri and S. Petasitis; Solanum aviculare, S. acanthocarpum, S. auriculatum, S. cyananthus and S. Warszewiczii; Sonchus Jacquinii, Statice brassicaefolia, S. fruticans and S. macrophylla; Stapelia Hanburyana and S. variegata; *Stenolobium alatum and *S. Stans; Strelitzia Augusta, and *Streptosolen Jamesonii.

*Tacsonia manicata, *Tecomaria capensis, Tetrapanax papyriferum, Toona ciliata, Tournefortia Messerschmidia, and *Tropaeolum majus.

Vitis quinquefolia and *V. Voineriana.

*Wigandia caracasana and *W. urens.

Zebrina pendula and Z. tricolor.

TREES AND SHRUBS.

DAVIDIAS FROM CUTTINGS.

THE article by Mr. Grove on Davidia involucrata (p. 182) proved of great interest to me, as, for several years I have been trying to propagate Davidias from cuttings, with the following results.

In the summer of 1925 I raised one plant of Davidia Vilmoriniana from a cutting made about three inches long, of thin wood, taken with a slight heel of older wood, from a seedling plant which was scarcely one year old. The plant in question was forming a "double leader," and the shoot removed—although by no means a promising cutting—was inserted in pure sand in a propagating frame having a temperature of about 65°, where it produced roots in late summer and was potted up, and grown on under glass until the spring of 1926. It was then planted in a nursery bed with other Davidias which had been raised from seeds sown in October, 1924. On measuring the plants to-day (March 9, 1929), I find the one raised from the cutting inserted in 1925 is two feet six inches high, while a seedling is four feet three inches. This, however, is not quite a fair comparison, for, as indicated above, the shoot inserted was not in the first place an ideal cutting.

On September 3, 1928, I had occasion to prune some four-year-old seedlings of Davidia Vilmoriniana, and instead of throwing away the prunings, I carefully severed them with a slight heel of older wood and inserted them in pure sand in a warm propagating frame having a bottom temperature of nearly 70°. On examination in the last week in September, 1928, four of these cuttings were found to be rooted, and have since become established in pots.

Although two of the rooted cuttings were so much as eight inches in length (Fig. 113) when they were inserted (that is about three or four inches above what is considered normal), I did not shorten them, and shall watch with interest the amount of growth they make in a period corresponding to that of the plant raised in 1925.

Regarding Davidia involucrata, on August 28, 1928, I inserted three cuttings taken from two small plants which were raised from layers. The cuttings were of the current year's growth, being thin shoots not quite three inches long, and made with a slight heel of older wood. These were inserted under the same conditions described for D. Vilmoriniana; and one produced roots and was potted on October 20, 1928, and at the time of writing it is commencing to make new growth.

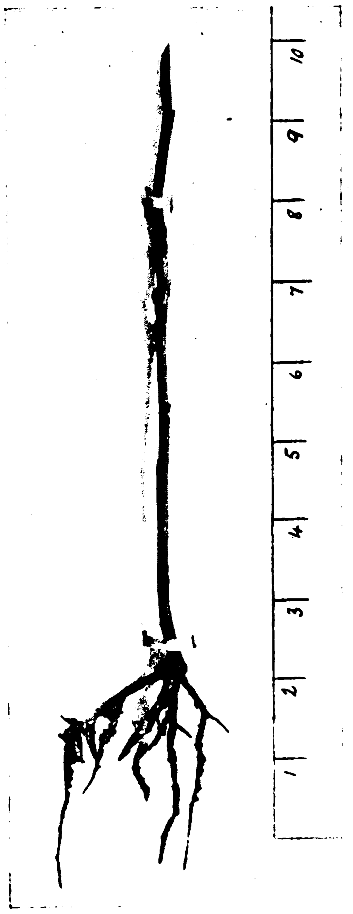

FIG. 113.—A ROOTED CUTTING OF DAVIDIA VILMORINIANA.

Inserted Sept. 3, 1928; photographed March, 1929.

Cuttings taken from adult plants growing in the open air have failed with me on every occasion, with both Davidia involucrata and D. Vilmoriniana, and I have never been successful in obtaining the type of wood I desired. The shoots available are altogether too thick, and it appears impossible in the ordinary way to get a young, thin side-shoot in July or August that has grown in one season directly from an older branch. Whether or not shoots of the required type would be developed after cutting back an older branch remains to be tried.

Previous to the appearance of Mr. Grove's article, I concluded that the only reliable way to raise Davidias from cuttings was to secure wood from young trees; this conclusion would appear to be borne out by the opening paragraph of his article, where he states that the first plants sent to England by M. Maurice de Vilmorin were raised from cuttings; these, therefore, could only have been obtained from the seedling plant at Les Barres, which was at that time only a few years old. *F. P. Knight, Kew.*

OLEARIAS.

THE Olearias, or Tree Daisies, consist of some thirty or more species of evergreen shrubs, natives of Australia, New Zealand and the adjacent islands, a few of which are hardy in all but the coldest districts, while most may be grown in sheltered positions in mild localities, particularly near the sea. They make neat, attractive bushes, and there is no group of evergreen shrubs that flowers more profusely, and its members are deserving of wide cultivation in our gardens. Moreover, their season of flowering extends from May until August and carries on a floral display after many shrubs have passed out of flower.

Probably the hardiest of the genus is the popular New Zealand species, O. Haastii, which may be grown with ease throughout the country, and produces a mass of small, white blossoms in July and August. A compact, slow-growing shrub, it rarely attains more than four or five feet in height in this country, but it succeeds under almost all conditions and is quite a good town plant. O. macrodonta is a tall and ornamental species with very attractive, broad, Holly-like leaves, and makes a beautiful object when laden with its broad corymbs of small, white flowers in June and July. A. arborescens (syn. O. nitida) is a handsome plant, its broadly ovate leaves being bright green, shiny above and silvery underneath, and the rounded corymbs of white flowers are borne freely in May and June.

O. ilicifolia, the mountain Holly of New Zealand, is a tall-growing species with linear-oblong or lanceolate leaves, which, in spite of the specific name, are less Holly-like than those of O. macrodonta, to which it is similar in habit. O. Gunniana (syn. O. stellulata), the May-flowering Tasmanian Daisy Bush, is a highly popular and very floriferous species, its pure white blossoms remaining in beauty for a long period. O. nummularifolia is an uncommon looking plant with stout, dense branches and peculiarly formed yellowish leaves, but the flowers are not borne in the lavish profusion common to the genus.

O. semidentata is an attractive, medium-sized shrub of silvery appearance, bearing large, solitary, rose-tinted flowers, but it needs the protection of a wall. O. insignis (syn. Pachystegia insignis) is a remarkably beautiful shrub for mild localities, although it is probably hardier than is usually supposed, at any rate, it thrives on the light, Surrey soils. The large, obovate leaves of this species, six or seven inches long, are clothed with a silvery-white tomentum, and the large white flowers, three inches across, are borne on stiff, erect peduncles.

THE MANAGEMENT OF IVY.

EARLY spring is the best time to plant, prune or dress Ivy, and the cutting of it on walls or buildings should not be done later than March. All vigorous-growing Ivies will send out branches away from the wall, especially as they grow older, and if the cutting back is done too late in the spring, the chances are that new growth has begun, the old wood fails to break evenly again, and bare spaces are left to be an eyesore all the summer. When Ivy is well attended to it will present a green and even surface all the summer, but when there are bare spaces exposing the old stems it shows that the management is not correct. It often happens that old established Ivies impoverish the soil in which they are growing, and the colour of the leaves becomes more yellow than green. Where it is apparent that the plants are insufficiently supplied with nutriment, steps should be taken to remove as much of the old soil as is practicable and replace it with a rich compost. Where such a course of renovation is not practicable, two or three dressings of an approved concentrated fertiliser, sprinkled on the surface and watered in, will assist the plants to regain their proper colour. The first dressing may be given early in April, following at intervals of three or four weeks until midsummer. *W. A.*

ERICA CARNEA VAR. WINTER BEAUTY.

Of all the Ericas, there are none quite so fascinating as the subject of these notes, as it commences to flower in November and continues until the end of March. The accompanying illustration (Fig. 114) shows a patch in the Heath garden, taken in December, when in full flower; it always attracts attention, and since it is an easy subject to establish in most soils, except, perhaps, those containing much lime, it may be recommended as one of the best of the family to plant now, at the end of its flowering period.

A Heath garden is, perhaps, one of the most fascinating parts of the pleasure grounds, and if planting is carried out in conjunction with various shrubs which flower at different periods, and also shrubs which are noted for their colouring in the autumn, a really cheap and beautiful form of garden is secured, and very little time need be spent in attending it, except to keep down weeds in the early stages of growth, and cutting back after flowering to avoid straggling growth.

It may be interesting to readers to know that the subject of these notes is planted on a mound of clay, and I have yet to see Ericas in a more flourishing condition. The site is in a wild part of the pleasure gardens, and very flat, so we decided to make a certain area undulating. The top spit was taken off and wheeled to the edges of the area, and during draining operations the whole site was transformed into miniature hillocks, rising and falling in a natural way, made by the clay carted from the drainage works. In due course the top spit was wheeled back, and some common peat, leaf-mould and sand used when planting was done in March. By a proper selection of varieties, the Heath garden may be of interest the whole year through.

I have been struck with the resistance of Erica carnea var. Winter Beauty against the exceptional frosts and bad weather experienced while in bloom; further, during bright sunshine large numbers of bees which have visited the plants indicate the value of this variety, when there is practically nothing else for them, and anything which will assist the bees at this time of the year is of very great value. *A. Falconer, Cheadle.*

BULB GARDEN.

CROCUS CHRYSANTHUS.

One of our most appealing little Crocus species is C. chrysanthus, a native of south-eastern Europe, which blooms, as a rule, from January to March, and was late this year, although fully in flower by March 5. Like the other Crocus species with smallish flowers, it is of more value in the garden than if it were larger, and I am at present enjoying the beauty of several lots kindly sent me by Mr. E. A. Bowles, whom we all recognise as the authority on Crocuses. Mr. Bowles has been most successful in raising new seedlings of C. chrysanthus, and his skill in detecting the best of these has led to their being given varietal names. The typical form has rich yellow flowers with yellow or scarlet stigmata, but there are forms of varied colouring, such as C. c. var. caeruleus, white, tinted charmingly with blue; and var. albidus, white with a blue base. Two of the older ones, both very pretty, are C. chrysanthus var. fusco-tinctus, with yellow flowers, suffused with brown on the exterior; and C. c. var. fusco-lineatus, also yellow, but striped with brown on the outside. Of the new varieties, most of which have been raised by Mr. Bowles, one named E. A. Bowles, a fine butter-yellow, is lovely; var. Large Warley, is white, dark purple outside; C. c. var. Moonlight is sulphur with a purple base; C. c. var. Zwanenburg Bronze, deep yellow, bronze exterior, was raised in Holland, I believe; C. c. var. Canary Bird, scented and canary-yellow; C. c. var. Snow Bunting, a fine white; C. c. var. Bumble-bee, yellow, brown outside; and such varieties as Quaintness and Tom Tit. These and some unnamed seedlings were a great delight in early March, this year.

CROCUS SIEBERI.

Although there has been in progress for a number of years a growing appreciation of the beauties of the Crocus species and their varieties apart from the large-flowered Crocuses colloquially known as the "Dutch," and varieties of C. vernus, there is still an opening for a more widespread appreciation of their value in the garden. Worshippers of size are not likely to share in this appreciation, but to the many who can admire these delightful flowers, it may be stated they open up for them a new field of enjoyment. A considerable number are comparatively expensive and cost rather a large sum if planted by the dozen or hundred, but a proportion of lovely sorts are cheap enough without making an undue strain upon the resources of the would-be purchaser. One of these, Crocus Sieberi, is quite reasonable in price, and it flowers so early and is so attractive that it will be generally appreciated.

C. Sieberi hails from the Greek mountains and Archipelago, whence it was introduced in 1831. It has a roundish perianth, which is bright lilac, with a vivid yellow base and a beardless, orange throat, orange stamens and orange-scarlet stigmata. This species has also been called C. similis and C. nivalis. There is a very rare and beautiful variety which the writer would be delighted to possess again. This varies in colour from white to purple, with a rich golden-yellow base, and is feathered or veined with white and purple. The variety C. S. purpureus is deep purple, and is also rare in cultivation.

Compared with the Dutch varieties, C. Sieberi is small, but this is a gain rather than a defect, as it is better able to withstand the stormy weather generally experienced in February, when it comes into bloom. A large Crocus would be ruined in beauty in weather in which C. Sieberi would suffer little. This year it encountered exceptionally hard frost, then rain; then a dense mist at night, with frost in the morning and brilliant sunshine during the day. This indomitable little Crocus appeared to suffer little, and has been flowering freely, and is still (March 9) in full beauty.

Corms may be procured in early autumn and planted at once, about an inch deep in light, and half-an-inch in heavy soil. It is figured in Maw's *Monograph of the Genus Crocus*, t. 33, and in the *Botanical Magazine*, t. 1043 and t. 6036. *S. Arnott.*

FRITILLARIA LATIFOLIA.

This very variable species may, with decided advantage, be more frequently employed for naturalising in open woodland, in grassland and on the large rock garden; the sturdy stems are about one foot high, the pendulous flowers being comparatively large and of fine texture. The colouring of the blooms is fairly comprehensive and ranges from black to brown, purple, lilac and yellow, with many wonderful mottlings and chequered designs. I have had flowers with a rose-pink suffusion, and greys and yellows indivisibly confused—intriguing and very pretty, and really delightful.

Some years ago many named forms of F. latifolia were offered, and I retain recollections of Black Knight, Caroline Chisholm, Rembrandt, Van Spyk and Masia Goldsmith; these have, in all probability, long since disappeared, but an appreciable number of bulbs will produce a wonderful variety of flowers.

F. latifolia is very attractive when grown in pans or pots, and will thrive in almost any ordinary good, well-drained soil. It was introduced from the Caucasus so long ago as 1603, and its quaint beauty is worthy of a greatly extended recognition. *Ralph E. Arnold.*

FLORISTS' FLOWERS.

INTERMEDIATE SWEET PEAS.

The comments upon William Bateson (p. 62, January 26), were read with interest, but there appears to be some error in regard to intermediate forms of Sweet Peas. There is—or was—an intermediate type known as "bush," although I am not sure that any examples survive for the type was shy flowering, and of little value. During my residence here, I have never seen, or heard, reference to this type. I have not consulted my records, but the "bush" Sweet Peas were introduced, I think, some three or four years after the Cupids, by Messrs. W. Atlee Burpee and Co. Like the Cupid strain, the bush type appeared in California, and both came out of the tall type, before the advent of the Spencer, or waved, type. It is not unlikely that the bush type appeared unseen before the Cupids, although the latter were introduced first. On the other hand, the bush strain may have been the result of the influence of the Cupids, but it was never so stated. Without a doubt, these dwarf and semi-dwarf types appeared as a result of the persistent crossing, as did the hooded types, the Spencer and the Unwin types, and the newest multi-flowered type among the early-flowering kinds.

I may add that this multi-flowered type has this season made an appearance in a New Jersey grower's greenhouse, two or three years later than it showed itself in Canada. The advent of this multi-flowered type will assuredly mean beginning all over again, as was the case when Countess Spencer appeared, for no one will want to grow Sweet Peas producing only one flower stem from each leaf axil, when varieties producing two and three stems become available. *T. A. Weston, U.S.A.*

MOISTURE CONSERVATION BY MULCHING.

Having a very light, gritty soil, the drainage being further accelerated by a sharp slope, various means—of which the watering-can is not one—have to be employed to retain moisture during summer. Among these the mulch takes the foremost place. Going to work on the basis that there is almost always, even in the driest of soils, a constant upward flow of moisture from below, the business of the mulch is obviously to capture and retain that moisture before it is dissipated by coming in contact with the air. The principle is not a new one. Indeed, one of the oldest factors employed in agriculture for the conservation of this moisture is the dust mulch. With hoe, harrow or other tool, the land is repeatedly worked while in a friable condition until its surface is converted into a layer of soil so dry and finely-broken that it effectually prevents the evaporation of any moisture rising from below. In hot, almost rainless, countries, many crops have been, and are still being, successfully grown on this "dry-farming" principle, and every practical gardener is so fully cognisant of its value in maintaining growth during long dry periods that nothing more need be written on that point.

There are, however, many occasions upon which hoeing as a means of moisture conservation cannot be practised. Further, there are some soils which, dry as they may be, do not respond to such treatment. In such instances one adopts other measures, and one of these consists of mulching with some retentive material. In much of my own garden this system of top-dressing against the menace of drought is practically always going on, but early spring is its "high season." Shrubs like Rhododendrons and others often classed as peat plants, would stand a poor chance of succeeding in my light, sharply-drained slope were it not for this annual, or biennial, application.

The mulch may consist of half-decayed leaves, leaf-mould, decayed vegetable refuse, Seaweed for such as like it, old farmyard manure, spent Hops or peat moss, and the best of all these, as a moisture retainer, is the last. Like Sphagnum-moss, of which it is usually very largely composed, this form of peat does not only absorb water like a sponge, but holds it. I have tried all manner of things with that object in view, but nothing else has ever approached granulated peat-moss as an absorbent and moisture retainer. Moreover, this material is most extraordinarily resistant to decay, even when dug into the soil, and as a mulch it will long outlast anything else of the sort. It also possesses the great advantage of being free from weed seeds; insect pests dislike it; it is light and pleasant to handle, and birds do not scatter it as it contains no food.

Peat moss, before being used, is heaped-up outside for a few months and turned over once or twice. This breaks it up if lumpy, and it is in a better condition for use as a mulch after being converted into the semblance of a cool, damp mould. This weathering is stated to modify its rather high acid content, which may be advantageous in treating some subjects. Peat moss I mostly use alone, but it is sometimes mixed with leaf-mould or vegetable compost both for underground and as a top-dressing, especially for such Ericaceous and other subjects as need coolness at the roots.

By employing a mulch for the absorption and conservation of moisture one is, of course, only following what has been a process of nature since the world's vegetation began. From the same source many other practical hints of the kind may be gleaned, and one of these is what may be termed a living mulch. Just as turf and other herbage checks evaporation in the wild, so the gardener can grow mat-forming plants to serve the same end. Some of my slopes, for example, were so dry that they would not support Azaleas and, the pitch of the ground being steep, top-dressing had to be abandoned, for all the material was very soon at the bottom. But by covering the ground with some of the flat-growing Ericas, these speedily formed a most efficient check to evaporation. The soil beneath them was always cool, they gathered their own and other leaf-fall, and became the means of conserving moisture and humus.

Such a principle is, of course, applicable not only to the larger but also to the smaller subjects. Mr. Clarence Elliott's alpine lawn, for instance, demonstrates how lowly carpeting plants of dense growth will cover a thin, sun-beaten soil in which most others of a tufty nature and set apart from one another would languish from drought. This they are enabled to do by reason of the fact that they are themselves their own living mulch. Their blanket of verdure checks that surface evaporation alluded to, and so conserves sufficient moisture for their existence. Thus the same principle is pursued, the same end attained, in whatsoever form moisture conservation may be practised; and the discerning gardener will readily discover a dozen methods of putting it into application. *J.*

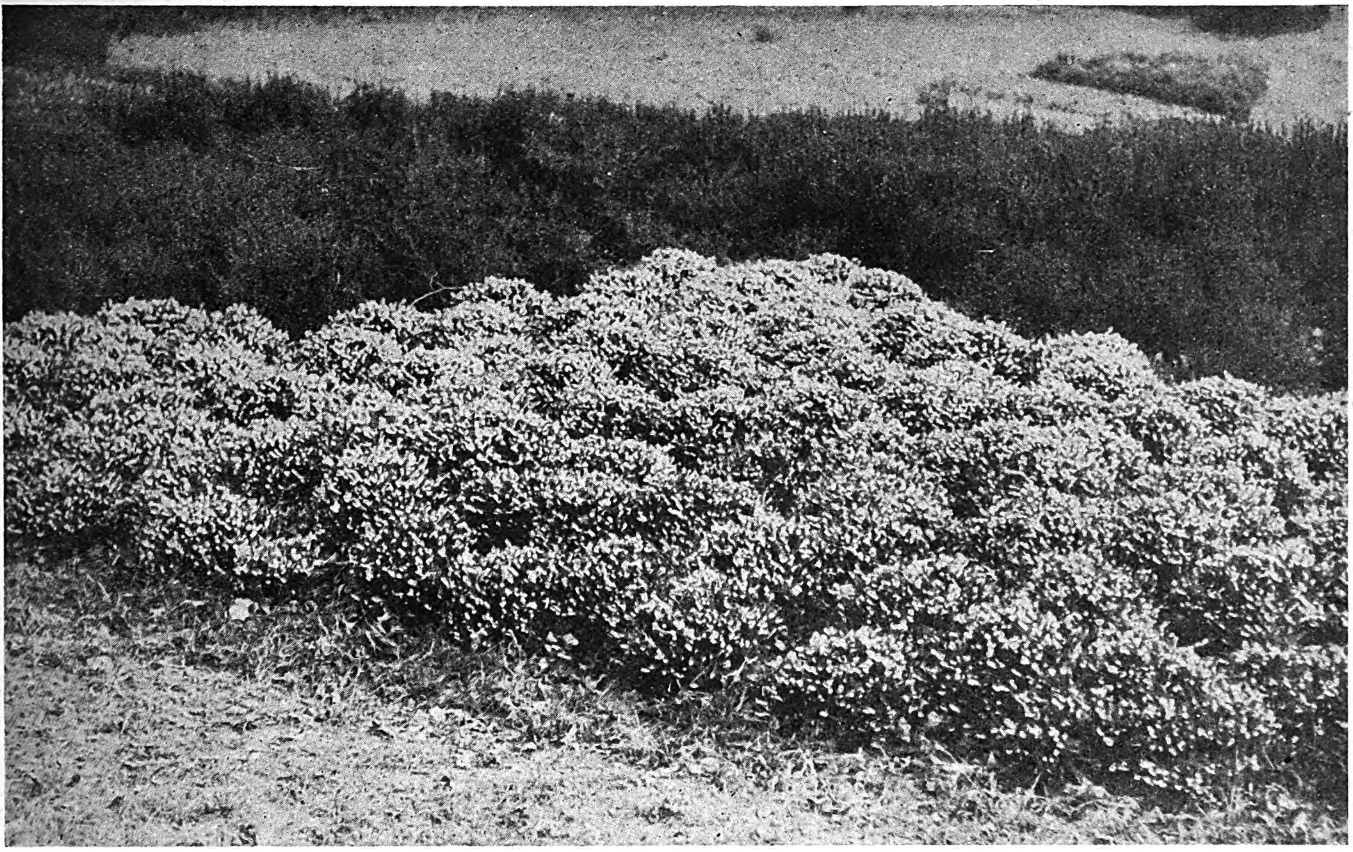

FIG. 114.—ERICA CARNEA VAR. WINTER BEAUTY AT THE ROYAL MENTAL HOSPITAL, CHEADLE.
(see p. 228).

TREATMENT OF SUGAR BEET SEEDS TO PREVENT SEEDLING DISEASES.

SUGAR Beet seeds, as will be seen, are seldom free from disease, and it is for this reason that some of the Continental countries have adopted various processes of seed disinfection. As seed dressings for Sugar Beet had not been tested for English conditions, the subject has been under investigation during the past three years, and the results are here outlined.

ORGANISMS RESPONSIBLE FOR SEEDLING DISEASES AND THE DAMAGE THEY CAUSE.

The parasitism of underground portions of seedlings by the fungus Phoma Betae, is stated to be mainly responsible for a poor "plant" establishment. This diseased condition of the roots of Sugar Beet seedlings is commonly and descriptively referred to as "blackleg," but this term also embraces injury caused by other fungi, such as Pythium de Baryanum and Aphanomyces laevis or by their combined effects. The damage caused by the Mangold pigmy beetle (Atomaria linearis) may be confused with the disease caused by blackleg organisms, as the attacks on the young seedlings by blackleg and by the beetle, usually occur at about the same time. The early symptoms of attack by the latter, however, may easily be distinguished from blackleg by the small excavations that the beetle bites out from the stem of the seedling just below ground level. Such seedlings, however, may eventually succumb to blackleg. The general symptoms of blackleg on the young seedlings are the appearances of disease lesions on the young stems at, or just below, soil level; these increase in size, become brown in colour, and finally cut off the water channels and in this way cause rapid wilting and death. If such plants are examined a black constriction at soil level is noticed, and the young root often becomes characteristically threadlike. If the plant is older and more vigorous when attacked it may recover; in this case the water supply is not completely cut off, and the diseased tissue is confined to the outer layers until it is finally thrown off. The damage done depends largely upon three factors, namely, the condition of the seed bed, the weather, and the infection of either the seeds (as shown by the presence of pycnidia of the fungus), or of the soil. To determine the extent of infection of commercial seeds, the varieties of Sugar Beet seeds were taken at random from twenty-six samples representing most of the English and Continental sources, and were examined at the Official Seed Testing Station, Cambridge. The infection of the seeds, *i.e.*, seeds which produced growth having disease lesions, varied between 44 per cent. and 89·5 per cent. The damage done by such infection of seeds when ideal conditions for fungus development obtain was demonstrated when seeds were sown in large boxes in unsterilised soil in a greenhouse. Approximately ten per cent. of the seedlings appeared above ground; of the remainder below ground approximately sixty per cent. showed signs of blackleg. In the field a large loss of plants frequently occurs when environmental conditions favour the disease.

TRIALS WITH VARIOUS SEED DRESSINGS.

About ten materials were tested, including two proprietary materials containing organic mercury, and one proprietary material containing organic arsenic in powder form for dry treatment of the seeds. One of the organic mercury materials gave outstanding results, and more exhaustive tests of this material were undertaken, and the results obtained were compared with the dressings of carbolic acid applied by both the sprinkling and steeping methods. The mercury material increased the plant in numerous trials in Northampton, Oxford and Cambridge by fifty per cent., and not only so, but the plant was stronger, as shown in one of the trials by an increased dry and fresh weight of 6·9 per cent. and 11·4 per cent., respectively. The results obtained with carbolic acid and with the dry treatment were not so uniformly beneficial, the former being distinctly harmful on a number of occasions.

The mercury material was the most effective substance used in reducing the number of diseased growths. In the examination of ten varieties of seeds it was found that there was a direct correlation between the intensity of infection of seed samples and a corresponding increase of plant in response to treatment with this dressing. No injury to the seeds or plants has been observed, but on the contrary, a definite benefit has usually been derived.

Trials to estimate the effect of the dressings on yield on the percentage of sucrose were undertaken in 1928. The results did not show a significant increase in yield or an increase in the percentage of sucrose, although the seeds receiving the mercury treatment produced, after singling, more roots per acre than the carbolic treatments, the organic mercury treatment, or the control. The explanation of this is that this seed dressing made the greatest reduction in the number of misses or gaps in the rows. Because of favourable climatic and seed-bed conditions for the seedlings, the disease, although present, was not severe in these trials (and there were few reports of its occurrence elsewhere) so that, for the season in question, its effect on yield was not shown under conditions which favoured the disease. As is well-known, a poor plant of Sugar Beet is of seasonal occurrence and is due, to an extent, to conditions which favour the pathogenic activities of the seed-borne organisms.

There seems to be little doubt that efficient disinfection of the seeds would be of great value in repressing seasonal outbreaks, and in this way act as an insurance against a plant failure in seasons unfavourable to the seedlings. Furthermore, it seems probable that the optimum plant would be established in the field, other conditions being favourable, if it were possible to judge more accurately the amount of seeds to be sown per acre; this assuredly would be made more simple by using either disease-free seeds or treated seeds, as then much would be accomplished towards assuring an even and satisfactory plant by eliminating the effects of that unknown factor, the presence of disease on the seeds. The optimum plant is of considerable importance, for it must be pointed out that too thick a plant, as well as too thin a plant, both exert an adverse effect on yield. The less obvious, although none the less serious effect of too thick a " stand " is to reduce the vigour of the plants before singling by over-crowding in the row.

In conclusion, it cannot be stated that such treatment of seeds would always result in an increased yield, but there is always the possibility that under conditions favourable to seedling diseases the yield would be increased as the result of the seed dressing and, conversely, would be considerably reduced if diseased seeds were not dressed.

The material in question is easily applied, is inexpensive, and requires no special equipment if the grower prefers to treat his own seeds. One gallon of water, in which five ounces of the material has been dissolved, is sufficient to wet 50 lbs. of seeds. An old, disused churn may be used in which to thoroughly mix and wet the seeds which have been sprinkled with the solution, or a watering-can with a fine rose will be found useful in applying the solution to the seeds spread on the floor. The seeds should be thoroughly and rapidly mixed to secure even wetting. The damp seeds are then spread out to dry, which process is a short one owing to the absence of any superfluous fluid. Alternatively, the rate of application is 125 grams of material, four litres of water, to be applied to twenty kilos of seeds. This season, English growers may obtain dressed seeds from some of the factories on the payment of a small premium. Owing to the very poisonous nature of mercury, care should be taken to avoid contaminating utensils used in feeding stock. *R. C. Woodward, B.Sc. Ph.D. (Cantab.), and W. A. R. Dillon Weston, M.A. (Cantab.).*

THE OENUS PRIMULA.

(Continued from p. 207).

LUTEOLA (Rupr.). Yellow Bird's-eye P. (Farinosae.)

A very attractive perennial species with a rosette of smooth, non-mealy, membranous leaves from four to eight inches long and three-quarters- to one-and-a-half inch wide, with lanceolate-elliptic, blunt blades, tapering to a distinct stalk; margins toothed; both surfaces more or less smooth, non-mealy. Flower stem fairly stout, four to seven inches tall, mealy upwards, bearing a dense, many-flowered umbel of pale sulphur-yellow blossoms. Corolla about five-eighths-of-an-inch across; lobes broadly heart-shaped; tube cylindrical, twice as long as the calyx. Flowers in August. Introduced in 1867.

Grows in moist mountain pastures in the eastern Caucasus and the mountains of Turkestan and Daghastan, reaching an elevation of 4,200 to 9,000 feet above sea-level.

Culture: As for P. japonica.

MACLARENI (Balf. f.). Maclaren's P. (Cortusoides-Geranioides.)

A handsome, deciduous, perennial species with a stout, branched, elongated, underground root-stock and oval resting buds covered with a few reddish-brown, hooded scales. The tufts of erect, bright green leaves have kidney-shaped or nearly circular blades about three inches across, blunt at the tip, heart-shaped at the base, borne on a rounded, hairy stem up to four inches in length; margins cut into seven to nine shallow, triangular, pointed, more or less toothed lobes, the teeth ending in a distinct, sharp point; both surfaces covered with glandular hairs. Flower stem up to twenty-five inches tall, covered with glandular hairs and bearing two or three super-posed umbels of rich crimson blossoms, with a yellowish, or yellowish-green eye, bordered with a deep magenta ring; they are borne on short, down-curved stalks. Corolla flat, about three-quarters of-an-inch across, with broadly heart-shaped or wedge-shaped, deeply bifid segments, with a tooth in the cleft; tube cylindric below, dilated upwards, with a ten-lobed ring in the mouth. Flowers in June. Introduced in 1915.

Grows among strong-growing grasses in valleys, in the Province of Whanghaido, in central Korea, at about 4,000 feet above sea-level.

Culture: Good, rich loam, in a cool, damp spot, with protection from damp and severe frost in winter, should suit it.

MACROCARPA (Maxim.). Large-fruited P. (Farinosae.)

A dwarf, small-flowered, Japanese species with a tuft of sub-diamond-shaped or diamond-shaped-spathulate, thin leaves, tapering gradually to a broad, winged stalk, in all from three-quarters of-an-inch to two inches long; margins towards the tip furnished with sharp, saw-like teeth; both surfaces smooth, non-mealy. Flower stem one inch to three inches tall, smooth, bearing a loose umbel of one to five white blossoms with a yellow throat. Corolla about three-eighths-of-an-inch across, divided into five broadly heart-shaped, deeply cleft lobes; tube not exceeding the calyx in length, cylindrical below, dilated upwards. (Illustrated in *Notes from the Botanic Gardens, Edinburgh*, 1913).

Grows in damp places on the mountains of Nippon, Japan, reaching an elevation of 4,500 feet above sea-level.

Culture: Plant it in fibrous loam and sand, in a damp half-shady spot.

MACROPHYLLA (Don). Large-leaved P. (Nivales.)

A handsome, robust, perennial species with a large tuft of broadly lance-shaped leaves, blunt at the tip, gradually tapering to a winged stalk dilated at the base, in all from three to ten inches long; margins furnished with distant, rounded teeth; upper surface more or less smooth, underside coated with white or yellow meal. Flower stem stout, mealy upwards, bearing one or two superposed umbels of pale or deep purple blossoms. Corolla nearly one inch across, with heart-shaped, rounded lobes; tube funnel-shaped, twice as long as the calyx.

Grows in damp mountain meadows in rich soil, in the Kumaon Himalayas.

Var. leariloba (Hook. f.). In this form the lobes of the corolla are narrow, deeply divided into two narrow, spreading lobes. Tibet, north of Sikkim.

Var. macrocarpa (Hook. f.). The leaves of this variety are broadly lance-shaped, blunt or pointed, two to five inches long, mealy beneath. Sikkim Himalayas, about 5,000 feet.

Culture: Good, rich friable loam and grit, in a damp, open position, is indicated.

MACROPODA (Craib). Large-podded P. (Petiolaris-Davidii.)

A little-known species from Szechuan, in western China, with a thick, woody rootstock which produces a tuft of elliptic or oblong-elliptic, rigid, papery leaves about six inches long, rounded at the tip, shortly wedge-shaped at the base, with the margins decurrent down the slender stem which equals the blade in length; both surfaces non-mealy, more or less smooth except on the midrib, where there are long hairs; margins furnished with blunt teeth or rarely small lobes fringed with minute hairs. Flower stems up to about seven inches tall, bearing an umbel of about seven blossoms, of which the colour and shape has not been recorded as the plant has only been gathered in fruit.

Culture: This species, which is not in cultivation, would probably succeed under the same cultural treatment afforded to other members of the section to which it belongs. *A. W. Darnell.*

(To be continued).

NOTICE OF BOOK.

Mesembryanthemum.

Since Vol. II of the *Flora Capensis* was published in 1861-2, there has been nothing in the literature of South African Mesembryanthemum at all comparable in wealth of observation and descriptive detail to the *Notes*[*] in which Mrs. Bolus has collated many of the papers she has communicated on the subject to the South African horticultural journals. For many years Mr. N. E. Brown has been engaged on a critical investigation of Mesembryanthemum, and has segregated it into many genera, thus confirming the suspicions of Haworth—the Nestor of Sarcophytology—regarding the composite nature of the genus. Mr. Brown's conclusions, which have been published in *The Gardeners' Chronicle*, together with those reached by other workers in the field, like Professor Schwantes, Dr. Karl

---

[*] *Notes on Mesembryanthemum and Some Allied Genera*, by H. M. Louisa Bolus, Hon. Curator Bolus Herbarium. Part 1, pp. 1-135, with twenty-one illustrations in colour and numerous figures in black and white. Speciality Press of South Africa, Ltd., 1928 (price not stated).

Dinter, and especially Mrs. Bolus, have led to the recognition of many novel genera, including **Nelia**, **Dorotheanthus**, **Carpobrotus**, **Lithops**, **Pleiospilos** and **Dinteranthus**, with embarrassing results to those systematists, who, trained like the writer in the *Flora Capensis* tradition of the genus, find their views obsolete.

Singularly fortunately placed for study of Mesembryanthemum, Mrs. Bolus has brought her well-tried faculties for critical observation into play in regard to scent and colour of the flowers, and their duration; the flowering period generally, pollenating agents, and many other points which escape the notice of all but acute observers in the field; if, therefore, her conclusions with regard to nomenclature are not always acceptable, the value of her observational work is not diminished. The book gains by the inclusion of numerous photographs of living plants and carefully drawn dissections of nearly all the species referred to, and if the coloured plates lack some measure of the brilliance of the veld flowers, the cause must be sought in the process of reproduction employed.

Botanically, the formal description of one hundred new species, which have a chapter to themselves, is of importance, as is the key to the genera of Cape Mesembryeae. There is an adequate index, and few misprints have escaped correction; but the systematic omission of reference to literature and authorities, as well as the irregular insertion of authors' names for new combinations, does not make for clarity in the pursuit of the synonymy.

The *Notes* will fill a long-felt want in schools, universities and herbaria in South Africa, and should help to foster interest in these diverse Succulents which, incidentally, have a place in the agricultural activities of the Union. *C. A. Smith.*

HOME CORRESPONDENCE.

Some Exhibition Experiences: and the late Mr. John Cypher.—Horticultural exhibitions are inaugurated as a means of supplying the public with something spectacular as well as educational, and certain societies recognise the fact that unless they obtain good exhibits their shows would not exist, consequently they go to some trouble to secure fine displays. Such committees do all they can to make exhibitors and their assistants comfortable, by making arrangements for transport to and from the station, providing breakfasts, sometimes a lunch, or dinner, where all may meet together and enjoy the hearty welcome which is so much appreciated. These notes are written with a view to emphasize the value of exhibits and exhibitors, and to encourage employers to allow their gardeners to exhibit, as it is a means of making a man strive to produce everything as near perfection as possible; it is also a means of gaining further experience. The man who is always kept within the walls of his garden will soon fall behind his fellow men. There is no other craft where the true spirit of comradeship is so fine as among horticultural exhibitors. As an instance, a certain exhibitor was held up on the railway and arrived at the show ground only a short time before judging should commence. Was he left in the cold? Certainly not. His friends and fellow competitors in the same class helped him to unload and stage his exhibit; and he won! Only those who exhibit know the time, study and forethought entailed to bring exhibits to shows, and sometimes the real hardships endured in bringing the produce to the standard that finds favour with the judges and the public. There are long hours of work, long journeys, and often little sleep. Those exhibitors who have large plant vans often use the van as an hotel, as it is often difficult, and sometimes inconvenient, to obtain accommodation for sleep and meals; they make their own comfort, and a friend is welcomed with refreshment ofte when this is very acceptable. One exhibitor caused some comment by installing electric light in his van and giving his address as the Hotel de Van. A visitor to the show made repeated enquiries in the town for that address! The late Mr. John Cypher, whom everyone loved so well, was really the first to use his van as his hotel; now nearly all the leading exhibitors adopt this plan, which brings me to the most important part of my notes. At the great Shrewsbury Show in 1928, during the reception of exhibitors and judges, due respect was paid to the late Mr. John Cypher, and many memories recalled, but, unfortunately, the exhibitors did not get a chance to put forward a scheme to perpetuate the memory of this great exhibitor, with the result that notes have appeared since in *The Gardeners' Chronicle* respecting it, and while the writer at first favoured the scheme put forward (see *Gard. Chron.*, November 24, 1928, p. 403) and was one of the writers, he has been very impressed with the views of Mr. Barnes (*Gard. Chron.*, January 5, 1929, p. 17), but there does not seem much enthusiasm on the matter to date, which is to be regretted. There is no doubt that the originator of such artistic displays of plants and flowers should have his memory honoured in a suitable way, and if there is one kind of exhibit which deserves special recognition it is that of the large group class, and it is only those men who stage them, and men like Mr. Barnes, who know the work entailed the value of such exhibits, as instanced by the Group Avenues at Southport and Shrewsbury, and their educational value to the general public. I could relate many interesting and humorous experiences, but these notes are written for the purpose of inviting all lovers of horticulture to subscribe to some fund such as has been suggested, to provide a lasting memory to one of the best exhibitors I have ever known, and one who always set a good example. *A. F.*

Lapagerias.—In reply to *W. P. W.* in your issue of February 23, I well remember the Lapagerias at the Royal Exotic Nurseries, Chelsea, as I was employed there at the time of the International Exhibition held at Kensington. I then went to Sion House, Brentford, and was there when the first Cocoanut Tree fruited and came to perfection in this country. The head gardener was presented with a Gold Medal in commemoration of the event. *E. Wills, Southampton.*

Freesias—Mr. Dalrymple (p. 166) desires to meet someone who knows Freesias in their native land. I cannot help him in that respect, but I spent ten years gardening in Australia, where I planted some Freesias on the edges of a flower border in my own garden. In four years they had increased so rapidly that they were growing like weeds all over the garden; not only did the corms multiply, but the plants seeded profusely. The Freesias thrived and flowered on hard, dry, gravel walks. As the soil was sandy and exceptionally hot and dry during the summer one would not expect anything to grow, yet, after the rainy season, they would commence to grow and flower, their strong scent being almost overpowering. They did not grow more than nine inches in height. Regarding culture here, your correspondent is correct. Freesias require water only when the soil is getting dry. They are not lovers of moisture. A light, sandy soil without manure or leaf soil would suit them best, gradually drying them off after flowering, and then placing them on a shelf near the glass, withholding water and giving them a baking in the sun until about August, when they should be repotted again. *H. Aldis, Lowestoft.*

Mistletoe.—In his introductory notes to *li abecés par ekivoche*, of Huon le roi de Cambrai (*Classiques français du moyen age*, Paris, 1925), in regard to the letter Y, M. Langfors quotes the existence of a manuscript, in which, opposite this letter, a scribe has made the marginal note "*gui*," of the pronunciation of which some doubt exists; further, that ancient tradition, which has been ascribed to Pythagoras, accords the letter Y as a representation of the two ways of human life—the parting of the good and the bad. Also that the letter has the significance of, and bears the name of, the Son, as in the cypher ΠΥΑ (Father, Πάτηρ; Son, Υἱός; Holy Ghost, Ἅγιον Πνεῦμα), *e.g.*, in some old Venetian scripts. Now "*gui*," which derives back from the Latin *viscum*, is the French word for Mistletoe. This association, for it hardly amounts to more than that, of a Y-like form, which is so marked a feature of the Mistletoe, with a religious significance, is, perhaps, not without interest. While many pre-Christian emblems or rites have passed on with a gap in their sequence, here, perhaps, we have a case where new links have been forged to make a complete chain. *H. E. Durham.*

Gardeners' Pay and Status.—I have been a gardener since 1886, and gained experience in well-kept gardens and nurseries, but I see little prospect for young men when 45s. per week with cottage is offered a practical, and experienced gardener, who is expected to grow first-rate Grapes, Peaches, Melons, Strawberries, Cucumbers, Tomatos and all kinds of flowering plants; keep a large house supplied with vegetables and salads all the year round, and maintain a large pleasure ground. I find myself handicapped with unskilled under-gardeners, as the long hours, stoking, etc., do not appeal to young men. I find gardening a very interesting occupation, but it is "all work and small pay." *H. P., Staffordshire.*

——I was very interested in the remarks of *B. C.* published in *The Gardeners' Chronicle* of March 9, p. 190, and judging from my own experiences, I think that it will be a hard matter for anyone to get much nearer the mark. What is the use of learning a trade if one is to receive the same treatment as an unskilled man? Who would expect a builder to pay casual labourers the same wage that his best bricklayers were earning? Yet this is exactly what many gardeners have to endure. Is it to be wondered that many young men are losing a genuine love of the work, when they have a constant struggle to exist? The wages they receive do not enable them to live comfortably. The "take it or leave it" style seems to be a pretty common complaint, and yet men are expected to "jump about" and keep things going under these very unfair conditions. I am sure that a live Professional Gardeners' Association would be a means whereby skilled men would receive recognition. *Another Young Gardener.*

Frost Injury to Apple Trees.—I find that I have only one tree (Lane's Prince Albert) split right down the stem by frost, as described by Mr. T. Wallace (p. 209); but there are small cracks in a good many others. In the winter of 1916-17 we had much more of this damage, as recorded by my father (*Southern Grower*) in *The Gardeners' Chronicle* of April 14, 1917, as follows:—"For the first time, I find slits caused by frost in the bark of many Apple trunks from a foot to two feet in length, and about half-an-inch deep. The trees most affected are those which are not over eleven years from the planting, and full of vigorous growth. The proportion of trees with these splits is not large—not over one in twenty in any variety. Cox's Orange Pippin is one of the most commonly affected varieties, as might be expected, seeing that it rarely misses anything that is going about." The splits on that occasion were always on the south side of the tree. No harm resulted, except that woolly aphis massed in the splits and needed attention for a year or two. *Market Grower.*

Salix lanata var. Stuartii.—The correspondence on this Willow (pp. 60, 107, 159, 208) has been of more than passing interest. The few notes I have been able to cull on the subject may be helpful. So far, I have not been able to find any support for the name S. lanata var. Stewarti, nor does S. lanata var. Stuartii appear to have found favour. Salix Stuartiana is figured in *Eng. Bot.* (Vol. XXXVI, t. 2,586), to which the following is appended:—"The Rev. Dr. Stuart, to whose name we dedicate this Willow, first gave us a specimen of it in August, 1782, from his garden at Luss, as the male plant of Lightfoot's S. lapponum, which is the Linnean arenaria, see t. 1,809. He found it in Breadalbane, where Mr. W. Borrer has since gathered our wild specimen, near the upper end of the Finlarig Burn." An exhaustive description follows. Referring to more recent work, I find Dr. Moss in *The Cambridge British Flora* (may one express the hope that this wonderful work will be completed ?) supports the above and tells us it was named after the Rev. Dr. John Stuart, of Luss, Dumbartonshire, but gives it as a synonym of S. lapponum, L., a view which is supported in the *Kew Handlist of Trees and Shrubs*. Dr. Moss gives S. lanata × lapponum as a distinct plant from the above. Should the plant referred to on p. 208 of *The Gardeners' Chronicle* prove to be this hybrid from Aberdeenshire, and as the plant has found its way into the trade (p. 159), it is to be hoped Mr. Fraser will be successful in his efforts, and that the plant will receive an authentic name. *J. Blades.*

FOREIGN CORRESPONDENCE.

HIPPEASTRUMS OUT-OF-DOORS.

THE illustration (Fig. 10) and note (p. 27) relating to Hippeastrums out-of-doors in Kenya Colony prompts me to mention that the commercial culture of these bulbs is now carried out on a big scale in various parts of Florida and California. The growers, in most cases, started out with Kerr's and Veitch's finest named sorts, and have since, by crossing, extended the range of colours. Strong bulbs are easily raised in about three years, and to-day, nearly all seedsmen offer dry bulbs during the winter at reasonable rates. The wholesale dealers offer first-class strains at around $35 (£8 10s.) per hundred, while the usual retail price is about three shillings each. Vast numbers of bulbs are sold, the greenhouse men, in not a few instances, growing the flowers for cutting. Named sorts are not offered, as propagation by offsets is naturally slow. Being so easily crossed and growing so readily out-of-doors, it is not surprising that considerable variation exists, and, as might be expected, some growers make great claims for their Hippeastrum strains. Certainly, some of the blooms are immense, although rather coarse. Some, as a result of cross-breeding, show a tendency to crop more than once in a season.

The chief of the Agricultural Department greenhouses at Washington, D.C., has for a number of years done much breeding of Hippeastrums and each year a public exhibition of many hundreds of plants is given and, usually, one or two seedlings are named after notable persons. This Government collection is stated to be the finest in the world; I have not seen it, but, as it was originally started from the finest English varieties, I do not doubt that it is good, as Superintendent Byrnes has, naturally, only retained the finest of his seedlings. The collection is stated to contain some fine pure white sorts. *T. A. Weston, New Jersey, U.S.A.*

THE NATIONAL IMPORTANCE OF FRUIT-GROWING.—I .

(*Concluded from p.* 211).

IT is proposed in this final article generally to survey the position of English fruit-growing, to look at it from the point of view of the specialised fruit grower, and of the general farmer, and, if possible, to show the likelihood of a profitable return from the industry.

We have been considering in the last three articles the demand for, and supply of, fruits in this country, and the costs involved, which considerations have, in the main, been based on statements made by Mr. Seabrook in his paper to the Farmers' Club (see pp. 125 and 146). This paper, while giving great food for thought, tends to produce an unduly optimistic view towards Apple-growing. It is undoubtedly true that, in spite of the irregularity of supply of home-grown Apples, there are growers who can, and do, make Apple-growing pay. Equally, there are all too many growers who are failing to show a profit. In the writer's opinion, there are too many people who are inclined to look on Apple-growing as a side-line and an adjunct to ordinary farming, instead of realising that of all branches of fruit-growing it is, perhaps, the one which most bears out the remark of the Commissioner of Horticulture that "fruit-growing is much more allied to ordinary industry than are the ordinary farming practices."

If the intending Apple grower learns his job thoroughly as a fruit farmer, and is prepared to lock up his capital and get no return for at least seven years, and, in addition, has chosen the right variety for his locality, not always an easy matter, then he may make his venture a real success.

There is, nevertheless, a branch of the industry which shows brighter prospects. Soft fruits are in a thoroughly good competitive position on our home markets. They are in greater demand than ever, and the demand seems yet to be increasing, particularly for Black Currants. Less capital is required for planting and growing to productive age and this capital remains unprofitable for only two-and-a-half years, some only for eighteen months. The culture of soft fruits, although individual and needing care, may be successfully practised on arable farms. Weighing, packing and preparing for market are done in the open field, and no money is required for sinking in stores or graders.

The cost of establishing a plantation of Black Currants or Strawberries is in the neighbourhood of £40 per acre. This figure includes all costs up to the time of the first crop, eighteen months or so after planting. This fruit crop should bring in at least £30 (three-quarters-of-a-ton at £40). The next year's costs will amount to £40 or less, and the crop should be a full one. Between £40 and £50 have to be set against this crop, which should be worth £80 to £100. In subsequent years the figures remain approximately the same, and a Black Currant plantation should give at least six full crops and a Strawberry bed three. In each instance the figures for returns are understated, and therefore a larger profit is possible.

Fruit-growing then is, as a whole, a job for the specialist. Certain of its branches need less specialised training than others. A profitable return can be made, but it seems probable that the ordinary farmer would be well advised to consider soft fruits rather than Apple-growing. *A Norfolk Grower.*

VEGETABLE GARDEN.

BRUSSELS SPROUTS.

I HAVE been much interested in the correspondence *re* Brussels Sprouts. Mr. Bradley's results (see p. 87) from growing the crop in firm land should be remembered by all growers, and his practice of spreading a coating of manure over the entire surface is one followed by many successful Brassica growers; it is, I am told by no less an authority than Mr. Robert Scarlett, followed in Belgium and Holland with marked success, and he has confirmed it in Midlothian.

Mr. Bradley's last remark is the one I specially noted: "If there is a fault with those I have grown it is that they are too large." He grew Messrs. Dickson and Robinson's "Exhibition," an excellent, well-known, standard variety. My thoughts went back over a great many years when Messrs. Dobbie and Co. were exhibitors of Brussels Sprouts at a vegetable show at Chiswick, on the occasion of a Vegetable Conference. Their Sprouts were too large in the opinion of Mons. Vilmorin, who considered they were "much too large, the size of boys' marbles is best."

Mr. James Page, in your issue of March 2, surely takes us to quite the other extreme. His Sprouts, according to your measurements, were three to four inches in diameter. I could not conceive that such large ones are popular until I read Mr. Page's letter (p. 116): "They command the best market; they certainly look better in shops; and there is less waste; they cook a good colour and are of excellent flavour"—these are his words. So long as they command the best market, I suppose they will be grown by the hundreds of acres he speaks of. But; personally, I prefer a Sprout one-and-a-quarter-inch to one-and-a-half-inch in diameter for my own use, and so do very many of my friends. In the last trial of Brussels Sprouts by the Royal Horticultural Society, at Wisley (1923), the lots sent in were divided into two sections:—(a) Dwarf varieties, up to two feet; and (b) Tall varieties (over twenty-four inches); and each section was sub-divided into five sub-sections:—1, Sprouts, small; 2, Sprouts, small to medium; 3, Sprouts of medium size; 4, Sprouts, medium to large; and 5, Sprouts, large. Unfortunately, no measurement of the size of "button" is given. There is this year another trial at Wisley, and I am sure Mr. Chittenden can be induced to record this feature. Perhaps Wisley has records, and it would be interesting if they could be given.

At a lunch at Wisley last month I sat next to Mr. E. A. Bowles, and we had Brussels Sprouts—nice small ones we both appreciated. He told me of Canon Ellacombe's recipe for cooking Sprouts, a recipe Mr. Bowles has followed for twenty-five years:—"Have small Sprouts ready prepared for cooking, have the pot half to two-thirds full of boiling water, drop in the Sprouts, and when the water boils again allow the Sprouts to remain in for only four minutes, remove and serve at once, and a dish fit to set before a king is the result." I have told my wife that I want my Sprouts cooked in this fashion in future; she doubts whether four minutes is long enough, but we shall see next season. *William Cuthbertson.*

ASPARAGUS.

THE culture of this desirable vegetable has reached a high standard in the Vale of Evesham, being mostly grown by a host of small growers, who find it best, owing to the heavy nature of the land, to grow the plants in single rows, generally one yard apart, on well-ridged and cultivated soil. They generally sow their own seeds, saved from selected plants, and always have a patch ready for planting out, one foot apart, to replace exhausted stools. Either one- or two-year-old plants are used, these being planted on ridges. The remarkable part of the cultivation, as practised by these growers, is the earthing up. In the late autumn, with the aid of a two- or three-tined fork, the soil in the alleys is dug and turned clean over on to the rows, generally in great lumps, just as it is dug out—this is, needless to say, heavy work. Frost is always welcomed as a pulveriser and many anxious faces are seen if it does not come. In early spring the ridges are forked over, the soil being made fine; heavy dressings of soot are applied and are highly beneficial to the "grass."

When cutting commences, every stem is cut, usually at about nine inches in length, with an Asparagus knife; the treatment detailed above results in the "sticks" being blanched for more than half their length.

Grading is always practised, and the small stalks are known as "sprue." The sticks are bunched with the aid of a useful bunching stand, and are tied up with Willow bands, the Willows growing by brooklets which run by the gardens.

An Asparagus show is held annually at Badsey, the numerous cups being won by grand produce.

The high standard of produce attained by these market growers would astound many private gardeners, and at the auction following the show high prices are always realised for the prize bundles.

During the earlier years of growth, the sides of the Asparagus ridges are cropped with French Beans and small salad crops. Cutting finishes after Ascot week, and at this period prices are generally high. *C. H. Emmett, Taplow.*

SOCIETIES.

GUILDFORD GARDENERS'.

The series of winter lectures was concluded on Tuesday, March 5, when Mr. W. Auton spoke on "The Chemistry of the Garden."

In introducing his subject, Mr. Auton said that chemistry was the science of matter, and matter is the basis of all industries, and of life itself. Chemistry might therefore be regarded as occupying a foremost place among the sciences. Horticulture quite as much as, perhaps more than, any other industry, rests on a chemical basis, for the life cycle of the plant from seed to seed is one long series of chemical reactions.

The lecture which followed covered a wide field and was highly technical. It dealt with the essential elements necessary to plant life, and a part of the general argument referred to the pressing problem of finding a substitute for farmyard manures, to replace the soil elements which grown crops had withdrawn from it. Mr. Auton said that a better use should be found for vegetable matter than the bonfire—by means of which much potential fertilising matter is destroyed. If a bonfire must be made to burn woody matter or diseased plants, dry bins should be provided to conserve the ash until it could be applied to growing crops.

After an interesting discussion which followed the lecture, Mr. Mackay, of The Hill, Witley, expressed his pleasure, as an Old Kewite, at meeting Mr. Auton, another Old Kewite, and proposed a hearty vote of thanks for the interesting address.

The President, Mr. W. T. Patrick, referred to the long illness which followed the accident to Mr. Auton last June, and congratulated him upon his recovery and also upon his appointment as gardener at Moreton Hall in Warwickshire, and while it was regretted he would be leaving the Guildford district, he would carry with him all good wishes for his future happiness and success. Mention was made of a further loss caused by the removal of Mr. G. T. Watson, who has taken up the appointment of gardener to Viscount Boyne, Burwater Hall, Bridgnorth.

It speaks well for the good fellowship in the Association that both Mr. Auton and Mr. Watson will not sever their connection, but will remain in membership.

GLASGOW AND WEST OF SCOTLAND.

At the recent meeting of the Glasgow and West of Scotland Horticultural Society, Mr. Isaac Fleming, Superintendent of Parks, Paisley, who presided, referred to the loss the Society had sustained by the death of Mr. George Hunter, a member of the directorate.

The lecturer for the evening was Mr. Andrew Harley, Devonhall, Muckhart, Perthshire, who with the aid of an elaborate series of lantern slides described the flowering shrubs growing in his garden. In discussing their suitability for small gardens, he attributed their popularity to their usefulness and ease in cultivation. Once shrubs had been properly planted, the cost of upkeep was small, and contributed to the solution of the labour difficulty. There was such a large number to choose from that he did not understand why anyone should fill up their shrubbery border with such things as Laurels, ponticum Rhododendrons, Aucubas, Hollies, etc., mostly clipped into tight balls, thus losing their natural grace, when shrubs could be planted which will produce flowers from early spring until the end of October. Emphasising the importance of pruning, he explained that shrubs which flowered on the wood made in the previous season should be pruned immediately they had flowered, by cutting out the old wood, while those that flower in the autumn on wood made the same season should be pruned during winter or in early spring when growth is starting. All flowering shrubs, like herbaceous plants, respond to good treatment, and to get the best results it pays the grower to treat them in the same manner as Roses by giving the soil a mulch of manure in spring.

The following shrubs were described as easily grown, suitable for planting in small gardens, and producing blooms from early spring until autumn: — Jasminum nudiflorum, Daphne Mezereum, Forsythia suspensa, Cydonias, Berberis Darwinii, B. stenophylla, Viburnum Carlesii, V. plicatum, Lilacs, Rubus deliciosus (the Rocky Mountain Bramble), Philadelphus Lemoine hybrids, Deutzias, Cistus ladaniferus, C. laurifolius, Buddleias, Hypericum patulum Henryi and Hydrangea paniculata grandiflora.

CARDIFF GARDENERS'.

The fortnightly meeting of the above Association was held at the Queen's Hotel, Cardiff, on March 12, Mr. W. Bennett occupying the chair. There was a large gathering, which included many wives and friends of the members, who were all interested in the lecture and demonstration given by Mr. H. R. Farmer, of Cardiff Castle Gardens, on "Jam-making and Vegetable Bottling."

Mr. Farmer described in detail the various methods adopted in the making of jam and the bottling of fruits and vegetables, and he displayed the various utensils required, together with many bottles of jam and vegetables. He maintained that there are only three kinds of vegetables that are worth bottling, from a gardener's point of view, namely, Peas, Beans in variety, and Tomatos, and he considered water was preferable to brine for this purpose. Varieties of Peas which he had found most suitable and which keep their colour well, are Selected Duke of Albany, Peerless, Little Marvel, Duchess of York, King Edward and Ideal. All Peas for bottling, he stated, should be gathered when young.

An interesting discussion followed, and many questions were asked, all being answered concisely by Mr. Farmer.

The first prize for the best bowl of hardy spring flowers was awarded, to Mr. H. Jenkins, while for three plants of Polyanthuses, Mr. Cosham was first, and Mr. Franklin second. In the class for ten "seed" Potatos, sprouted, the first prize went to Mr. H. Jenkins; second, Mr. J. Jones, and third, Mr. D. Burns. Six points were awarded to Allan Gibbs, Esq. (gr. Mr. Hardwick), for Violets, Mr. Jenkins and Mr. Jones, for Perpetual-flowering Carnations, and Mr. Jones for a magnificent Hippeastrum, respectively.

For the most points secured during the half-session, Mr. H. Jenkins was first, and Mr. Baker and Mr. Jones shared second place. Mr. Price was awarded the prize offered by the Chairman for obtaining the most new members during the session.

PROFESSIONAL GARDENERS'.

The monthly meeting of the above Association was held at the Guildford Hotel, Leeds, on March 9.

Mr. Besant, the Parks Superintendent of Harrogate, gave a most interesting paper on "A Retrospective View of Horticulture." In tracing an outline of the training of gardeners before the war, the lecturer touched on the old system of a youth spending three years as an apprentice in a first-class garden, then working up by stages of one-and-a-half to two years at other places, doing both inside and outside work, until he was able to take a general foreman's place. About sixteen years elapsed before he was thought capable of taking a head gardener's place. He also stated that the best recruits for the parks were those from private gardens.

There was an animated discussion after the lecture as to the best training for gardeners for public and private service, opinion being about equally divided as to whether youths take as much interest in the profession as they did before the war. Mr. Besant maintained that the present day youth, if given a chance and a little encouragement, is quite as good as the pre-war youth. Replying to a question, "Do present head gardeners take as much interest in their young men as before the war?" Mr. Besant stated he thought they did; but the members were divided on the point. All agreed, however, that it is the duty of head gardeners to help the young men to the best of their ability. The lecturer was of the opinion that the P.G.A. and the Parks Superintendents' Association should work together to raise the status and pay of the horticultural worker generally.

The next meeting of the Association will be held at the Guildford Hotel, Leeds, on April 6, at 7 p.m., when a lecture on "Growing Exhibition Vegetables" will be given.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS'.

What may be termed the most successful gathering in the annals of the above Association took place at the White Horse Hotel, Birmingham, at the end of last month. One-hundred-and-forty-six members, together with their wives and friends, participated. The horticultural and allied trades were well represented, and in response to the appeal of the Chairman on behalf of the social and prize fund, £11 11s. 0d. was collected.

In submitting the loyal toast of the evening, the Chairman stated that he knew, if it were possible, the health of His Majesty the King would be drunk with more fervour than ever before by them, on this occasion, seeing that such a gracious and happy message had been received from Her Majesty the Queen in reply to their loyal and humble message of sympathy through the Chairman. A letter was read from the Lord Mayor of Birmingham, Alderman W. Byng Kenrick, J.P. expressing his desire to become a patron of the Association, as he appreciated the valuable work it was doing.

The "Success of the Association" was proposed by Mr. C. Ray, and the Chairman, in response, dealt with the aims and objects, together with the future policy of the Association. Fifty per cent. increase in membership was recorded during 1928, and it is anticipated that instead of fortnightly meetings being arranged for the autumn and spring of 1929-30, meetings will have to be arranged weekly, alternate Mondays being devoted to the professional gardeners, and the others to amateur members. Lectures would be arranged to meet the requirements of each.

The Chairman expressed the thanks of his Committee to the ever-ready assistance which they had received from the press, especially *The Gardeners' Chronicle* and the Birmingham City local press. Prizes were distributed to several members for essays submitted during the spring of 1928.

ANSWERS TO CORRESPONDENTS.

Names of Plants.—*G.* 1, Erica arborea; 2, E. carnea; 3, Vaccinum Myrtillus; 4, not recognised. *G. P.* 1 and 4, Colletia spinosa, Lam. (syn. C. armata, C. horrida, C. polyacantha, C. spinossima); 2, Colletia teniculata; 3, Olearia erubescens, from Australia; 5, appears to be Lonicera nitida, but only four undersized leaves were in the parcel, and a slender twig showing that the leaves were opposite before they fell off.

Pelargonium Unhealthy.—*W. W. F.* Parasitic fungi were not present on the Pelargonium plant, but saprophytic fungi and eelworms were in evidence. Fresh material may show that the damage is due to the stem eelworm, or may have been induced by low temperature and an excess of atmospheric moisture.

Tomato Plants Diseased. — *A. C.* The Tomato plants are attacked by a Phytophthora foot rot. The wilted plants should be removed and burnt, and the remainder watered with Cheshunt compound. Careful attention should be paid to watering, and the temperature kept so low as possible without impairing the health of the plants. Shade the plants during bright, sunny weather.

MARKETS.

COVENT GARDEN, Tuesday, March 19, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Plants in Pots, etc. : Average Wholesale Prices.

Remarks.—As regards white blooms, the conditions are lightly improved; more cut white Azalea, Narcissus Grand Primo and N. ornatus have been available in the English department, and more double white Stocks in the French department, but there is no prospect of any fall in prices owing to the increased demand for the great festival in Wales this coming week-end. Best quality Daffodil blooms from home-growers are still realising good prices, but cheaper grades are considerably on the increase from Cornwall and the Channel Islands, other arrivals including white Narcissi, Wallflowers, Forget-me-nots, Tulips, Violets, Irises and Anemones. Tulips have been generally shorter, especially Darwins, and prices have been on the up grade during the past week. Roses are now drawing more attention, being much finer in quality and a better selection on offer, but supplies are still below requirements. In the pot plant department business begins to show some improvement, after a very dull time. More flowering plants are now on sale, which include white Marguerites, white Spiraeas, Erica persoluta, Acacia Drummondii and Boronia megastigma, also a few blue and white Hydrangeas. There is also a good supply of Daffodils and Hyacinths, and Ferns are gradually improving in quality.

Remarks.—Trade conditions in the market have been somewhat variable this week, but at the moment the tone is moderately good. The Cape fruit shipments are heavy, consisting mainly of Grapes, Nectarines, Pears, Plums and Peaches, and the demand is quite good. The Apple market is fairly steady, but prices are on the easy side for both imported produce and the English Bramley's Seedlings that are now being marketed. Hothouse Grapes are selling at prices which are no doubt satisfactory considering the competition of other choice fruits from South Africa. Forced Rhubarb is maintaining good prices and continues to sell well. A few English Tomatos are now available, but prices are rather high. Tomatos from the Canary Islands are not plentiful, and they maintain comparatively firm values. Cucumbers sell with more freedom after a period of slack trade, and quantities show an improvement almost each day. Forced Beans are selling better, although prices are not higher. The latest shipment of Beans from Madeira is in good condition and the Beans have realised higher prices. Forced Potatos from Guernsey have shown some increase in price since last week. New Potatos from Algeria have met a good market as new Potatos are comparatively scarce. Salads, mainly from France, are selling well at prices which must be considered almost prohibitive. Some very good Broccoli is now arriving from Cornwall and is selling remarkably well, especially so in comparison with figures which are ruling for St. Malo and Roscoff produce. There are rather better supplies of green vegetables which have brought about lower prices in that market. Root crops remain in steady demand with prices a shade easier. The trade in old Potatos is moderately brisk, especially for top-grade varieties.

GLASGOW.

Prices moved irregularly in the cut flower market last week. Tulips advanced in price, William Copland, Bartigon, William Pitt, Le Notre, Princess Elizabeth and Couronne d'Or ranging from 1s. 3d. to 1s. 9d. for 6's; and Peach Blossom, Lucretia, Murillo, Tea Rose, Flamingo, La Reine and Luisante, 10d. to 1s. 6d. Daffodils, were also dearer; King Alfred was worth 2s. 6d. per dozen; Golden Spur, Emperor, Victoria and Sir Watkin, 1s. 2d. to 1s. 6d.; Princeps and Henry Irving, 8d. to 10d.; and ornatus, 10d. to 1s. 3d. On the other hand, price declines were registered in Carnations at 2s. to 4s. per dozen (all colours); red and pink Roses, 8s. to 12s.; Lilium longiflorum and Richardias, 6s. to 7s.; Anemones, 10d. to 1s. 3d. per bunch; Ranunculus, 1s. 6d. to 2s.; Myosotis, 9d. to 1s.; and Snowdrops, 2s. to 3s. per dozen bunches. Marigolds sold at 7d. to 9d. per bunch; Wallflowers, 4d.; Lily-of-the-Valley, 2s. 3d. to 2s. 6d.; Cypripediums, 1s. each; and Mimosa 8s. to 10s. per pad.

The feature of the fruit market was an appreciable advance of 2s. 6d. to 4s. per case in the price of Valencia Oranges; ordinary 420's were quoted at 30s. to 38s.; large, 420's, 38s. to 48s.; 200's, 21s. 6d. to 32s.; 240's, 22s. 6d. to 32s.; 300's 22s. to 28s.; 360's, 21s. to 24s.; and 500's, 21s. to 24s. Jaffa Oranges, 144's, made 22s. to 23s.; 152's, 22s. to 23s.; and 120's, 21s. to 22s. Californian seedless Oranges, 126's, sold at 27s.; 150's, 28s. to 29s.; and 176's, 30s. to 31s. Apples were firm in price, Winesap, ex. fancy, realising 12s. to 13s.; Rome Beauty, 11s. to 13s. per case; and Albermarle, 21s. to 31s. 6d. per barrel. Grape Fruits, Florida and Arizona, 70's, sold at 21s. to 22s.; 80's, 23s. to 24s.; while English hothouse Strawberries made 40s. per box, and the first consignments of new English Tomatos, 7s. per lb. Home-grown Grapes were 4s. to 4s. 6d. per lb.; Pineapples 3s. 6d. to 4s. 6d. each; South African Peaches, 4s. to 5s. 6d. per tray; Nectarines, 3s. to 4s. 6d.; Plums, 5s to 6s.; and Grapes, 10s. to 13s. 6d.

In the vegetable market Lettuces were in active demand at 12s. per crate, while Cauliflowers realised 8s. to 10s. for 24's; Cucumbers (Dutch), 10d. to 1s.; English, 1s. 9d.; and Rhubarb realised 6s. per cwt. Guernsey Beans declined from 8s. to 3s. per lb.

SCHEDULES RECEIVED.

Royal Agricultural Society of England.—Flower Show at Harrogate, on Tuesday, Wednesday, Thursday and Friday, July 9, 10, 11, and 12. Secretary, Mr. T. B. Turner, 16, Bedford Square, London, W.C.1.

Saffron Walden Horticultural Society.—Flower and Horse Show, in the North Deer Park, Saffron Walden, on Thursday, July 25. Secretary, Mr. George Collin, 3, Landscape View, Saffron Walden.

Leicester Abbey Park Flower Show.—Fortieth Annual Show, in Abbey Park, on Tuesday and Wednesday, August 6 and 7. Secretary, Mr. R. Lisle, Superintendent, Abbey Park, Leicester.

Brighton, Hove and Sussex Horticultural Society.—Spring Show in the Dome and Corn Exchange, Brighton, on April 10 and 11. Rose, Sweet Pea and Carnation Show, Wednesday and Thursday, July 3 and 4. Chrysanthemum Show, Tuesday, Wednesday and Thursday, November 12, 13 and 14. Secretary, Mr. H. J. Bingham, 128, Queen's Park Road, Brighton.

West of England Chrysanthemum Society.—Exhibition, in the Guildhall, Plymouth, on Tuesday, Wednesday and Thursday, November 5, 6 and 7. Secretary, Mr. S. Collecott, Florist, 52, Cobourg Street, Plymouth.

Yorkshire Flower Show and Gala.—At York, Tuesday, Wednesday and Thursday, June 18, 19 and 20. Secretary, Mr. P. Mennim, The Assembly Rooms, York.

CATALOGUES RECEIVED.

Acme Chemical Co., Ltd., Tonbridge, Kent.—Weedkillers, Fumigants, Fertilisers and Sundries.

Boulton and Paul, Norwich.—Revolving Shelters and Garden Rooms.

Slug-Mort Company, Penzance.—Slug-Mort (slug and snail exterminator).

Andrew Ireland and Hitchcock, Marks Tey, Essex.—Special offer of Sweet Pea Plants, Gladioli, Bedding Plants and Seed Potatos.

Clarence Elliott, Ltd., Stevenage, Herts.—Seeds of Annual and Perennial Flowers.

Little Munden Nursery, Ware, Herts.—Hardy Herbaceous Plants.

Treseder, Ltd., Cardiff.—Dahlias, Chrysanthemums, Sweet Peas, Carnations, Bedding Plants, etc.

A. and W. Perry, Enfield, Middlesex.—New and Rare Alpines and Perennials, Alpine and Perennial Seeds, Gladioli, Water Plants, etc.

Cooper, Taber and Co., Ltd., London, S.E.1.—Wholesale Catalogue of Agricultural Seeds.

The Future of the Potato

UNDER the somewhat cryptic title "Potato Futures" (see p. 251), Mr. William Cuthbertson—after reviewing briefly the recent past of the Potato—looks with an enquiring eye to the future. What, he asks, is to be the policy of those engaged in raising new varieties? Are they to go on working along present lines, or are they to venture along other and older lines? Until the early years of the present century, the Potato breeders' only care had been to produce races of Potato superior in yield and quality to the best of their predecessors. They were successful. Each decade saw the introduction of new varieties of outstanding and enduring merit. Then, however, came the Wart Disease menace. Mycologists predicted that unless precautions were taken this disease would render Potato-growing impossible. Whether they were right or wrong in this gloomy prognostication no one knows. It is probable that they were wrong. But it is certain that in view of the seriousness of the menace the Ministry of Agriculture was right in taking the most drastic precautions to prevent the spread of the disease. Nor does our indebtedness to the Ministry end there, for it was responsible for the discovery that varieties exist which are immune to Wart Disease, and for the establishment of the Ormskirk Station at which all varieties of the Potato could be, and have been, tested for susceptibility to, or immunity from, Wart Disease.

It will be seen, therefore, that Wart Disease has become a sort of King Charles' head in the Potato picture. The fear of the spread of the disease has influenced the development of the Potato. Mr. Cuthbertson asks, and in our opinion asks very cogently, whether the same fear shall be allowed to govern the future development of the Potato. That it has governed the development of the Potato in the immediate past is clear. Instead of fixing their attention exclusively on yield and quality, the plant breeders of the last decade or two have had, perforce, to pursue not a single but a dual objective. They have had to keep one eye on the yield and quality of their seedlings, and the other on the response of these seedlings to Wart Disease. It is, therefore, perhaps not surprising that the Potato breeder of the present day, although he has notable successes to his credit, has not succeeded in producing new immune varieties good enough to take the place of Duke of York, British Queen, King Edward, Up-to-Date or Arran Chief. Great Potatos, like great men, come not singly and often, but rarely and in little groups. If the test of greatness is complicated the groups will be rarer and smaller. Why, therefore, complicate the test? Why, in other words, should the breeder bother himself about Wart Disease? Let him aim at producing the best yielding and best quality Potato. There are nearly two-and-a-half million acres of land eagerly awaiting the advent of new varieties of excellence surpassing that of the best of existing varieties. In the infinite sea of novelty there are fresh and better fish to be caught than those netted hitherto. Why throw back those which do not satisfy an unnecessarily exacting test? Our Potato breeders are seizing the shadow and rejecting the substance. There are only one hundred thousand acres of land scheduled as infected under the Wart Disease Order, that is, one-twenty-fifth of the area not scheduled. Why devote effort so exclusively to the discovery of new varieties suitable for the hundred thousand acres, instead of finding new varieties which will increase yields and profits in that large area of Potato land in which Wart Disease appears to exercise no menace? After all, Wart Disease, even as a bogey, is out of date—like guys on November 5. The maladies to make modern Potato flesh creep are not Wart, but Virus diseases. We agree, therefore, with Mr. Cuthbertson, and hope that Potato breeders will, as it were, let ill alone, and devote their energies primarily to the task of raising varieties of high yield and quality. If they do that it is certain that the future of the Potato in this country will be as rosy as has been its past, and that notwithstanding the excursions and alarms which are bound to flutter our hearts as new diseases are discovered or old ones develop a new, albeit evanescent, viciousness.

Captain F. Kingdon Ward.—Captain Kingdon Ward has reached Madras on his way to Rangoon en route for the Shan Plateau, preparatory to commencing his expedition in a mountainous and hitherto unexplored region of Indo-China. The party will be made up of Colonel Theodore Roosevelt, Mr. Kermit Roosevelt, Mr. S. Cutting, Mr. Stevens and Captain Kingdon Ward.

The Prince of Wales in Covent Garden Market.—The Prince of Wales visited Covent Garden Market in the early morning of Friday, March 22, and spent a busy hour-and-a-half inspecting the various stalls and chatting with the numerous salesmen, asking many questions concerning the origin and destination of the flowers and fruits. He was particularly interested in the flowers from the Scilly Islands, where he has an experimental farm, and in the various fruits from the Colonies. His Royal Highness visited Messrs. George Monro's establishment, and also spent some minutes talking to Mrs. Garcia, the only retail florist with a stall in the market. The Prince arrived at the Market at 7 a.m., and left just before 8.30 a.m., so that he was able to see the market at its busiest time.

Memorials in London Parks.—At the meeting of the London County Council on Tuesday, March 19, the subject was discussed of a memorial to the late Lord Hambleden, which is to be placed in Lincoln's Inn Fields, a small open space in Holborn. Considerable criticism was forthcoming from certain members of the Council and it was stated that the Parks and Open Spaces Committee had at one time refused to sanction the erection of the memorial on the ground that the space, which is only seven acres in extent, and already fully occupied in various ways, is too small to accommodate it. It was argued that there were already too many memorials in the London Parks, and many of the smaller spaces were seriously encumbered with them. It was finally decided to allow the matter to proceed, on the grounds that it would be ungracious to refuse it at so late a stage, and in view of the generosity, especially to the London hospitals, of the late Lord Hambleden.

Carnations Registered with the American Carnation Society, 1928.—Three Carnation novelties were registered with the American Carnation Society during the year 1928, namely, Dandy, Pink Abundage and Spectrum Supreme. Dandy, registered by Messrs. Roman J. Irwin, Inc., New York City, is a sport from Morning Glow; it is rose-pink in colour, and similar in size and general description to Morning Glow. Pink Abundage is described as a seedling from Natalie, with bright rose-pink flowers three inches to three-and-a-half inches across; it is free and continuous flowering, the blooms being borne on long, stiff stems; registered by Messrs. Baur-Stienkemp and Co., Indianopolis. Spectrum Supreme is a dark scarlet sport from Spectrum and is in habit and size similar to it; it was introduced by Mr. George E. Buxton, Nashua, N.H.

More Land in the Lake District acquired by the National Trust.—Through the generosity of Mr. F. J. Hayes, of High Wray, near Hawkshead, a further addition has been made to the properties of the National Trust in the Lake District. This recent acquisition, the gift of Mr. Wray, is the promontory on Lake Windermere known as Bee Holme, situated on the Lancashire shore at the northern end of the lake, not far from Wray Castle. The promontory embraces about three acres of wooded land, and is an island for nine months of the year. Another recent gift of property in this district to the National Trust is that of Cockley Beck Farm, at the head of Duddon Valley, by Mr. and Mrs. E. D. Simon, who purchased it recently and presented it to the Trust with a view to preserving this exceptionally beautiful area, which lies at the foot of Hardknott Pass, in its present unspoiled condition. The property will remain as a farm, but will not be developed in any manner that will spoil its attractiveness.

The "Rose Annual," 1929.—Those who are fortunate in possessing the whole series of *Rose Annuals* published by the National Rose Society have now a goodly library of practical and scientific information concerning the Rose, in addition to Rose history, Rose poetry, Rose aesthetics, and illustrations of Roses and Rose gardens. The newest issue, for 1929, is as admirable as any of its forerunners, and is a further indication of the vast popularity of the Rose and the immense amount of interest taken in its cultivation. The enthusiasm of a keen Rosarian is unbounded; it is reflected in his conversation and in his desire to "tell the world" of his successes and his failures. This enthusiasm is very obvious in the *Rose Annual*, 1929, for the issue is largely devoted to the papers read at the International Rose Conference held at Westminster in July last. The report of the proceedings opens with fundamentals, *i.e.*, Mr. Osborn's observations on "Rose Species," followed by Major Hurst's very able discussion on the "Genetics of the Rose," wherein he points out that "chromosomes carry the Mendelian factors, or *genes* as we now call them, which differentiate the various characters of the Rose." Mr. H. R. Darlington, greatly daring, deals with "The Future of the Rose," and makes a strong appeal for fragrance, but expresses the belief that "the fragrance of the Rose to-day is greater and not less than the Rose of our fathers." In "The Future of the Rose as a Decorative Flower," Mr. G. M. Taylor gives remarkable figures, from Mr. G. Monro, to show the tremendous increase in the production of cut Roses for market during the past ten years. Then follow excellent articles on the "Diseases of the Rose," by Mr. John Ramsbottom; "Colour in the Rose Garden," by Mrs. H. R. Darlington; "Roses as Cut Blooms," by Mrs. F. A. Simonds; and a symposium of "Twenty-four Roses for General Garden Cultivation," arranged by Mr. Darlington as the result of voting by members. Mr. Herbert Cowley writes pleasantly of "The Rose Gardens of Bulgaria." A brief account (with illustrations) of the Society's trial grounds at Hayward's Heath—adjoining Messrs. Charlesworth and Co.'s Orchid nurseries—will prove, to many, to be one of the most interesting items in a most interesting publication. There are reports of the Rose shows of 1928, descriptions of new Roses, and many other interesting items in the three hundred pages, while the text is brightened by scores of half-tone blocks and sixteen full-page illustrations in colour, chiefly of new Roses.

Clivia Ursula.—We are informed that a clerical error occurred in the entry of this Clivia for the consideration of the Royal Horticultural Society's Floral Committee on March 12. The exhibitor was the Rt. Hon. Robert James, St. Nicholas, Richmond, Yorkshire, and not Mrs. R. James, as stated on p. 212.

American Expedition to the Orient.—We learn that a two-year expedition to the Orient, with the primary object of studying Soy Bean culture, has been undertaken by Mr. P. H. Dorsett and Mr. W. J. Morse, of the United States Department of Agriculture. The main object of the exploration will be to study methods of Soy Bean culture in Japan, Chosen, Manchuria and Java, and to seek varieties not at present cultivated in America; varieties of the Persimmon will also be collected, several Japanese and Chinese varieties of this fruit already being in cultivation in the southern States and California; it is also hoped that a better rootstock for the Persimmon than that at present employed in America, will be obtained. Besides the two crops mentioned above, the explorer's will hunt for drought and cold resistant shrubs and trees in Manchuria and northern Japan, and for Leguminous crops for green manure and forage purposes.

Legacies to Gardeners.—The late Mr. Edmund de Quincey Quincey, of Oakwood, Chislehurst, who died on January 26, left £200 to his gardener, Mr. George Lees.—The late Mr. William Martin Stoffell, of Fairfield, Newbridge Weston, Bath, who died on January 12, left £50 to his gardener, Mr. Herbert Thomas George, if still in his service and not under notice.

British Mycological Society's Spring Foray.—The 1929 Spring Foray will be held at Petersfield during the Whitsun week-end. Accommodation is very limited, and members wishing to attend are advised to book their rooms at once. Terms have been arranged as follows, exclusive of afternoon tea:—Lyndum House, High Street, 13s. 6d. per day; The Old College Residential Hotel, 10s. 6d. per day; and Terry's Private Hotel (Temperance), 9s. per day. Application should in each case be made to the Proprietress, stating whether single or double rooms are required. The number of single rooms is everywhere very limited, but most of the larger rooms have two beds. A room at the Old College has been secured for use as headquarters, but this hotel cannot take many members, hence early application is necessary for those who do not want the short walk from the other hotels. The following excursions have been arranged provisionally:—Saturday, May 18: Harting Combe and district around, starting 10 a.m.; Monday, May 20: Up Park and Hemner Hill, working back at base of Downs towards Petersfield; Sunday excursions will be planned according to weather, number present, etc. It would be of assistance if members intending to take part in the Foray would advise the Secretary, Miss E. M. Wakefield, Herbarium, Royal Botanic Gardens, Kew, so soon as possible, and state if they have any papers or exhibits for evening meetings.

Mr. W. E. Shewell-Cooper.—Although coming from a family whose sons have usually been soldiers, Mr. W. E. Shewell-Cooper has devoted his life to peaceful pursuits. Educated at Monkton Combe School, near Bath, and at the Diocesan College, South Africa, he turned his attention to fruit culture and became apprenticed to the business at Mr. C. Van der Bijh's fruit farm at Witte Booman, Constantia, South Africa, where Peaches, Nectarines, Grapes and Loquats are cultivated for export to the British markets. After serving in German South-West Africa during the war, he entered service with Mr. H. M. Cobb, whose extensive fruit farms and market gardens are at Mockbeggar, Higham, Kent. In 1921 he entered Wye College, taking the horticultural course, and the full commercial course, obtaining the National Diploma (I and II) and the prize offered for the most practical man of the year. In 1922, Mr. Shewell-Cooper was appointed Recorder at the East Malling Research Station and later, in the same year, he became Orchard Manager to Messrs. Whiteways at Whimple, Devonshire, where he installed a fruit grader and taught students. In 1923 he served under Mr. H. Dunkin, as Assistant Horticultural Instructor to the Warwickshire County Council, and two years later received the appointment of County Inspector of School Gardens and Assistant Lecturer in Horticulture in Cheshire, with headquarters at the Cheshire School of Agriculture. In 1926 he was appointed Horticultural Superintendent of this School, at Reaseheath—a position he still holds. At Reaseheath, he controls twenty-one acres of horticultural land, a range of eight glasshouses, and four acres of orchards. He has organised trials of early-flowering Chrysanthemums, soil sterilisation, tar distillate washes, and varieties of vegetables, besides arranging demonstrations and courses on fruit bottling, and a Cheshire County Commercial Fruit Show. Articles by Mr. Shewell-Cooper, and reports of his trials, have appeared in these pages during the last few years. Mr. Shewell-Cooper has written many leaflets on horticultural subjects, is a bee-keeping expert, a member of numerous county associations, and is the South Cheshire District Commissioner of the Boy Scouts organisation.

MR. W. E. SHEWELL-COOPER.

Spartium Townsendii on Canvey Island.—A thousand roots of Spartina Townsendii have been planted on the foreshore of Canvey Island, at the mouth of the Thames, in order to preserve the shore from erosion. This grass, which spreads very rapidly, has been utilised in considerable quantities of late years in land reclamation, and is found to make an excellent foundation upon which permanent pasture land can subsequently be established.

Heath Fires near London.—A heath fire held up the golf on Sunday, March 24, on the Downe Golf Links, near Bromley, Kent, and the golfers and villagers assisted the firemen in their efforts to put out the flames. There was also a serious outbreak of fire on Hayes Common the same afternoon, in the subduing of which the firemen were helped by motorists and members of pic-nic parties. A call was also received from Pett's Wood, Chislehurst, the trees and shrubs in which were ablaze over a large area. Fires were also reported at Grove Park, near Bromley, Barnes Common, and Charnwood Forest, near Coalville; at the last-named some twenty acres of Gorse and woodland were involved.

The Shortage of Rain.—The very light rainfall of the last three months is creating a little anxiety in agricultural and horticultural circles, as although, at present, a deficiency of water in the soil is not noticeable, it is felt that unless heavy rainfall is experienced within the next few weeks, the crops of the coming season may be seriously affected, owing to the early drying-up of the springs.

An Einstein Forest in Palestine.—To commemorate the fiftieth birthday of Professor A. Einstein, which occurred on March 14, the Zionists are to plant a forest near Jerusalem which will be named after him. In Berlin, Professor Einstein's services to science were recognised on the occasion of his birthday by the presentation of a life tenancy of a beautifully situated mansion, while the University of Paris conferred an honorary degree upon him

London Daffodil Show.—The Royal Horticultural Society's Narcissus and Tulip Committee decided, on Tuesday, to postpone the London Daffodil Show from April 9 and 10 until April 16 and 17. The show will be held in the old hall, Vincent Square.

Trials of Early Culinary Peas.—With a view to ascertaining earliness of cropping, weight of crop, and general suitability, trials of culinary Peas were conducted last year by the Agricultural Department of the Education Committee of the Leicestershire County Council. The varieties grown were Little Marvel, Marvellous, English Wonder, Hundredfold, Peter Pan, Lincoln, Progress, Pioneer, Sherwood, Laxtonian, Superb and Pilot. The ground in which the Peas were grown was on the light side; a Mustard crop had been ploughed in the autumn previous, and before harrowing, a dressing of half-a-hundredweight of sulphate of ammonia, four hundredweights of superphosphate, and one hundredweight of muriate of potash per acre, was applied. Three rows, each fifty feet long, of each variety, were sown on March 19, the rows being two feet six inches apart. The majority of the pods of each variety were allowed to develop fully before being picked, all the marketable pods of each variety being gathered at one picking, although it is doubtful whether this was wise from an economical point of view, as many pods were only commencing to fill when others were fully developed; in several cases the first picking could have been made several days earlier. It is stated in the report of these trials that with a variety like Pilot there would be little advantage in more than one picking, as the bulk of the crop matures at once, but with sorts such as Peter Pan, Pioneer, and Lincoln especially, a greater weight of crop would be obtained if the pickings were extended to two or three. Pilot was the first variety picked; it is regarded as a good cropper, but its yellowish-green pods are stated to be not very attractive. Little Marvel was second; its pods are small but well filled and produced in pairs, the one fault being they are blunt and difficult to open.

Next, in order of maturing, was Hundredfold, a good all-round early sort, and this was followed by Peter Pan and Pioneer, both good croppers, the latter possibly the better of the two; Progress, Superb, Laxtonian, English Wonder, Sherwood, Marvellous and Lincoln, the last-named being picked about three weeks after Pilot; it is regarded as too late in maturing for early work. Hundredfold, Progress and Lincoln gave the heaviest crops of pods, while Pioneer gave the heaviest weight of shelled Peas from 4 lbs. of pods, Marvellous and Superb being second and third, respectively.

Filming the London Royal Parks.—We learn that the Commissioner of Works has granted permission to a filming corporation to take Cinematograph pictures in colour, of the London Royal Parks. Hitherto permission has not been allowed, but now the ban has been lifted no doubt many cinematograph firms will take advantage of this opportunity of securing pictures which will show the world how beautiful are our London parks.

Welsh Playing Fields Scheme.—Work for many of the unemployed miners in the Rhondda Valley may materialise if the scheme for the conversion of various sites in the Rhondda area into playing fields, as proposed by the Rhondda Area Council of the National Playing Fields Association, is adopted. About sixty-six acres of land have been scheduled for the purpose, and the estimated cost of laying this land out as playing fields is £45,000. Of this sum it is hoped the Ministry of Labour will provide seventy-five per cent., and the Miners' Welfare and the Coalfields Distress Funds the remaining twenty-five per cent. Of the estimated cost of £45,000, the sum of £29,000 is included for wages.

A Colonial Agricultural Service.—Following the recommendations of the Committee set up to consider the organisation of a Colonial Agricultural Service, and of the Colonial Veterinary Services Committee, the Secretary of State for the Colonies has appointed a Colonial Advisory Council of Agriculture and Animal Health. Mr. W. Ormsby-Gore, M.P., is the temporary Chairman of the Council, and Mr. F. A. Stockdale, C.B.E., Assistant Agricultural Advisor to the Secretary of State, is the Vice-Chairman. Those that have accepted the Secretary of State's invitation to serve on the Council are:—Lieut.-Gen. Sir William Furze, K.C.B., Dr. A. W. Hill, F.R.S., Dr. G.K. Marshall, F.R.S., Dr. E. J. Butler, F.R.S., Professor T. B. Wood, F.R.S., Dr. W. H. Andrews, M.R.C.V.S., Dr. A. T. Stanton, C.M.G., and Mr. R. V. Vernon, C.B. The Lawes Trust Committee and the Joint Committee on Research in Animal Nutrition of the University of Aberdeen and the North of Scotland College of Agriculture, have been asked to give their consent to Sir John Russell, F.R.S., and Dr. J. B. Orr, D.Sc., serving on the Council. The Secretary of the Council is Mr. G. H. Creasy, of the Colonial Office.

A Revolving Greenhouse.—A unique greenhouse which, by being revolved, will allow the plants in it to be exposed to the sun throughout its course, has been patented in the United States of America by Mr. Albert C. Burrage, the President of the Massachusetts Horticultural Society. Mr. Burrage has erected one at his home, Orchidvale, Beverley Farms, Massachusetts, his intention in designing it being to hasten the growing of his hybrid Orchid seedlings, although it is considered useful for the growing of other seedlings, especially of sun- and heat-loving plants such as Tomatos, Cucumbers and Melons. Whether it is a practicable proposition or not is questionable. Mr. Burrage's structure is twelve feet square, and is balanced over a cistern ten feet in diameter; the roof is fitted with shelves which are stated to be capable of holding 10,000 seedlings, each in a one-inch pot. The wall of the cement well, which is kept partially filled with water, is covered with a thin, iron, channelled plate, the channel containing two-inch steel balls throughout; a corresponding iron plate, the channel of which fits over the steel balls, is fixed to the bottom of the greenhouse portion. The floor of the house consists of central open grating over the well, and cement round the sides; the framework is of iron and heating pipes pass over the water beneath the floor; the house is also fitted with roller blinds. By means of the ball-bearing fitting, the whole superstructure can be rotated easily. Mr. Burrage has written to each of the many horticultural societies of which he is a member, granting to each member of them a free license to build this patented greenhouse for his own use. Mr. Burrage is a member of the Royal Horticultural Society and The Orchid Club in this country. It is interesting to note that, so far as can be ascertained by a search through the records of America and Europe, no revolving glass greenhouse has ever been built previous to this one designed by Mr. Burrage.

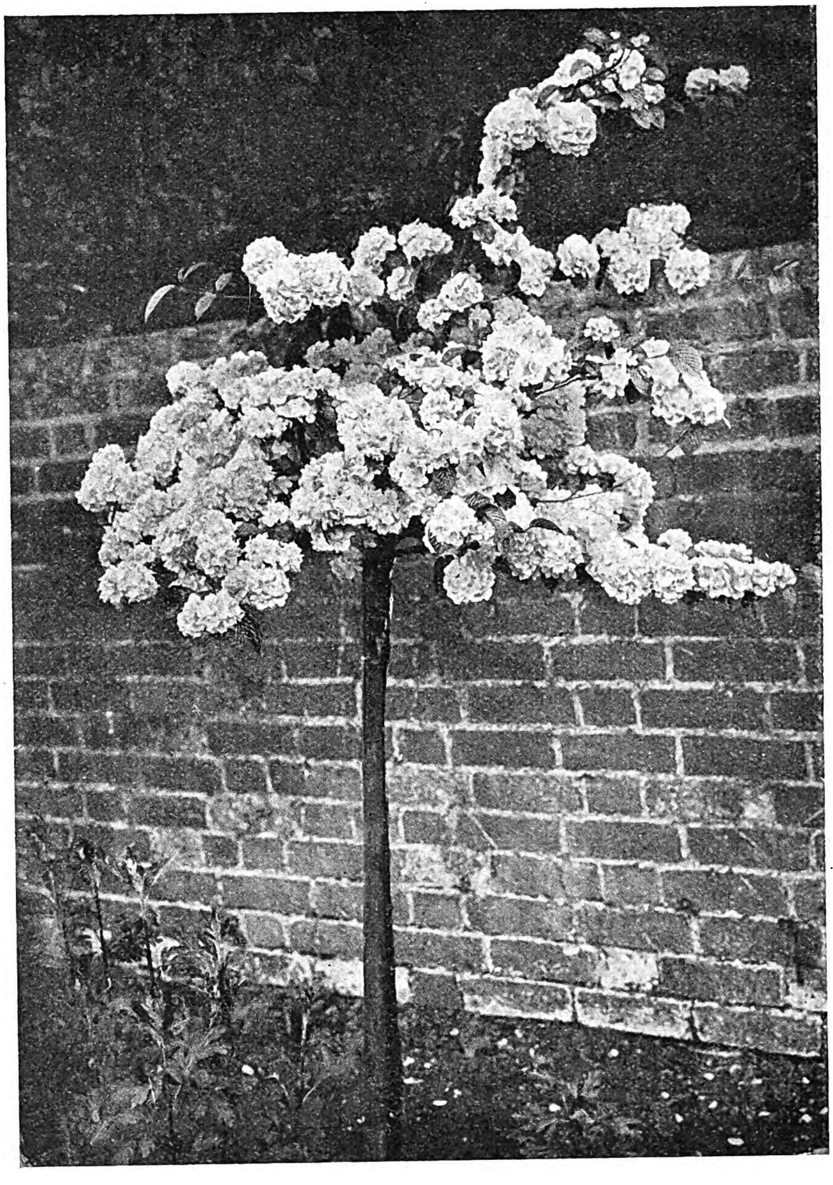

FIG. 115.—VIBURNUM TOMENTOSUM VAR. PLICATUM AS A STANDARD TREE.

(see p. 240).

Appointments for the Ensuing Week.—TUESDAY, APRIL 2: Royal Caledonian Horticultural Society's meeting. WEDNESDAY, APRIL 3: Instow Spring Flower Show; National Carnation and Picotee Society's Show; Wimbledon and District Gardeners' Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting; North of England Horticultural Society's Spring Show (two days). THURSDAY, APRIL 4: Bideford and District Horticultural Society's meeting. FRIDAY, APRIL 5: Manchester and North of England Orchid Societys' exhibition; Dundee Horticultural Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Grape-growing.*—I send you a list of the weight of Grapes cut in an old lean-to house here during the last four years. I may say that for years there were not 12 lbs. of good Grapes cut in it; and as it has been brought to its present state of fruitfulness by following the directions given in your paper, I think it right to give it publicity. The house is thirty-six feet long, eleven deep and thirteen high—no other fruit in it except Grapes, which are principally Black Hamburgh, and trained on the rod principle. Last year was the first year there was any fruit on the back trellis, the vines having been only planted on it the year before. The produce was as follows, all carefully weighed, and good weight given:—128 lbs., 1850; 158 lbs., 1851; 201 lbs., 1852; 234 lbs., 1853. *E. F. L. Donaghadee, Co. Down. Gard. Chron., April* 1, 1854.

Publication Received.—*Starting Early Vegetable and Flowering Plants under Glass*, by Charles H. Nissley. 302 pp. with illustrations; The Orange Judd Publishing Company, Inc., New York. Price $3.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Mexican Laelias.—The members of this gracefully flowered group of late autumn and winter flowering Orchids, among them being L. anceps and its numerous varieties, L. Gouldiana, L. albida L. rubescens, L. autumnalis and L. superbiens, have been resting, after flowering, in a cool, airy position and are now showing signs of renewed activity at the roots; being sun-loving Orchids, the increased sunlight will prove beneficial and bunches of new roots will be produced from the base of the last-made pseudo-bulb. Any plants that require fresh rooting material should receive attention. This is best done so soon as possible at this stage to avoid injury to the fleshy roots, which often occurs if the operation is left until the plants are in active growth at a later date. Annual root disturbance is not advisable, and unless the plants have overgrown their receptacles, or are overcrowded and impoverished, they need not be disturbed; under such conditions all that is necessary is to remove any sour soil and replace it with fresh compost consisting of Osmunda fibre and a little Sphagnum-moss, inserted firmly among the old roots. Where repotting is necessary, the plants should be turned out carefully and all old compost and decayed roots and pseudo-bulbs removed, retaining two or three sound pseudo-bulbs to each lead, which may be potted separately, or several arranged together to form a compact specimen. Baskets or pans are the best receptacles, and the Osmunda fibre should be used in a fairly coarse state, with some chopped Sphagnum-moss added, together with some lump charcoal to keep it open. Firm potting is essential. Very little water is required until the roots are well established in the fresh compost, and the plants will thrive if suspended in a light position in the intermediate house, and sprayed lightly on favourable occasions to encourage root action. Any shading should be removed early in the afternoon, and the plants and surroundings well syringed with tepid water while the temperature is rising. A free circulation of air should be allowed on all favourable occasions, especially at night.

Seedling Dendrobiums.—With the increase of sunheat, the small seedling Dendrobiums are growing well and new roots are being produced. Those plants requiring a larger pot or fresh rooting material, consisting of three parts Osmunda fibre and one part moss, should be attended to forthwith. Quite small receptacles may be used for these seedlings, which should be grown in a light position in the warmest house, where humid surroundings are maintained, and as the roots and growths advance the compost should not be allowed to remain dry for long periods, especially during bright weather. The bulbs should be supported, and every encouragement given to assist the plants to grow freely. Light shade should be given from very strong, direct sunshine, to prevent the foliage from being scorched.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Melons.—Unless fermenting material has played an important part in maintaining bottom-heat and atmospheric moisture, cold nights and absence of sun have rendered the employment of fire-heat absolutely necessary. The Melon plants have not made the progress they should have done, and great care will have to be taken to prevent red spider attacking them. If previous directions have been carried out, the final top-dressing of Melon plants in pots or borders should be performed when the fruits are the size of chicken's eggs. Feeding from this stage onward must be on a liberal scale until the fruits attain full size, and the more frequent the change of food the better the progress and the finer the fruits. The night temperature should range about 70°, and by day 80° to 85°, and 90° to 95° after closing, should be aimed at. Advantage should be taken of sun-heat, and moist conditions maintained. Remove all useless spray, and preserve all premier leaves, and pinch the lateral growths at the first joint after the fruit. Follow previous instructions with succession plants. Day and night temperatures may be increased on bright, sunny days when air may be admitted. When in free growth the plants require liberal supplies of tepid water, stimulants being reserved for the swelling of the fruits. Top-dressings with compost previously warmed should be applied as the roots appear on the surface. Where Melons are grown in pits heated with fermenting manure, now is a good time to commence operations. Fresh stable litter and equal parts of Oak and Beech leaves should be well mixed together and turned two or three times before making up the beds. Sow the seeds in small pots, and by the time the plants are ready, violent heat will have subsided and the ridges of compost will have become thoroughly warmed through, when planting may be carried out. Rich, or too light soils, should be avoided, or strong growth may follow and few fruits will be produced. Melons cannot have too much light and sun-heat. Two plants to a light is sufficient. Place more compost firmly around the plants as growth advances and the roots appear. With this treatment, ripe Melons should be obtained in about fifteen weeks.

Melons in Frames.—These do not require one-fourth of the soil frequently given to them; it is a good plan to place two rough boards a foot or more in width on their edges, and about eighteen inches apart, in which to place the top-dressing material. Covering with dry mats every night at this early season is of great assistance, and cold water should never be used to damp either the foliage or the surface of the bed. Any damping or sprinkling necessary should be done early on bright, warm days; this requires some judgment, and unless the heat can be maintained it should be omitted.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Gladioli.—Gladioli require a smaller amount of attention than many flowering plants, and by planting the corms at frequent intervals from March to May, the season of these useful flowers may be extended considerably, while there is such a wide range of colours and types that a useful selection may be made for any purpose. The principal requirements are a well-drained, deeply-dug, fairly rich soil, and an open, sunny position. The corms of the large-flowered varieties should not be planted at less than one foot apart, and the more slender forms of G. primulinus may be spaced about nine inches. The depth of planting will depend on the nature of the soil, three inches being deep enough in heavy soils and from four to five inches in those of a light nature. If the soil is heavy and retentive, it is advisable to place a little rough grit or sharp sand under and around each corm. Where Gladioli are to be used in conjunction with summer bedding plants and cannot be planted in their flowering quarters until the spring bedding display is past, the corms should be potted singly into five- or six-inch pots during April, and if stood in the open, they should make ideal specimens for furnishing the flower garden at bedding-out time. With their sword-like leaves they are admirably suited for bold grouping in the mixed border. The choice of varieties and sections is a matter of individual taste, and the purpose they are required for. For massing, the bolder flowers of the gandavensis hybrids are much sought after, but for flowers of refinement none compare with those of the primulinus group, whose charming, hooded flowers may now be had in a wide range of colours.

Violas.—The Violas that have been in cold frames all the winter may now be placed in their flowering quarters. These useful bedding plants like a position where they are partially shaded from the midday sun, and under such conditions the period of flowering is lengthened considerably.

Spiraeas.—The shrubby Spiraeas that bloom in summer may be pruned fairly hard to keep them dwarf and to encourage the production of a plentiful supply of vigorous young shoots which will flower freely. Such sorts as S. japonica, S. japonica var. Anthony Waterer, S. j. Bumalda, S. Douglasii, and several others, are included in this group.

Pruning Newly-planted Roses.—Newly-planted Roses should be pruned very hard the first season, irrespective of the group they belong to. Unless this is done there is apt to be a long bare gap between the ground and the first break. The object of this hard pruning is to encourage the production of strong, basal shoots, so that a good foundation is made to build up shapely bushes in the future.

Pruning Rose Species—Rose species require little pruning, the removal of weak, and old, worn-out wood being all that is required. This may be attended to now if not already done, but it is usual to thin the growths immediately after flowering or during the winter.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—These have suffered very badly owing to the severe and prolonged frosts of February, when we registered 25° and 27° on the 14th and 15th, respectively. Many crowns have succumbed completely, especially those that were partly exposed above the soil. Those that were well moulded up with soil last autumn have not suffered so severely. I notice, too, that the variety Royal Sovereign appears to have suffered less than the varieties King George and The Duke. The soil is working wonderfully well, and the first opportunity should be taken to draw up a little of the finest mould around the basal leaves, to encourage the production of adventitious roots. Where young plants have been raised out of the ground by the frost, they should be pressed in again by hand, and every possible attention afforded them this spring if they are to pull through.

General Work.—Examine autumn and more recently planted fruit trees, treading well around any that may have been loosened by wind or frost, and see that no stake or support is injuring the bark of the tree. It is not too late to prune established trees, but the sooner this work is completed the better. In the light of modern research, late pruning is considered advantageous because cuts made in late spring heal up much more rapidly than early ones, and on leader growths more lateral buds develop than is the case when the pruning is carried out in the depth of winter. With Apple and Pear trees planted last autumn or early winter, the leader growths should not be pruned until the sap is flowing freely, when they should be cut hard back to dormant buds. The weather has been ideal for the destruction of weeds in the fruit quarters, especially where the soil had been moved just prior to the hard spell. The soil is crumbling at the least touch, making it much more easy to fork out Couch and other pernicious weeds. In working among some Gooseberry bushes this week, I found the larvae of the magpie moth, apparently quite uninjured by the recent severe frost; and later I was shown the larvae of the Cabbage moth. This shows the powers of endurance possessed by these grubs in winter. In making a general survey of our fruit trees, there is every reason to anticipate heavy crops of most fruits this year, the exception being Strawberries, which are distinctly poor. Apples and Pears are very promising, as also are Plums. The blossoming period for Plums, which is usually round about March 20, will be quite a fortnight to three weeks later this year. This is all to the good. Raspberries and Black Currants are looking particularly well and clean. Gooseberries and Red Currants, where they have been left unprotected by black cotton, have suffered badly from attack by tits and sparrows. In some cases the birds have stripped the bushes of almost every bud. I have never known the meshwork of black cotton to fail and it has been given a good test here this season.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain,
Brocket Hall, Hertfordshire.

Chrysanthemums.—The young plants that were raised early from cuttings and are being grown to produce large exhibition blooms should now be ready for potting into thirty-two-sized pots. The compost for this potting may consist chiefly of good fibrous loam, to which may be added short manure—that from a spent Mushroom-bed being suitable—bone-meal, wood ash and coarse sand, with a dusting of an approved fertiliser. The compost should be thoroughly mixed by turning several times, and it should be in suitable condition to allow of fairly firm potting. The plants, when potted, may then be stood in a cold frame, allowing plenty of space between each plant; the frames should be kept close for a few days to assist the plants to establish themselves, after which air may be admitted freely on all suitable occasions, removing the lights entirely on fine, mild days. Give good soakings of clear water when required. On cold nights they will need covering with mats or other protecting material. When preparing the compost it is advisable to mix sufficient for this and the final potting. This will save time, and the compost will be in better condition if prepared in advance. There are certain varieties of Chrysanthemums that require stopping next month in order to secure the buds at the proper time to obtain large exhibition flowers; among these sorts are Queen Mary, Princess Mary and Victory. These may have their tops removed about the third week in April. Majestic and its sports, Mrs. G. Drabble and William Rigby, should be stopped during the second week in May; these dates are those which I go by to obtain exhibition flowers for the second week in November, securing the first buds from the breaks. Another means of obtaining good exhibition Chrysanthemum flowers is to root the cuttings about the second week in April in a cold frame, and grow them on single stems in six- or seven-inch pots, securing the first buds; grown in this form they are excellent for grouping purposes.

The Conservatory.—At this season of the year an abundance of material is available for the decoration of the conservatory. With the lengthening days the sun is gaining more power, and shading should be practised during periods of bright sunshine.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Peas.—Another sowing of Peas may be made to maintain a succession. Pea seedlings just above ground should have sticks placed to them; the sticks shelter them from wind and frost at this stage. Gradus and Duke of Albany are two suitable sorts to sow now, and these do well in most districts.

Turnips.—Early Snowball Turnips may be sown now in the open in a warm position. Any Turnips still in the ground should be lifted and placed in ashes and the ground dug in preparation for another crop.

Spinach.—A further sowing of Spinach may be made, and when the seedlings are well advanced thin them carefully. If plenty of space is allowed between the plants much finer leaves will be produced than if they are allowed to become crowded.

Celery.—The seedlings from seeds sown some few weeks ago for early work will now be ready for pricking off into boxes or three-inch pots, in a compost of good loam, leaf-mould and a little sand. Grow them on in a steady temperature, spraying the young plants overhead and never allowing them to become dry at the roots, or this will cripple their growth. Celeriac may be treated in the same manner.

Carrots.—Seeds of Long Red Surrey and James' Intermediate Carrots may now be sown in deeply dug soil. Previous to sowing the seeds the soil should be forked well and the surface made fine; if the soil is at all wet it is better to defer this sowing until conditions are suitable. If a dressing of 9 lbs. Sterolena to 112 lbs. of finely-sifted lime, well mixed together, is spread evenly over the ground before it is dug, it will be found beneficial in warding off Carrot root maggot. Sterolena is much safer and more effective in destroying grubs in the soil than sheep dip or paraffin; if exhibition Carrots are grown in specially prepared holes, this preparation may be mixed with the soil with which the holes are filled.

Crops in Frames.—The surface soil of the beds of the various vegetables and salads in frames should be stirred frequently, and on fine days an abundance of fresh air should be afforded; the air should be admitted evenly throughout the frame, pulling up every alternate light and pushing down the others.

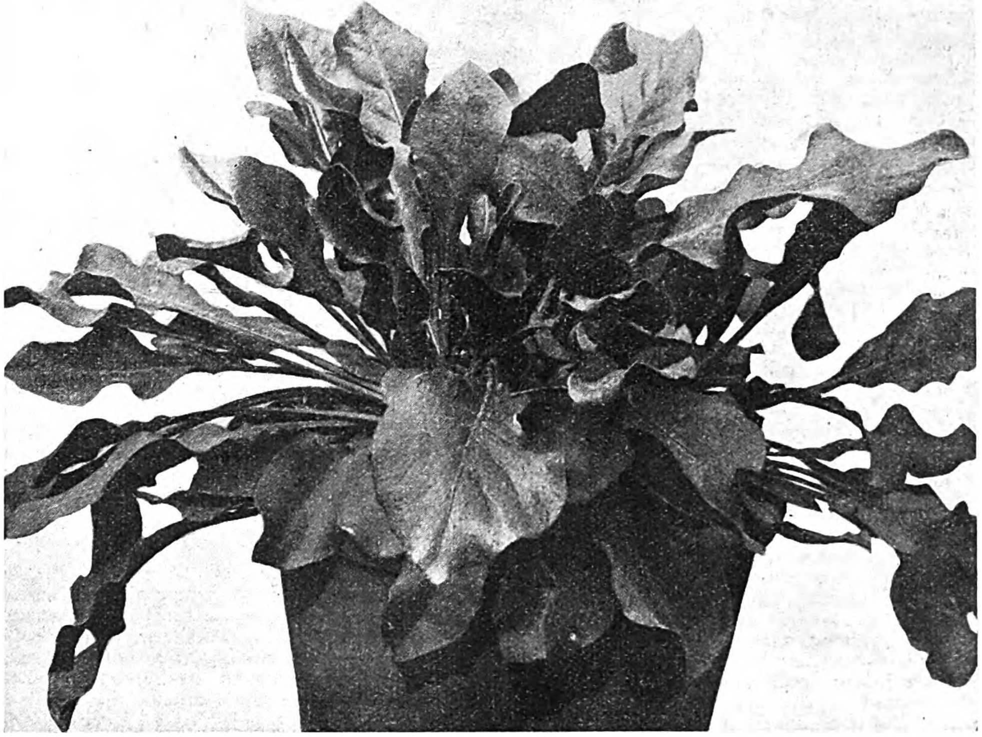

FIG. 116.—STATICE PROFUSA IN A SEVEN-INCH POT.
(see p. 241).

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemount, Monkton, Ayrshire.

Main-crop Celery.—Being one of the most important crops, this deserves special attention. Celery should be grown without a semblance of a check at all stages, or it may run to seed prematurely. Any good red variety may be sown now in light soil, consisting chiefly of leaf-mould and sand, with enough loam to give it body, and placed in heat. After germination remove the seedlings to a cool house or frame, and prick them off when the first rough leaf appears, boxes being the best receptacles. They should be placed in a warm house for a few days to establish them, and then returned to frames. When they have grown together, transplant them into shallow frames, in a bed of soil three inches deep over a good layer of old manure, with a hard ash bottom. Plant the seedlings four inches or so apart, and when they are established remove the lights entirely. Give abundance of water at all times, and a week before planting, run a knife lengthwise and crosswise through the soil between the plants, touching the ash bottom, when they should lift in blocks and feel no check whatever. On heavy or wet soils make the trenches shallow and allow plenty of space between them to afford soil for earthing up. Treat generously as to manure, but over feeding makes the growth soft and hollow, and prevents long keeping.

Peas and Beans—Sowings of these for succession should now be made at intervals of ten or twelve days, and in most localities it is safe to sow wrinkled or Marrowfat Peas early in April. Early sowings should be thicker than usual, but if all the seeds germinate, thinning should be practised.

Winter-flowering Carnations.—If these plants, which have been flowering all the winter, are not responding to the longer days by making satisfactory growth, they should be repotted at once. See that they are thoroughly wetted at the roots a day or so before repotting. The soil should consist of four parts good turfy loam, one part old cow manure in a rather dry state, half-a-part sand, and half-a-part mortar rubble and burnt soil or charcoal, with a dusting of Carnation manure. Turn out the plants, reduce the old ball slightly, or severely in bad cases, and return to the same size pot or a smaller one. Pot them rather firmly, but do not employ a rammer. Shade them from sunshine for a few days and spray them overhead twice a day for a week or so; apply water at the roots only when absolutely necessary.

Autumn-sown Sweet Peas.—If these have been grown quite cool, they should now be planted out, the ground having been previously well prepared and allowed to settle. Short sprays of Spruce or such like should be placed around them, to steady them, and also to afford shelter from cold, cutting winds. If slugs or snails are troublesome, bran, slightly wetted and coloured with Paris green, should be sprinkled, close to, but not on, the plants; this is usually effective in killing the pests, but after heavy rain the application must be repeated if the pests are still troublesome.

LATE PLANTING IN THE PRESENT SEASON.

There is an adage, uttered by sages of old, that "he who plants early may sleep in peace, while he who plants late may be kept awake by the groaning of his plants," and probably no season within the memory of present-day gardeners has given cause for so much groaning, if one may use the metaphor, as the present one. It is an old story that the late planter comes when the nursery quarters have been picked and picked, and the best plants are gone; when the ground has become cold, and frost and snow alternate with dry east winds to stop the work; and when the excitements of spring are near at hand, but winter still reigns to increase the hazard of exposing roots to the atmosphere, and nothing could more emphasise the advantages of autumn planting than the present season.

But, well as the practical gardener realises the advantages of early planting, circumstances nearly always compel him to do some late planting, and in a season like the present one, when planting was impossible for so many weeks, there must of necessity be large arrears of planting to be done this spring in most gardens. Recriminations are thus of no help, and the planter has to face the disadvantages of late planting and study how best to ensure the welfare of the material to be planted, whether shrubs, trees or herbaceous plants. And despite all there may be against late planting, it is sometimes impolitic, even if possible, to complete planting in the early season, for the good, heavy soils in which trees of almost all kinds thrive best are not infrequently so water-logged the whole winter through that planting cannot be done properly until the March dust is blowing, and even this would be preferable to pasting the trees into waterholes, as might be necessary where early planting is insisted on.

With regard to material planted immediately before the adverse weather conditions set in, I see no reason why it should suffer abnormally if it receives attention so soon as the thaw is complete. The up-lifting power of frost is well-known, and the roots of all newly-planted subjects should be thoroughly rammed so soon as soil conditions allow. Frost has penetrated to an unusual depth, however, and the soil should be tested to ensure that the thaw is complete before this ramming is undertaken.

Many gardeners will have received consignments which they were unable to place in position before the frost stopped ground operations, and have kept them in some position of protection awaiting the thaw. These will be in an advantageous position, for ground that was previously prepared for planting has been left by the frost in excellent condition for facilitating the operation, the friable nature of the surface soil making it easy to lay the roots out and cover them to the best advantage, but thorough consolidation and secure staking of large trees, to prevent any possible "pulling" of the roots, are essential factors to success.

Those who have to wait for the delivery of their plants from the nurseryman are less advantageously placed, but the position is not hopeless. The calendar is not the governing factor in planting, and one season may see growth so far advanced at the beginning of March as it is at the end of that month in another season, thus the retarding effect of the long period of frost, and the fact that, except for a "fleeting heat-wave," the average temperature since the thaw has been relatively low, have resulted in extending the time for successful planting.

Even after all the factors governing good planting have been observed, the mortality among late planted subjects is generally greater than that among early-planted ones, but the most potent cause of loss is lack of moisture at the roots just as new rootlets are being emitted. Thus it appears to be more than ever necessary after planting is completed this spring to study rainfall, and should we get a period of drought, to see that recently-planted subjects are assisted with copious waterings and, wherever practicable are mulched to conserve moisture. Another old writer stated that trees planted before Christmas will grow without being looked after, but those planted between Christmas and Lady Day must be coaxed to grow, while those planted after the latter day must actually be compelled to grow. There may be an element of truth in this, but the planter who has observed every good rule of planting, except the date, will not fail to give his subjects the necessary after-attention to compel them to grow. *W. Auton.*

TREES AND SHRUBS.

HELIANTHEMUM UMBELLATUM.

It has been very gratifying to find that all old specimens of this charming Sun Rose survived the recent frost, which is the more remarkable when it is realised that most of them were in active growth when the hard weather came along. The budded tips were, of course, cut back, but this is a trifling matter compared with the havoc among allied species and garden hybrids.

H. umbellatum is one of the most delightful and distinctive of its race. It is a loose-habited, semi-procumbent little bush of about eighteen inches in height and two to three feet across. The dark green foliage rather suggests that of Rosemary, with the result that it is still often listed as H. rosmarinifolium, a name belonging to another species. The flowers, borne in terminal, erect racemes, are white with a yellow stain at the base of the petals. They are not so large as those of most Sun Roses, but are produced in great abundance in spring and early summer and, as often as not, in autumn. In fact, there are very few months of the year in which H. umbellatum is entirely without some blossom, and the firm, pure-white of the cup-shaped blooms has a telling background in the deep green foliage.

This Sun Rose is a native of southern Europe, and has been in cultivation here for nearly two centuries. It is very easily grown in any light, stony soil with full sun, and may be increased by cuttings as readily as any of the rest of its race. I have found this little shrub remarkably permanent, carrying-on without attention for many years and never becoming leggy and ungainly as do so many of its kind.

CISTUS CORBARIENSIS.

This is one of the few Cistuses which have come through the past winter without serious injury. It is said to be a natural hybrid between C. populifolius var. narbonnensis and C. salvifolius. To some extent it partakes of the character of both parents, with a leaning towards the former save in the much smaller size of all its parts. C. corbariensis is a useful Rock Rose for grouping on hot, sunny banks in Heath gardens and such places. It may also be grown in thin woodland, since it does not object to partial shade. Making a well-rounded, rather dense, leafy bush of about three feet in height and four feet across, C. corbariensis is a delightful object when covered with its innumerable flowers. These are borne from June onwards in small clusters, each blossom being one-and-a-half inch across and pure white with a yellow stain at the eye. The ovate, rather pointed leaves, up to two inches long, are a full-toned green and have wavy, slightly-toothed margins. The younger growths are often of a reddish tint, as are those of C. populifolius, this giving the shrub a ruddy, or sunburned, appearance.

I have found C. corbariensis not only very hardy, but a good doer under any average conditions, and regular and abundant flowering. It may not be much, if any, longer-lived than other Cistuses, but it retains a shapely, compact form throughout.

The only trouble that I have ever had with this, as well as with other Rock Roses of its class, is this: It is liable to get loose at the root and to be blown over so soon as there is a good head of growth. This may not occur when the root-hold is rocky, but in any event it is possible to avert such disasters by grouping the plants fairly closely so that they will touch one another when rather more than half-grown. In this way one also gets a better effect, it being the natural habit of most Cistuses to grow in dense colonies. *N. Wales.*

VIBURNUM TOMENTOSUM VAR. PLICATUM.

More commonly known as merely Viburnum plicatum, this beautiful variety of Viburnum tomentosum is one of the most attractive members of the genus, and it probably ranks among the best dozen deciduous flowering shrubs that we have.

The Japanese Snowball Tree, as it is popularly termed, is not uncommon in English gardens, for it is easily grown, quite hardy, and very accommodating, while it responds well to training and is especially handsome when grown as a standard (Fig. 115); it is also grown extensively in conservatories, as it may easily be forced into bloom early and is very effective under such conditions.

The inflorescences of V. t. var. plicatum are composed completely of sterile blooms, a fact responsible for its striking beauty; the crowded inflorescences, pure white and about three inches across, vary from a flattened to almost a globose umbel; they are produced so freely that, in June, the plant is often transformed into a striking, unbroken mass of white. It was introduced from China by Fortune so long ago as 1844, but it is only in comparatively recent times that it has come to the fore as a first-class flowering shrub; no shrub border should be without it, while, when trained as a standard, it makes an ideal specimen plant.

This Viburnum, like the majority of its relatives, may be propagated quite easily by cuttings, and it flourishes in good, deep, loamy soil; it is considered hardier than the type, V. tomentosum. *F.*

ROSE GARDEN.

LATE-FLOWERING ROSES.

One of the charms connected with the Rose is its extensive period of flowerng. It is no uncommon thing to have Roses in bloom from June to Christmas, in fact I have gathered half-a-dozen good-sized buds on New Year's Day. This is remarkable, for my garden is situated in a cold, exposed position on the Derbyshire hills, and Roses that will bloom under the trying conditions here are likely to do the same elsewhere, especially where shelter from cold winds is available.

The plan I usually adopt with late Rose buds is this:—I gather all the buds when they are still hard and open them slightly, but carefully, with the finger and thumb; I then put them in hot water and stand them near a window where they may obtain plenty of light, in a warm room. The buds respond quickly to the light and warmth, and develop in an astonishing manner. In removing the damaged outside petals, some gentle fingering is required, so as not to tear them right off, for if these are completely detached, the inner ones are likely to fall off, too, when the buds begin to open. It is safer to cut the petals away with scissors, leaving the extreme base of the petals as a support to those left.

After many years of experience, I still consider the following Roses are the best for late flowering:—Frau Karl Druschki, will last in bloom until severe weather stops it; A. R. Goodwin is very free-flowering and one of the best Roses in the garden; Lady Roberts is an excellent Rose, although paler in colour than the earlier blooms; Hugh Dickson is rich and free, and one of the best; Mrs. John Laing is a good Rose for keeping its size; Killarney, although often a victim to mildew, is profuse in the production of flowers; Climbing Mrs. Grant produces its large-size blooms freely; Homère, flowers well into December, its blooms being of good size and freely borne; Frau Lilla Rautenstrauch is a charming late Rose with richly-coloured blooms; Mrs. Aaron Ward produces good flowers throughout the season until December; La

France is an excellent Rose in dry weather, but a wet season spoils it, and Lady Ashtown and Caroline Testout are both good late-flowering sorts.

Space will not permit of a large selection of autumn-flowering Roses, but the following are well worth cultivating:—Molly Sharman-Crawford, Ben Cant, Francisca Kruger, Kaiserin, Augusta Victoria, Général Jacqueminot, Madame Lambard, Marie van Houtte, Lady Hillingdon, Madame Abel Chatenay, Lyon, Richmond and Liberty. *A Nurseryman.*

INDOOR PLANTS.

STATICE PROFUSA.

I was interested in the note on the propagation of Statice profusa (p. 193), particularly as I have grown this subject for many years, and have found that ringing forms the best method of increasing stock. An old plant, three years or four years old, will carry from ten to twenty good heads and provide an equal number of good plants if each stem is ringed during March or April and mossed up as shown in Fig. 117. After such treatment roots are made freely, and each head will be ready to be potted into a six-inch pot by the end of the summer. The second illustration (Fig. 116) shows a plant in a seven-inch pot, the result of ringing in April, 1928. Statice profusa is a most useful subject for conservatory decoration and quite easily managed. *Thomas Elder, The Gardens, Old Place, Lindfield, Sussex.*

PERPETUAL-FLOWERING CARNATIONS.

Such rapid strides have been made in the culture of Perpetual-flowering Carnations during the past quarter-of-a-century, that to-day they probably rival the Rose in popularity. Yet, in spite of numerous novelties introduced each year, there are certain of the older varieties that more than hold their own at the present day, both with market growers and in private establishments; of these, May Day, Lady Northcliffe, Mikado, Baroness de Brienen and Enchantress are to be met with everywhere in the Carnation world. Undoubtedly, in a large majority of private establishments certain varieties that find favour with the owners are grown in larger numbers than less favoured sorts, but where quality is the first consideration and the gardener has the opportunity of choosing the varieties to be cultivated, and should he desire to keep his collection up-to-date, he may at times be at a loss to know which varieties to discard to make way for newer introductions.

Of the white-flowered varieties in cultivation, White Pearl is undoubtedly the largest but, unfortunately, it is very slow-growing, although robust and possessing a strong scent; for the latter reason alone it should be in every collection. White Wonder, an older variety, strongly-scented, and the newer Tess, are also worthy of inclusion.

There are many light pink sorts, but pride of place falls to Laddie, a magnificent variety with long, strong stems and a large flower of good substance and perfect calyx, the plant itself being of vigorous growth. Eileen Low is another grand variety, and deserves a place in every collection, while Baroness de Brienen, May Day and Lady Northcliffe are well-known market varieties that cannot be dispensed with, Lady Northcliffe being especially suitable for market and it work as it lasts particularly well when cut, is probably grown more than any other variety.

Of the medium pink sorts, Betty Jane is to be recommended, for it has long, wiry stems and a perfect calyx, and it also flowers well in winter. Hebe is a delightful salmon-coloured sort, strongly scented, with the edges of the petals fimbriated like those of the old favourite Rose Don. Mary Allwood is another popular variety, the colour of its blooms being a cherry-salmon that shows up well in artificial light; its flowers are large, well-shaped and smooth-petalled.

Betty Lou is one of the finest in the deep pink section, its blooms being a rich, deep rose; while Master Michael Stoop is a vigorous grower with large flowers, and Peerless is exceptionally free-flowering and a profitable variety for market work; both these latter have deep rose-pink blooms. Of red varieties there are many, but few approach the much wanted scarlet. Aviator is the brightest yet introduced, but the flowers are hardly large enough for exhibition work, although for its colour and free-flowering qualities it should be in every collection. Tarzan and Spectrum are both large-flowered, brightly-coloured varieties that keep their colour well during the winter, the latter probably being the best red yet in commerce, from an exhibitor's point of view. Red Laddie—a sport from the well-known Laddie—is identical with its parent in all but colour, and for this reason alone should be grown extensively. Bis Greenfield, a variety not listed by most nurserymen, is a grand Carnation of robust habit, with large, bright flowers and a perfect calyx; it suggests a perpetual-flowering Malmaison.

Crimson Perpetual-flowering Carnations are not so numerous, the favourites being Topsy, a delightful dwarf, free-flowering variety, good in every way, and Mrs. A. J. Cobb, with large, well-shaped blooms, that won the *Daily Mail* Gold Cup in 1927 as the best-scented variety. Triumph, an older sort, is still probably the brightest crimson, while Nigger is excellent for market work and is strongly scented. Mikado, despite its age, more than holds its own in the heliotrope section, it being one of the best winter-flowering varieties, with a long, wiry stem and perfect calyx, and very fine "grass," by which it can be distinguished from all other varieties. Unfortunately, Mikado seems rather prone to attacks of rust, more so than any other variety, except, perhaps, Sunstar, Orange Sunstar and Saffron. Mary Pearson is also worthy of inclusion in this section, being an exceptionally strong growing variety with a large flower, delightfully scented. There is still a need for a really good yellow, the nearest approach to pure yellow being Saffron which, however, is occasionally streaked with white. This variety, however, with Maine Sunshine, constitute the best of the yellow section.

Those who find delight in Fancy Carnations have a wide range to select from, the best of the white ground Fancies being Charity and Lady Hindlip; the former is of grand colouring, with a whitish ground, flaked and speckled claret. Lady Hindlip, white, pencilled red, is exceptionally free-flowering all the year round, and should be in every collection. Citron, a citron-yellow sort, with rosy-pink markings, is a delightful 1928 novelty and is worthy of extensive cultivation on account of its unique colouring alone. Sheila Greer, bright yellow ground, striped red, makes an attractive vase and is very free-flowering, while Jazz, with its flowers of light orange, heavily flaked deep pink, is particularly effective in artificial light. Melchet Beauty, heliotrope, with cerise markings, is a delightfully free-growing and sweetly scented sort which flowers well all the year round, and Shot Silk has very attractive colouring, Indian-chestnut, flaked red, but it is, unfortunately, a rather shy grower. Sybil and Queen Mary are two deep violet-purple varieties, quite distinct from any others, which deserve to be grown by all. *A. J. Turner.*

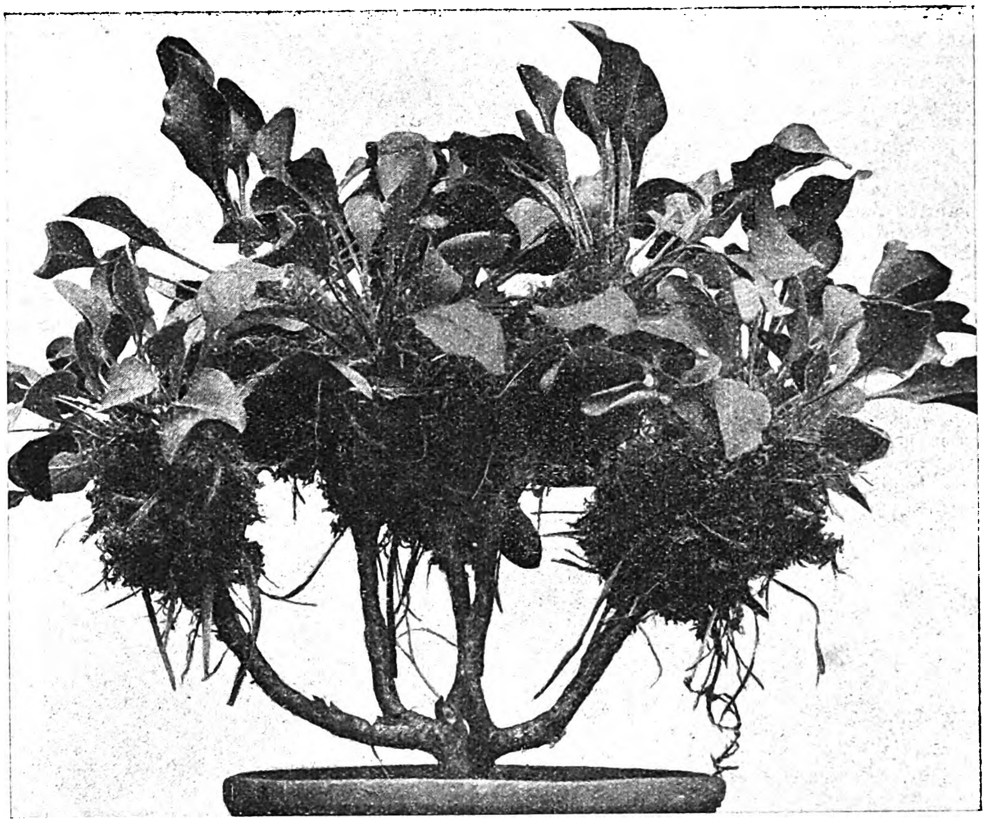

FIG. 117.—STATICE PROFUSA.

A three-year old plant ringed and mossed-up for propagating.

WOODLAND GARDEN.

BORAGO LAXIFLORA.

This is an ideal woodland plant, and one that can be very attractive in the bolder parts of the rock garden or the mixed border. It is essentially a subject for associating with others, and since it naturalises freely without being aggressive, it is eminently adapted for such treatment. I find it a charming thing among hardy Ferns and lowly shrubs, especially in shady corners, for although it is a Corsican it seems to do very well with a minimum amount of sunshine.

B. laxiflora makes a squat basal tuft of broad, bristly leaves, and puts forth all summer and autumn a succession of flowering stems. These are slender and semi-prostrate, finding support among neighbouring plants, and they bear deeply-cleft, bell-shaped flowers of a pale, clear azure-blue. Although not a long-lived species, B. laxiflora sows itself as I have indicated, and in this way it will carry on indefinitely in its own quiet way. It is quite hardy and does well in poor, dry soil, even about the roots of woodland trees. *J.*

PLANTS NEW OR NOTEWORTHY.

FRITILLARIA KARADAGHENSIS.

(See Fig. 107, p. 221).

FRITILLARIA (§TRICHOSTYLEAE) KARADAGHENSIS, TURRILL.

SP. NOV. A *F.* crassifolia, BOISS. ET HUET, FOLIIS ANGUSTIORIBUS RECEDIT.

Bulbus subsphaericus, 1·7 cm. diametro, tunicatus. *Caulis* glaber, teres, usque ad 1·7 dm. altus, inferne saepe purpurascens, supra medium 5-8-foliatus. *Folia* subcrassa, linearia vel oblanceolato-linearia, inferne gradatim superne plus minusve attenuata, 5-7 cm. longa, 4-7 mm. lata, subobtusa, glauco-viridia, siccitate intense viridia. *Flos* saepissime solitarius, tubuloso-campanulatus deinde late campanulatus, perigonii phyllis 2·2 cm. longis luteo-viridibus plus minusve purpurascentibus longitudinaliter viride-striatis supra basin nectario ovato foveolatis externis oblongis 0·95 cm. latis internis obovato-oblongis 1·1 cm. latis. *Filamenta* 8-9 mm. longa, basi dilatata, papilloso-hirtula; antherae indehiscentes 7 mm., dehiscentes 3-4 mm. longae, pallide luteae. *Ovarium* cylindricum, 7 mm. longum, stylo ramis tribus viridibus 4 mm. longis inclusis 6 mm. longo.

Bulbs from the Kara Dagh, North Persia, coll. Egger, cult. in Tabriz, early spring, 1928; Gilliat-Smith No. 2213. Also in flower at the Royal Botanic Gardens, Kew, March, 1929.

This new species has been compared above with F. crassifolia, Boiss. et Huet, a species described in Boissier's *Diagnoses II*, IV., 103 (1859), from Armenia ('in Armeniae collibus agillosis prope *Baibout*, Aucher No. 5376, in lapidosus montis *Techdagh* prope *Erzeroum* Huet. de Pavillon'). Afterwards, in his *Flora Orientalis*, Vol. 183 (1884), Boissier added plants from Asia Minor and from Syria, but these appear not to belong to the same species.

Our species resembles in general habit Fritillaria graeca, Boiss. et Sprun., *Diagnoses I*, VII, 104 (1846), a species restricted to the Balkan Peninsula, and figured in *Botanical Magazine*, t. 5052. It differs, however, in the colour of the flowers and the papillose-hirtulous filaments.

From F. aurea, Schott, in *Oesterr. Bot. Wochenblatt*, IV., 137 (1854), collected by Kotschy in the Taurus range, it differs in the colour and markings of the tepals.—*W. B. Turrill, D.Sc., Kew.*

ALPINE GARDEN.

TIARELLA CORDIFOLIA.

THIS charming member of the Natural Order Saxifragaceae is found throughout a large area of the north-eastern United States, and so far north as Nova Scotia. It favours rich, rocky woods, and at its southernmost limits is found only in the mountains.

Eminently suitable for cultivation in the rock garden or border, it is an old and well-tried plant which should not be overlooked when new planting is contemplated. The heart-shaped leaves are sharply lobed and toothed, with a few hairs above and downy beneath. The simple racemes of white, feathery flowers are decidedly attractive, and are produced freely during early summer.

Tiarella cordifolia appears to prefer a rather moist, but not too wet situation, with a rich, well-drained root-run. *T. H. E.*

EARLY-FLOWERING SAXIFRAGA

THE numerous and varied species of Saxifraga include a number that flower early in the year, and as the blooms are often destroyed by stormy weather in early spring, they are best protected by fixing sheets of glass over them, allowing sufficient room for plenty of air, if the full beauty of the plants is to be enjoyed. The alpine house is the ideal place in which to grow these early-flowering subjects, where their charming flowers are not subjected to the inclement weather conditions that very often prevail during the early spring months. If an alpine house is not available, then a span-roofed frame where plenty of air may be admitted forms a suitable structure for the purpose.

The premier position for early-flowering must be given to S. Burseriana and its varieties, this native of the southern Alps and its numerous forms being among the best of the genus, and in the alpine house they will continue to give a succession of flowers from January until other varieties of the Kabschia group come into bloom. S. Burseriana is a variable plant and has many forms which are distinct in flower and foliage. Among the most distinctive will be found S. B. var. major, with broader, spiny leaves and larger flowers than the type; S. B. var. Gloria, a large-flowered form of robust habit; and S. B. var. tridentina, a charming variety from the Dolomites, its large, reflexed petals being slightly waved at the edges. The variety known as S. B. var. crenata is an attractive plant if the best form is grown, the edges of the pure white flowers being beautifully crenated.

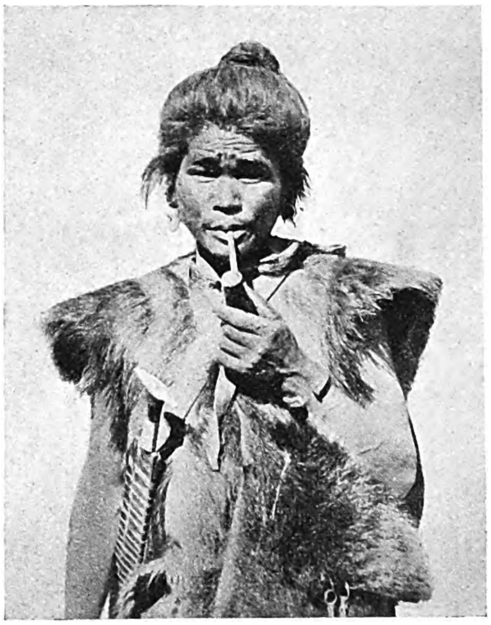

FIG. 118.—THE GAM OF TABLEKEN.

He tried to prevent Mr. F. Kingdon Ward's advance.

Among hybrids which flower early in the alpine house S. Kellereri is quite one of the best, with pretty rosettes of leaves which are pitted and mottled. The flowers are freely produced and borne on stems about six inches high, three and four flowers being carried in a head; the colour is a pale rosy-pink, and the blooms last a long time in good condition. S. kestonensis is stated to be a cross between S. Burseriana and S. marginata, but is a distinct sort, and is often covered with its pure white flowers by the middle of January. S. Sundermannii is a cross between S. marginata and S. Burseriana; it has beautiful, pure white flowers, and extremely attractive, glaucous, pointed leaves. The flowers, borne in heads of three or four, on stems about three inches high, are tinted with red in their young state.

S. Lady Beatrix Stanley is a charming hybrid of compact growth, with beautiful pink flowers; this variety received an Award of Merit from the R.H.S. on March 25, 1924, and is a cross between S. Godroniana and S. lilacina. S. Perle Rose is another of the same cross, and has flowers of a delightful soft pink; while S. Riverslea has much darker flowers, the interiors being of a dark purple-rose colouring. It forms neat little cushions of growths, which are attractive even when not in flower. S. Ada is stated to be a hybrid of S. tombeanensis and S. Burseriana var. crenata; it forms delightful, compact plants, the foliage being of a glaucous hue, while the flowers, which are produced very early, are of a pale rose colour. S. Sparkling is of very dwarf habit, having practically no stems, but like all others of this section, the compact form of growth is most attractive. The flowers are of a bright rose-pink shade. *F. W. G.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XVII.—ANOTHER ADVANCE.

BY the middle of April we had stripped our camp to the bone, and the next advance was fixed for the 19th, fifteen coolies being promised; we needed at least that number if we were to move ourselves in even moderate comfort. But we could never depend upon our transport; three coolies might turn up, or twenty, or none, and from day to day we were left guessing. When coolies did come in, we sent on ahead every load we could spare, or invent, ourselves remaining until the last. During these days we lived in a perpetual upheaval, due to the continual re-packing of boxes and re-shuffling of loads, an art at which Buttercup, as quarter-master, soon developed a vulpine cunning. Our one object was to get on up the valley while the Rhododendrons were in flower and before the rains broke. But to move even our skeleton camp, tents and all, required at least fifteen coolies, for we did not want to repeat the attrition tactics of our last camp, by which we had finally been reduced to travelling in two detachments, without tents or even proper food. That sort of thing is all very well now and again in an emergency, but it is not good to make a habit of it.

At no season is it easy to get coolies in the Mishmi hills; the population is infinitesimal compared with the size of the country, and scattered, and distances are great, or rather, routes are long and devious in the hill jungle. Moreover, scanty and diffuse as the population is, it is in reality concentrated in certain well defined areas—arable valleys to wit, up to a certain definite elevation—and the uninhabited areas of virgin forest are vastly greater. In the spring, when half the able-bodied population is still away, and the other half, together with the disabled, are engaged in the agricultural industry, it is almost impossible. Nor is the Mishmi a willing worker; unlike the more virile tribes of the frontier, such as the Lisu, who seem to thrive on a hard life, or the slave tribes such as the Nung, whose tradition it is to work, for strangers especially, the Mishmi hates work; only stark necessity makes him. At certain times of the year, when nature releases a number of men from the fields (periodical weedings being carried on by the women and children), the unemployed display no anxiety to find work. And in the search for coolies, the village *gams*, although the ultimate and indeed the only source of authority, were almost as casual and unreliable as the independent coolies themselves. Being in unadministered territory—and this is the reverse of the medal—we could bring no sort of pressure to bear, other than that of financial inducement, and coolies just came or not, as it suited them. Our only asset was the somewhat nebulous prestige of the white man, which, to jungle tribes, many of whom had never seen a white man before, did not amount to much. Add to this that our interpreter turned out a complete dud, and was either terrified of the Digaru Mishmis, or in league with them, and our difficulties will begin to be appreciated.

Yet we were not unduly apprehensive. After all, we were moving a good deal of dead-weight about with us, stores and rations for some months, an extra tent, winter clothes, and all the rest of it; once we had dumped this dunnage in some good base camp, and could move with a light camp, things, we assured ourselves, would be different. Alas for that Kruschen feeling! We did not yet know our little Mishmi friends! In short, to anticipate, we reached a certain point in the upper Delei valley (Fig. 120) according to plan, and then found ourselves almost completely immobilised. I should advise any future explorer, who is ambitious to make botanical discoveries in the Mishmi Hills, to provide himself first of all with a light aeroplane of unimpeachable perching powers; he might then reach some of the high peaks.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; and March 2, and 16, 1929.

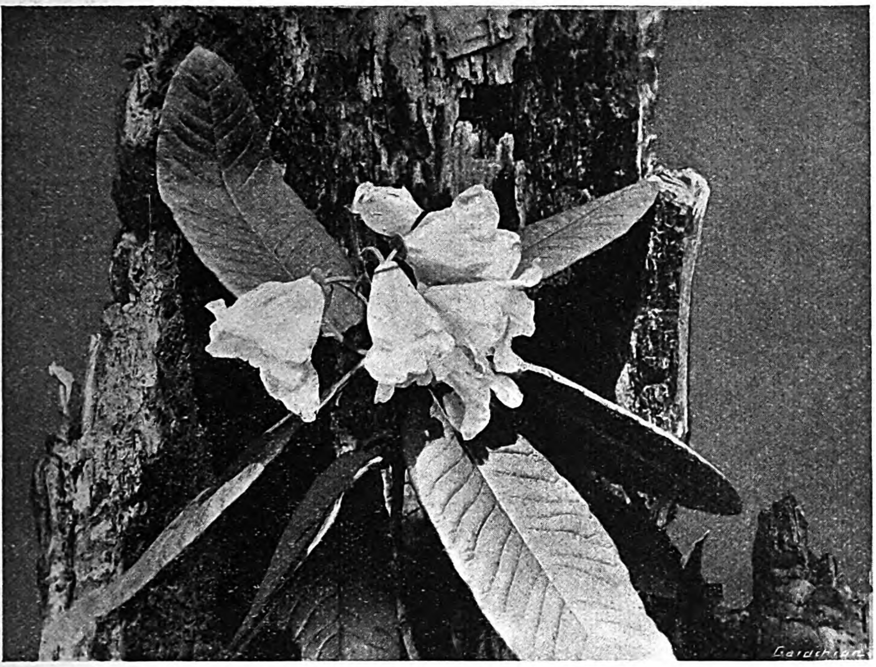

FIG. 119.—RHODODENDRON "BIG BILL THOMSONI."

However, despite our worst forebodings, we did get away from Chibaon on April 19. After passing through the next village, which turned out *en bloc* to see us, we reached a ridge overlooking a deep ravine, the bottom of which was 1,500 or 2,000 feet below us. We could see our destination, a village on the far side, about two miles away in an air line; but it took us the rest of the day to get there.

Buttercups and Forget-me-nots were the chief flowers we noticed along the path and at the top of the ridge, altitude about 5,000 feet, were thickets of mixed shrubs, including the handsome Holly already described and another species whose leaves were produced into flagellate drip tips, and stunted bushes of the 'Stamineum' Rhododendron, pollarded by the wind into neat standards. On the way up to the village across the ravine we found plenty of ripe yellow Raspberries (Rubus ellipticus). The day was fine, but cloudy, and by the time we were under canvas on the hillside it had begun to rain.

Just above our camp a bulge of rock, which ribbed the mountain range behind, curved down and outwards to drop almost perpendicularly into the river gorge. Behind this obstruction, which masked the view up valley from Chibaon, the river changed direction somewhat, curving from the north-east. Once round the corner, we quite expected to see a marked change in the vegetation, Pine-clad slopes instead of this everlasting rain forest; for the mountains to the west and south of us, which lay between us and the plains whence the rain drives inland were piling up both in bulk and in height, and ought by this time to form a pretty effective rain screen, we thought.

After a night's rain, April 20 dawned with the promise of fine weather, and we hastened up the slope to the brow of the ridge, reached just as the sun put the clouds to flight. The view which greeted us was indeed a fine one, but alas for our hopes, there was not so much as a hint of a change in the scenery or vegetation. The Delei river still snaked its way between overlapping buttresses in a gorge 2,000 to 3,000 feet below us. The path still skirted the precipitous flank of the mountain, winding round dark gullies, plunging into ravines, scaling cliffs. And everywhere dense forest clothed the face of the valley. Even the sight of snow-clad peaks towards the head of the valley was not much relief; for how could we reach them unless a change came over the scene! So far as we could see, conditions would continue like this indefinitely, and for the first time since we left Sadiya I began to have misgivings.

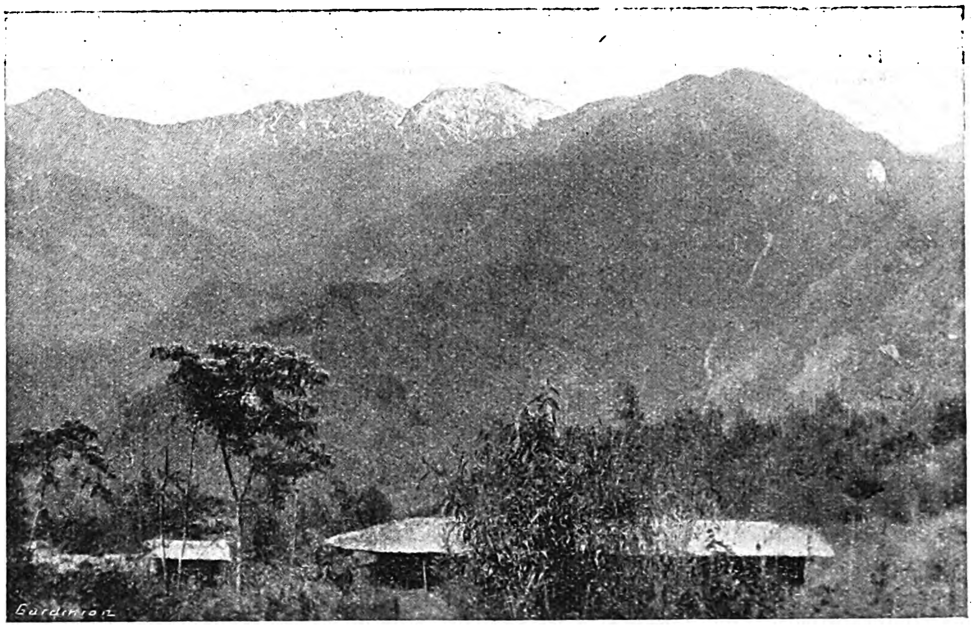

FIG. 120.—A MISHMI VILLAGE IN THE UPPER DELEI VALLEY.

The day's march was long and tiring, the path being execrable. Most of the time we were in forest, the bend of the river throwing the whole of the outer arc of the valley into shadow. Here I noticed a large number of Podocarpus trees, either immature or else males; Rhododendron arboreum, the 'Stamineum,' and on the final spur overlooking the next big stream, 'Big Bill Thomsoni' (Fig. 119) in magnificent bloom. The amethyst Orchid (Phaius) was common, and a small mauve-flowered Veronica. Descending a knife-edge ridge, there were Orchids under the trees and on them, only the former in bloom; among the latter a Pleione—possibly P. maculata—looked promising, also a big Dendrobium. There were a few plants of the slashing red Aeschynanthus here also. Finally, we came out into the open hillside and saw our camp on a terrace above the stream, more than a thousand feet below us. The slope was covered with grass and Bracken, and so steep that we had to go carefully; at the bottom we were hardly more than 4,000 feet above sea-level, but it was a nice camping ground.

One undeniable advantage of our third camp was that we were not dumped down in the middle of a village; such publicity, even in these days, was not to our liking, being of a kind which brought penalties with no compensating advantages. The nearest village, in fact, was some distance away, and the site of our camp, although open, was more or less private. True, the 'main road' up the valley ran through the estate, but pedestrians were few, and there was no dust. A little cultivation in the neighbourhood brought the agricultural labourer within hail each day, keeping up a liason between our camp and the village. To the east, a fairly high peak, still covered with snow, on the watershed between the Delei and Dou rivers, looked, and in fact was, quite close. The *gam* seemed friendly, if a little bewildered, in so far as anyone as dour as a Mishmi could seem friendly; he produced transport for the next stage more promptly than anyone hitherto, but perhaps that was only because he was anxious to get rid of us. However, we were too low down in the world here to be able to discover much about the alps, and were anxious to press on towards the head of the valley. Nevertheless, although we spent only five days here, we succeeded in ascending to 9,000 feet, eventually reaching a ridge which ran straight up to the main range, and finding several good Rhododendrons. On the other side of the Delei the mountains were lower; being terrifically steep, the walls of the gorge hiding the snowy peaks which lay further back. *F. Kingdon Ward.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

KURUME AZALEAS.

In the City of Kurume, southern Japan after over one hundred years of selection and hybridisation of Rhododendron obtusum by enthusiastic fanciers, there has arisen a remarkable race of Azaleas renowned for the wonderful colours of their flowers. About the year 1903 these were named the Kurume Azaleas, thus separating them from the type (R. obtusum) whose name in Japan is Kirishima Azalea. Some one-hundred-and-forty years ago Azaleas became very fashionable among the people of the Kurume clan, who went to the woods and mountains of the provinces of Higo and Satsuma, where R. obtusum is naturally abundant, to collect them, but they only wished, at that time, to obtain big and aged shrubs for their gardens or for use as dwarfed shrubs in pots. Some eight or nine varieties were then known. Mount Kirishima, in the latter province, is well-known for R. obtusum, therefore this exquisite Azalea is named after that mountain. The people of the Kurume clan were content with some eight or nine natural varieties, but were not interested in new varieties; but some thirty or so years later, while the Kurume Azalea was the fashion of the clan, people became somewhat tired of their hobby. Grieved at this and desiring to relieve the monotony, a clan retainer endeavoured to create new varieties. His name was Motozo Sakamoto, and he is regarded as the originator of what we now know as the Kurume race of Azaleas. He collected seeds in the temple grounds of Bairinji and Takarayama and elsewhere, but failed to germinate them for several years. Successive failures did not discourage him, but one day, so it is said, the wind blew away the seeds as he was about to sow them. This disheartened him, and he was giving up his ambition when he discovered that the seeds which had been blown away were germinating on the moss. That "inventions often owe their origin to accidents" is true, and Nature teaches us to follow her. Afterwards, he was successful and obtained as seedlings, many new varieties which excelled in colour and form. Many years passed, and he gave plants to Messrs. Yojiemon Nishio, Richu Kasai, Ichizo Yamada, En Takei, Kunie Miura and Kamejuro Imoo. Mr. Nishio, a magistrate of the Kurume clan, originated a variety called Narumi Kasane and it was one of the favourite varieties of Sakamoto. The celebrated varieties Sin Seikai, Suetsumuhana and Yasunishi Takamakie, were raised as seedlings in the garden of Mohachiro Yasunishi. His skill and cleverness greatly advanced methods of culture and the creation of new varieties. These specialists held an exhibition of new varieties each year and competed with each other in culture and variety mutually. The varieties they originated exceeded two hundred, but they agreed not to give any away, and so none was distributed until the Meiji Era. It may be of interest to English readers to know that in a list published by them, a variety named Igirisu (=England) is mentioned. Motozo Sakamoto died on May 18, 1854, at the age of seventy. Three old Azaleas, Azumakagami, Asahi, and Miyakobeni, which Sakamoto cultivated and trimmed, are still in the garden of Mr. K. Akashi, who regards them as treasures.

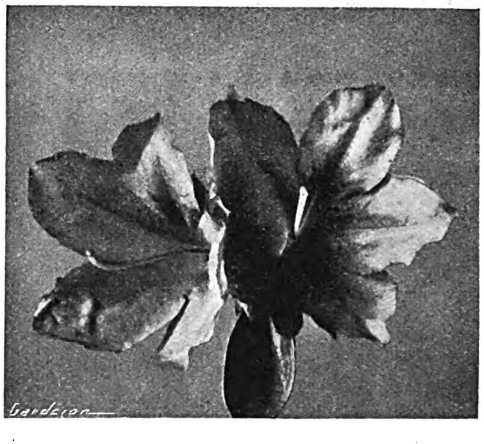

FIG. 121.—KURUME AZALEA NIKKO.

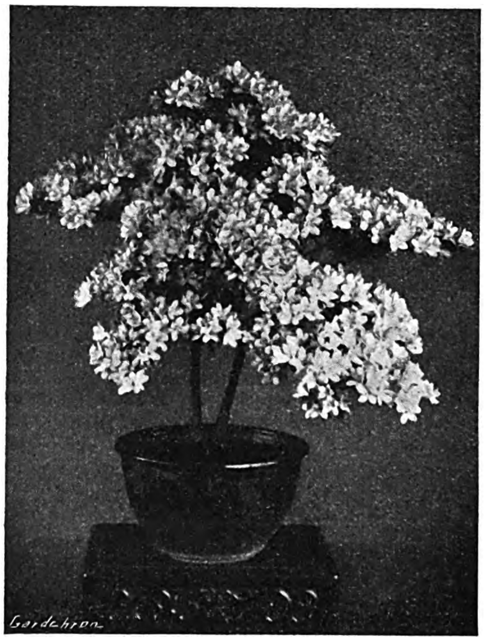

FIG. 122.—KURUME AZALEA YOSHINOYAMA.
A Plant thirty years old.

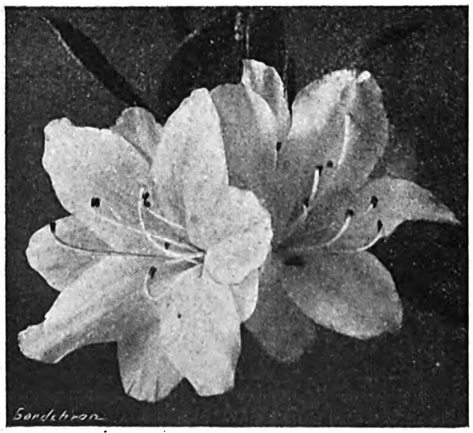

FIG. 123.—KURUME AZALEA KARIGOROMO.

The Kurume Azaleas became fashionable again in the year 1891, and so continue to this day. Many new named varieties are offered each year in the nurserymen's catalogues. Messrs. Akashi-Korakuen, Kurume city, are among the largest raisers and growers; during the past twenty years this firm has raised many meritorious varieties by crossing. In May, 1918, when the Azaleas were in full bloom, Mr. E. H. Wilson visited Messrs. Akashi-Korakuen and, later, he published a splendid work on Azaleas (*A Monograph of Azaleas*), Messrs. Kuwano-Yoseien, Kurume city, are also large growers of these plants, and the Yokohama Nursery Co., Tokyo, cultivates Kurume Azaleas extensively.

The flowers of the Kurume Azaleas are divided into eight types:—

1. Choko (a Japanese wine cup) type.—The petals are broad and open, with roundish apex. Model flower:—Kayoi-Komachi (Fig. 126, p. 247), reddish-pink, striped with reddish crimson, white throat, semi-double, large; Kokonoe, soft purple with white throat, semi-double; Shakukyo, bright crimson, single. The majority of the single-flowered Choko type are scarcely ornamental.

2. Swoad type.—Petals narrow, with pointed apex. Model flower:—Kamo (Fig. 127, p. 247), creamy-white, with purple apex, turning with age to pure white, with a purple apex; semi-double, raised in 1929; parentage, Irohayama × Benzaiten; Kamo is regarded as one of the finest of this group.

3. Common type.—Model flower: Shiga (Fig. 128, p. 247), purple, eye white, striped with dark purple; single; very large and one of the best; parentage, Irohayama × Daikun; raised in 1927. Mikaerizakura, pink, with white throat, single, is very popular; Takasago, pink, semi-double, is the best pink sort.

4. Minokake type.—The outer petals are smaller and curled. Model flower:—Mikushi-shibori, white, striped with reddish-crimson.

5. Ipponjin type.—The stames are imperfect and adhere to the throat, while the pistil is perfect. Model flower:—Nikko (Fig. 121), bright crimson with white pistil, single, fine; Fukashigi, reddish-crimson with white throat, single. Although the flowers of this type are not so fine and large as in other groups, they are much appreciated by Japanese fanciers.

6. Double-flowering type.—Mixed semi-double and double flowers on one plant. Model flower:—Hakuo-Nishiki, creamy-white, striped with reddish-crimson; very large.

About three hundred varieties are offered. The model flowers above mentioned are all the best and most popular varieties, but the following are also popular:—Irohayama, light purple, single; Kurai-no-Himo, salmon, large, semi-double; Suetsumuhana, bright crimson, the best of single crimson sorts; Tokonatsu, white, striped with reddish-purple, large single; Kure-no-Yuki, the best semi-double white; Kirin, reddish-crimson with dark crimson throat, semi-double; Imashojo, the best of semi-double, bright crimson sorts; Azumakagami, pink, very large, semi-double; Ouchi-Yama, dark lilac-purple, semi-double, the best of its colour; Susogo-no-Ito, dark purple, single, the best purple; Wakaba, red, slightly tinted with cinnabar, single, one of the largest flowers; Karigoromo (Fig. 123) is one of the best of recent introductions, being snowy-white, striped with bright crimson; very large (Yoshinoyama × Daikuni).

Many of the best varieties of recent years have been raised by Messrs. Akashi-Korakuen, and the popularity of the Kurume Azalea is, indeed, largely due to their work, and their nurseries (Figs. 124 and 125) are worth going a long distance to see.

They have originated another fine race of

Azaleas named the Kurumesatsuki Azalea, the result of crossing the Kurume Azalea with varieties of Azalea indica (the Satsuki Azalea). Although only ten years have passed since Messrs. Akashi-Korakuen commenced the work of creating this new race, they already have about fifty varieties, of which the following are some of the best:—Nissho, reddish-crimson, white throat, single Swoad type; Matsukaze (Fig. 129), purplish-crimson, with white throat, single; Kiju, clear peach-colour, slightly tinted with purple, white throat, very large, single; Gekkeikan, pure white, striped with pinkish-purple, single; and Hinomaru, bright crimson, large, single. The flower buds of this race are not affected by late frosts as are those of Azalea indica, one of the parents. The Kurumesatsuki Azalea flowers in May, commencing at the beginning of the month.

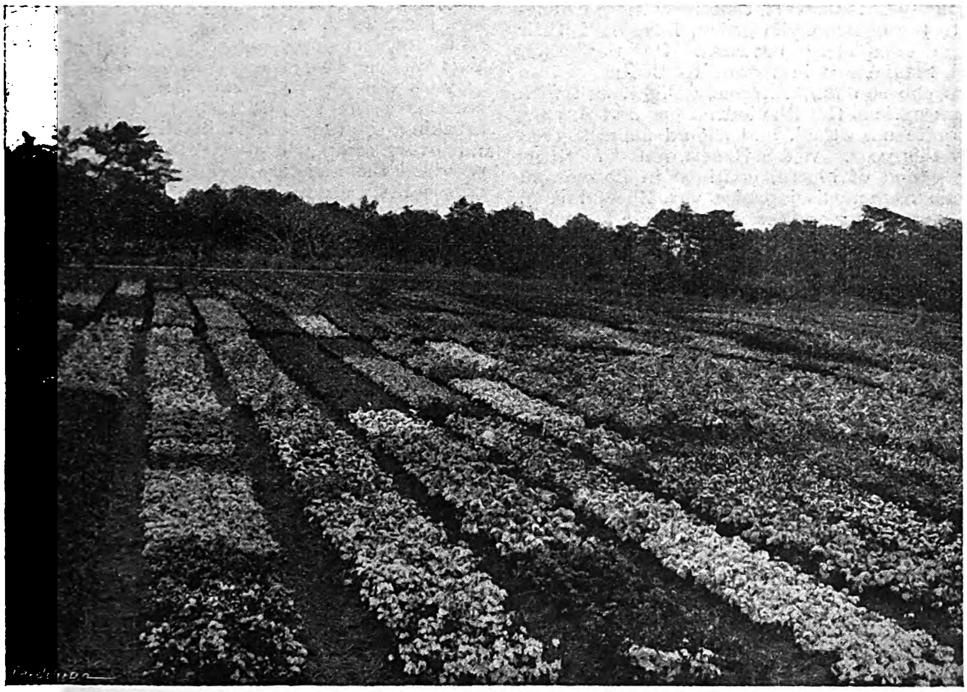

FIG. 124.—KURUME AZALEA NURSERY OF MESSRS. AKASHI-KORAKUEN AT OGRI, JAPAN.

Porous, well-drained, loamy soil is most suited to Kurume Azaleas, and the compost used is a mixture of five parts loam, one part leaf-mould and four parts sand. Planting takes place from October to May, but the best time is just after the plants have finished flowering, while November to March is a good time for exporting. During the growing season Azaleas need a fair amount of water and syringing in the evenings, and they should be shaded from strong sun to maintain the flowers and the foliage in good health. The late frosts often affect the petals. Immediately after they are potted Bean-cake is scattered among them; once a month an application of Bean-cake is given until November; manuring in spring often damages the flowers. After the flowering is over, the plants are cut back, thinned and trimmed so as to secure plants of good shape; in response to this care, they produce a mass of wonderful brilliant colour each year. The specimen (Yoshinoyama variety) in the pan (Fig. 122) is thirty years old, and shows the dwarfness and floriferousness of the Kurume Azalea. The umbrella-trimmed specimens (Fig. 125) are most popular, and these are only formed and maintained by long years of skilful management.

The Kurume Azaleas are useful alike for planting in the shrubbery border or for edging borders, as they are dwarf and bushy in habit. They are also useful for carpeting among other kinds of flowers, giving bright colour in spring, pleasing green summer foliage, and rich autumn tints. These Azaleas force well in the greenhouse.

Cuttings should be struck (after immersion in water from one to four hours) in June or July, when the new shoots are somewhat hardened and it is the rainy season in Japan; they are placed in the outdoor propagating bed, and are made from two to three inches long; in one year they become four to twelve inches long. They must be watered carefully and shaded until they form roots. If propagated under glass, the cuttings are usually inserted in pure sand, and form roots in two weeks or so; some growers use Sphagnum-moss. If a box or pan is used it should be half-filled with crocks and charcoal, which should be covered with pure sand. After inserting the cuttings, they should be watered in well and syringed twice or thrice a day.

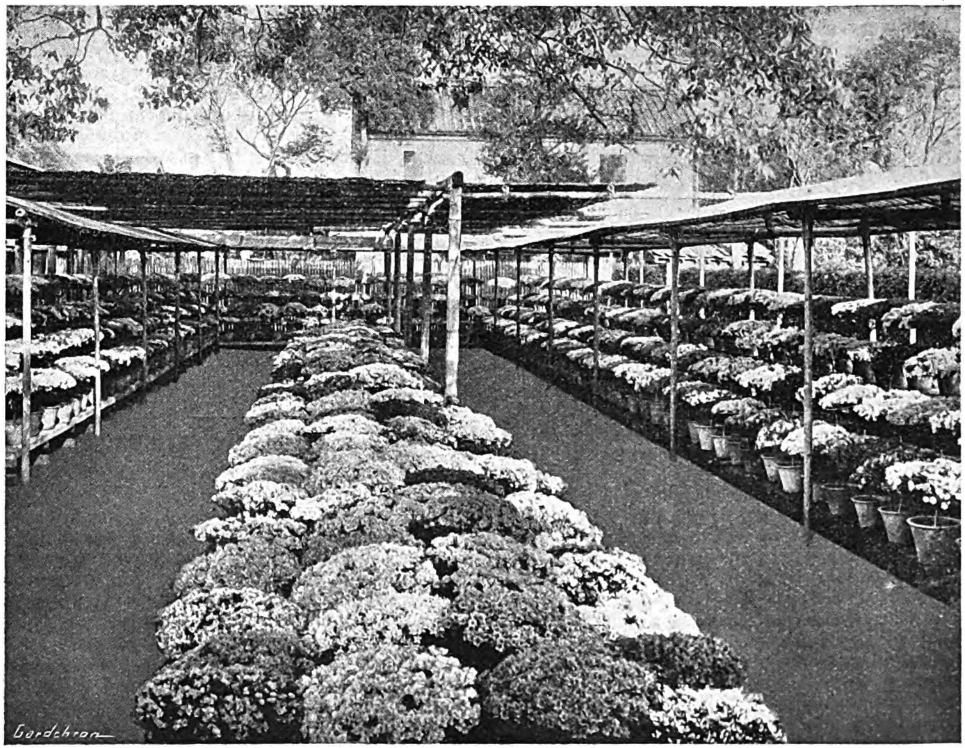

FIG. 125.—KURUME AZALEAS IN KURUME CITY, JAPAN.

Grafting is employed for the purpose of quickly multiplying new varieties. Yodogawa, the most vigorous and rapid-growing variety, is used as the stock. In the sowing of the seeds and the treatment of seedlings the methods practised are as for Rhododendrons and other Azaleas.

I consider the Kurume Azalea is one of the finest of Japanese introductions, and I admire the splendid work of originating and improving this beautiful race of plants. *K. Yashiroda, Tonosho-Kyoku, Kagawaken, Japan.*

NOTES FROM A WELSH GARDEN.

Although it is too soon to estimate the full loss sustained by the recent frosts, it is only too painfully obvious that the day of reckoning will be a melancholy one. When there are 22° of frost registered on a sheltered wall there is very little hope for anything in the open not absolutely hardy, and even here we had weather of somewhere about that severity for at least a fortnight. Fortunately for the smaller things, this frost was preceded by a fall of dry, powdery snow which gave them some protection.

Most of the New Zealand shrubs were killed outright, old specimens of Leptospermum having their bark split on branch as well as stem. Very few Veronicas and Cistuses are left, all shrubby Senecios and most Olearias are beyond repair, and even such reliable things as Helianthemums will practically all have to be replaced. It is doubtful if Eucryphia cordifolia and Tricuspidaria lanceolata will recover, and I am no more hopeful of Berberidopsis corallina, a long-established plant on a sheltered wall. A few curious incidents may be noted. Erica arborea was destroyed, but E. australis close by was only partly injured. Convolvulus Cneorum, quite in the open, is unharmed, yet Daboecia polifolia is all cut to the ground level. Mutisia decurrens is apparently untouched, notwithstanding its fresh, sappy tips. Yet there are patches of Calluna vulgaris so brown that they look as if they had been scorched by fire. Ceanothus rigidus, usually regarded as tender, is unharmed, but C. Veitchii and C. papillosus are beyond hope. But why continue the sorry tale? Most of us are in the same boat, and a cargo of adversity is a cheerless freight.

Moreover, there are some compensations to record. The covering of snow and subsequent period of rainless weather and unbroken sunshine have been ideal for the early Saxifrages. S. Griesbachii, S. Bursiculata, the dainty S. kewensis, S. Boydii and the rest of their charming class, are exceedingly happy. Had these been in an alpine house they could hardly have looked brighter and better. Some of the early Drabas are also enjoying conditions which are associated with the southern Alps at this season, and the pale yellow of these, with the first of the miniature Narcissi (notably N. minor var. minimus) unite with the intense blue of the Muscaris, Chionodoxas and other early bulbs in a pleasant reminder that spring is already well on the way in the rock garden.

The Snowdrops in the woodland, which, by the way, are spreading abundantly by means of seeds, in a ground-covering of Ivy about eight inches thick, were joined by the first of the Daffodils before the middle of March, despite the continuance of frosty nights. Then followed the Erythroniums of the Dens-canis section, and I know of nothing more delightful than these beneath the leafless trees. Every season more are planted yet one never has enough of their elfin grace and soft colouring, and before the last are over others of the genus will have come to carry on their season until well into May. Corydalis cava is also a faithful woodlander with a pleasing fragrance, rare in its race, the white form being especially attractive among the Ferns of its shady retreat. A selected form of Pulmonaria azurea, exceeding Mawson's both in the size and blueness of its flowers, makes a welcome patch of colour upon the frost-bitten herbage of the woodland. P. arvernensis var. Mrs. Moon stands out distinctly from others of the spotted kinds, both in earliness and the much larger blooms which are a pale shrimpy-pink when full. But in Pulmonarias other than blue there is none, I think, to approach P. rubra, which I alluded to last month (p. 142). It is odd that Farrer (*The English Rock Garden*) should have regarded this species as a form of P. arvernensis, and one can only surmise that he did not possess the true plant.

Rhododendron praecox, retarded until now; has opened some of its lovely blossoms, but even in their very sheltered position the chances of their escaping frost are rather remote. On the other hand, that delightful little shrub, Erica carnea var. Vivellii, is a mass of rich cherry-rose. It is a little paler in tint, perhaps, than usual, as are all winter-flowering Heaths, probably owing to the absence of rain, but its fine colour and extreme hardiness are particularly gratifying just now.

One is glad of the Primroses when even Aubrietias look like bunches of hay, and both the singles and doubles are already making quite a good show. Among these the big yellow blooms of Evelyn Arkwright will not be passed unobserved, while in the numerous P. Juliae clan I do not think there is one so appealing in its diminutive neatness and depth of colour as Pam. P. Winteri will be in flower before these notes are in print. Lovely as that species undoubtedly is, one cannot allow these choice and fastidious things entirely to queer the pitch of such reliable old friends as P. denticulata. The almost spherical flower-heads of the latter are a delightful colour, they are no trouble to produce, for the plant will prosper under almost any conditions, and in a season such as this the weather-proof qualities of P. denticulata, its uncomplaining adaptability and cheerful blooms, remind us of our indebtedness to such familiar, well-tried plants as this. But to get the best out of P. denticulata it must be given rather lean treatment or its charm will be lost in coarseness of leaf and flower.

The warm sun of the last few weeks, and a day temperature which has touched 69° on several occasions, has been just the thing for Iris unguicularis. Notwithstanding the fact that its foliage was browned by the frost, this lovely Algerian species is flowering gaily in a mixed border. Like many other plants, the fragrance of this Iris varies with the season, or the conditions, but it never seems so deliciously scented as it is under more southern suns. *A. T. Johnson, Ro Wen, Conway, North Wales.*

NOTES FROM WISLEY.

As a result of the great frost, numbers of plants in the gardens at Wisley are looking very sorry for themselves. Shrubs, such as the Ceanothuses, have naturally been severely cut, and many Cotoneasters, especially those belonging to the glaucophylla group, have had their foliage completely browned. On the other hand, the damage in regard to Cistuses is, so far as one can tell, extremely slight, and with few exceptions the Rhododendrons and Azaleas are quite unscathed, and should make a good show this year. Witch Hazels, noted for their long period of bloom, continue in flower and include Hamamelis japonica var. Zuccariniana, H. j. var. arborea and the earliest of all, H. mollis. Other deciduous shrubs are now showing bloom as, for example, the common Hazel, Cornus Mas, with its yellow blossoms, and Parrotia persica, whose brown, cupped flowers betray a gleam of scarlet.

Flowers are also to be seen in the borders around the laboratory, where some monster varieties of cultivated Snowdrops are in bloom. Most of these are very clumsy in comparison with the wild type. More pleasing are the flowers of Iris unguicularis, of which there is a very dark-flowered variety known as angustifolia. Its colouring approximates to that of Iris reticulata, which is in bloom in the same border.

The alpine house, during sunny periods, attracts numbers of hive bees which work among the flowers of Saxifraga Burseriana and its many varieties, of which those that have recently commenced to bloom are S. Burseriana var. Gloria, with very large flowers, and S. B. var. sulphurea, with pale yellow blossoms. Other Saxifrages in bloom include S. Riverslea, a fine S. Engleri hybrid with pinkish flowers borne on crimson, hairy pedicels, and S. lilacina, which is now a mass of pale mauve blossoms.

A pretty little Iris in bloom in the alpine house is I. Cantab, with pale, smoky-blue flowers which give forth a pleasant fragrance.

Now that the severe frost is past, the Crocus species in frames are beginning to flower abundantly, and when the sun is out are extremely attractive. Some of those with broad perianth segments resemble miniature Water Lilies when fully expanded, none more so than the very handsome white form of C. Imperati.

The rock garden plant life is beginning to move at last, and on the banks of one of the top rock pools is a little colony of Adonis Nadorkaki: the bright yellow flowers with their feathered margins are particularly striking. Plants of Primula Winteri, the flowering of which was interrupted by the cold spell, are now resuming their duties and seem likely to provide a show of bloom which will last well into the spring. *J. E. Grant White.*

BOG AND WATER GARDEN.

PRIMULA ROSEA.

If one were making out a list of the best half-dozen Primulas for the average garden, it would be hard to exclude P. rosea. Many of us are getting rather tired of the troubles inflicted upon us by a number of the newer kinds, and even some of the older ones which ought to do almost anywhere and prove perennial, are apt to need constant renewal. It is therefore with unqualified admiration, begotten of long and unfailing satisfaction, that one is still able to regard P. rosea as a species of the foremost rank. Botanists tell us that it ought to be called something else, since its name covers a number of Himalayan Primulas. But I rather think that the plant most of us know as P. rosea will always be recognised in gardens by that name. Although a lover of wet places, delighting in boggy soil, and even growing in shallow water, P. rosea is so adaptable that it will prosper in any moist border or even a cool corner of the rock garden. It makes a clump of rather small, glossy, pale-green leaves which die back entirely in early autumn. In spring, long before most bog-plants are beginning to move, the plants become studded with vivid carmine buds. These expand as the flowering stalks rise, and by the time the latter have attained their full height of three or four inches, each is bearing an ample head of large blossoms in a lovely shade of carmine-rose with a yellow eye. This typical form is delightful enough, but there is a taller one, listed as P. r. var. grandiflora, which has still larger blossoms and an eight-inch stalk. This is always worth a place, and it is quite as easy as the type. P. rosea is such a willing, amiable plant that it may be increased by breaking up the clumps in the late summer and every scrap will grow. It enjoys full sun, provided the moisture supply is ample, otherwise a little shade is desirable.

CARDAMINES.

If the double-flowered Lady's Smock (Cardamine pratensis) is by a long way the best of its tribe, I must confess to a liking for the lush-leaved C. macrophylla. In the right place, among other robust growers about the margins of pool or stream, the fresh green foliage and bright purple flower heads of this plant are very attractive. It is, moreover, early flowering, giving colour in masses long before most waterside subjects have made any headway. As for C. pratensis fl. pl., its fine Stock-like trusses of bloom in a fresh lilac are well enough known and appreciated. This plant, however, can be a cause of much trouble in moist soil. In the rock garden or borders it is all that is delightful, but if it has an opportunity of establishing itself in or near the bog it may easily become a pest. Farrer refers to it as being "generous with self-sown seedlings which come true to their parent." Here he was surely in error, for while I have never seen a seed on this double Cardamine, there is evidence in plenty of its ability to increase itself by vegetative means, many a wind-blown scrap of leaf or stalk striking root in moist soil. However, I am inclined to think that collected native double-flowered forms are much more prolific in that method of reproduction than the plant commonly seen in rock gardens. I was once indiscreet enough to bring home a tier-on-tier form found in a moorland ditch, and have abandoned all hope of ever seeing the end of its multitudinous leaf-born offspring. There is, or was, a pure white variety of the double Lady's Smock, a useful plant, but unheard of now.

C. trifolia is a pretty woodland species from Switzerland and south Europe. In a cool, good soil it will make a dense mat of dull green, leathery, Trefoil leaves. Above these, on three-inch stems, the snow-white flowers appear in early spring. But C. trifolia misses being a front rank plant.

RODGERSIA TABULARIS.

If I were ever to be restricted to the growing of one Rodgersia, the subject of this note would be my choice. This, not only because it is the most distinctive of the various kinds in cultivation, but because, while it has larger leaves than any other, it is a plant that will do with comparatively little space. Most of the Rodgersias are too vigorous for the average amateur's garden, but R. tabularis will take a good many years in covering a square yard, and then it will confine itself to a self-contained clump. That, at any rate, is how I have found it after having had it in good moist soil near water for a sufficient time to enable it to be compared with others.

R. tabularis commences growth in spring, early enough very often to suffer from frost. But if the uprising leaves do get nipped they will be replaced later by a fresh crop. These leaves are peltate, round as a plate, and held erect on stalks about two feet long. They are about eighteen inches across, their drooping margins are slightly scalloped and their pale, downy green has that softness of tint which harmonises so sympathetically with their limp and delicate texture. The erect flowering stems rise to a height of three or four feet, so that they stand well above the leafage. These bear in summer waving plumes of milky-white blossoms. A second crop of bloom in autumn is not an infrequent occurrence. *J.*

HARDY FLOWER BORDER.

KNIPHOFIAS.

The genus Kniphofia is an extensive one comprising some fifty species, mostly natives of South Africa, and few races of plants produce such a striking and brilliant effect in the late summer and autumn as these handsome border perennials, commonly known as Red-hot Pokers, Torch Lilies or Flame Flowers. They grow well in a deep, loamy soil, which is well-drained, and although lovers of moisture, anything approaching stagnation is inimical to their well-being, and a frequent cause of losses in winter. Once established in a good soil, they require little further attention beyond an occasional top-dressing of decayed manure, and, besides being useful in the border, they are of great value for grouping at the front of shrubberies or in the open woodland, while, when planted in large masses near water, they are highly effective, particularly from a distance. Like many other fleshy-rooted subjects, they resent disturbance, and when replanting becomes necessary it should be done in the spring just before new growth takes place, when the plants may be increased by division. Seeds are produced freely in favourable seasons and afford a further means of propagation.

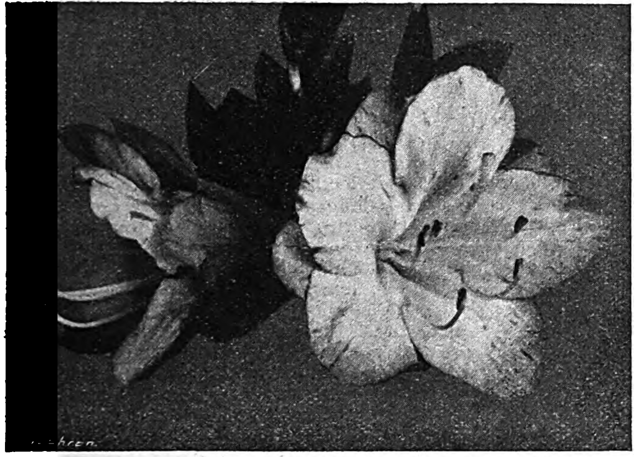

FIG. 126.—KURUME AZALEA KAYOI-KOMACHI.
(see p. 244).

In addition to the numerous species, there are large numbers of hybrids which have been raised in recent years, many of them being plants of exceptional merit, producing magnificent, long flower spikes of wonderful brilliance. K. Uvaria is probably the oldest species in cultivation; it is an excellent border plant, and has given rise to many handsome forms, one of the finest of which is the variety nobilis, a handsome plant, sometimes raising its thick stems to a height of six or seven feet, surmounted by long heads of flowers which vary in colour from flaming scarlet to rich orange-red. K. caulescens is another old and well-known species with broad, glaucous leaves, and large, dense spikes of scarlet and yellow flowers. K. Macowanii is a distinct species with grassy foliage. It is one of the best of the dwarfer kinds, bearing erect spikes of richly-tinted, orange-scarlet flowers with remarkable freedom. K. corallina, stated to be a hybrid between K. Uvaria and K. Macowanii, is also a good dwarf kind, with brilliant scarlet flowers shading to orange. K. Tuckii is of comparatively recent introduction, and is earlier-flowering than many others, its spikes appearing so early as June, the flowers being red at first, changing to sulphur-yellow later. The plant is of distinctly tufted habit, and the leaves are somewhat stiff and tapering.

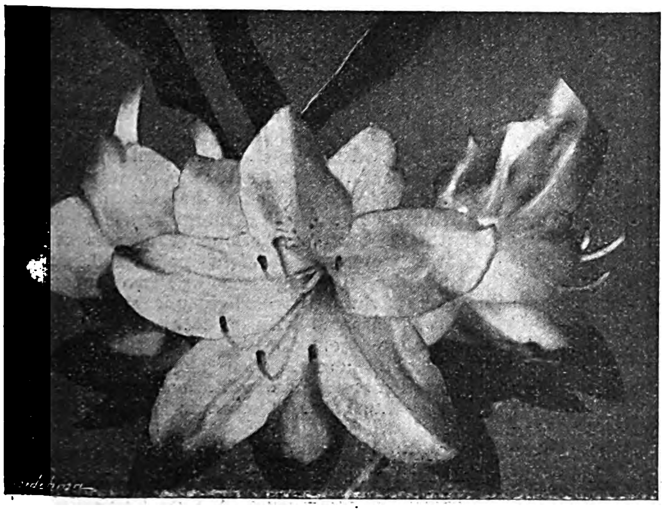

FIG. 127.—KURUME AZALEA KAMO.
(see p. 244).

Among hybrid Kniphofias of merit may be mentioned Jno. Benary, with large spikes of rich orange-scarlet flowers; Meteor, a tall-growing plant with coral-red flowers shading to orange; Triumph, with deep bronzy-yellow spikes, and Etna, with magnificent long spikes of rich scarlet, shading to orange. *W.A.*

MODERN HYBRID ASTILBES.

There was a time—remembered by most of us—when Astilbes were almost unknown as garden plants. We grew a few white-flowered species by the waterside, and then there were those old, rosy-pink hybrids Peach Blossom and Queen Alexandra, often called Spiraea japonica and familiar as decorative subjects in pots. But one day there came from China a splendid stranger, Astilbe Davidii, with towering bloom spires in a gorgeous, almost barbaric, blend of violet and crimson. The introduction of this sumptuous Oriental marked an epoch in the outdoor culture of Astilbes, for it is mainly to A. Davidii that we are indebted for those superb varieties which are so striking a feature of our best modern gardens to-day.

By crossing A. Davidii with the old A. japonica and others, a race of hybrids was produced which, while its members surpassed their parents in stature and elegance, gave a wide variety of tasteful colours. Subsequent selection and re-crossing being continued, a still further advance was made, with the result that we now have a range of Astilbes such as was undreamed of twenty years ago. Varying in height from two feet to six or even seven feet, these magnificent plants bear foamy inflorescences which are exquisitely feathered, light as air, and often half as long as the height of the entire growths. As for the colours of these delicate plumes, which are, by the way, singularly immune to the effects of rough weather, they vary from white to cream and ivory, from pale pink to deep rose, and there are some delightful salmon and flesh tints as well, with others in rich tones of violet, purple, crimson and amaranth.

Whether these hybrid Astilbes are grouped by the waterside or in the herbaceous border they will, under generous treatment, produce such copious sheaves of blossom that they easily hold their own in the most aristocratic company. And this they will do from July to late September when so many flowering plants are on the wane. In the majority of them the tints are so refined and delicate, and in all of them the flowers and foliage so extremely light and graceful, that some consider these plants should always be grown in groups of their own kind. But this is very much a matter of taste and expediency. They are seldom out of place, and it will be welcome news to some readers perhaps to learn that such admirable plants as these have proved exceptionally good subjects for town gardens.

The hybrid Astilbes enjoy the advantage of being very easily grown. They are practically all hardy, pest-proof and robust. All they ask is a fairly damp, rich soil with, if possible, a little shade from the hottest sun. But by the water they may always have full exposure. Being thirsty creatures they need plenty of moisture, especially during the earlier summer and when coming into flower, and the winter top-dressing of half-decayed manure or rotted vegetable matter can hardly be too liberal. Planting may be done in autumn or early spring, and propagation is a simple matter, for old clumps may be divided at any time during the dormant season, and every rooted scrap will grow. The only places in which Astilbes are likely to fail are dry, sandy soils and those in which chalk prevails.

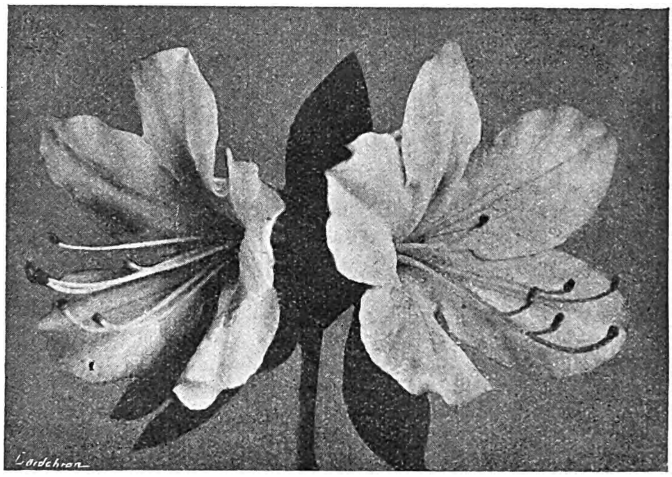

FIG. 128.—KURUME AZALEA SHIGA.
(see p. 244).

There are now so many of these Astilbes from which one may make a choice, and such a high level of excellence exists among them, that it is difficult to suggest a small selection. But among the taller growers I recommend Professor V. D. Wielen, a superb variety with wine-red stems and enormous pyramidal inflorescences of snow-white; King Albert, with very large, creamy-white plumes, and the deep red Salland. In those of about half the above stature, the rich crimson, Granat; the amaranth-crimson, Amethyst, and Gloria in an intensely vivid ruby-rose, are, perhaps, the best of their respective colours. Then, in the more tender shades, the grower's choice might be decided by Pink Pearl, one of the oldest but still to the fore; Salmin Queen, which is a lovely, warm rose; Siegfried, a pale silver-pink; the soft flesh-pink Ceres, and Astarte, a very dainty lilac. These, with White Gloria, as a pure white of about medium size, would make a very representative collection of these singularly charming plants. But any good nursery list will tempt the reader with dozens of other, and none of them are expensive. *A. T. Johnson.*

MIMULUS BARTONIANUS.

Fully expecting to find this plant injured, if not destroyed, by the recent frosts, I was surprised to see several of the oldest clumps already breaking into growth before the middle of March. These have had no protection whatsoever, and they are growing in a cold soil with clay near the surface.

This Mimulus is a hybrid between M. cardinalis and M. Lewisii and, writing from memory, I believe it was raised in Scotland a few years ago. It is not only hardier than either of its parents, but a more vigorous grower, a well-established plant making a bold mass three or four feet across and two feet tall. The grey-green leaves are viscous and the large flowers, which are a rosy-red with a yellow throat, are yielded in amazing prolificacy from the later spring to autumn. M. Bartonianus is, indeed, the first to flower here, and the last to go over. It is more slug-proof than most of its kind, especially when doing well, and the only attention my plants get is an annual top-dressing of decayed vegetable refuse applied in early spring. Propagation can be carried out by cuttings, but division is less trouble, and old clumps are none the worse for breaking up. A variety known as Sunset, which was raised recently by Messrs. Smith, of Daisy Hill, is a decided acquisition, the colour of the flowers being orange-scarlet. This very striking plant has so far proved to be as hardy as its parent. *J.*

THE GENUS PRIMULA.

(Continued from p. 230.)

MAGELLANICA (Lehm.). Magellan P.
(Farinosae.)

THIS plant is considered by most botanists to be a sub-species of P. farinosa. It is a robust, strong-growing plant with a large rosette of diamond-shaped-elliptic leaves, one inch to four inches long; margins coarsely toothed; upper surface usually smooth, underside mealy. Flower stem six inches to twenty-four inches tall, stout, bearing an umbel or rounded head of shortly-stalked, rose-lavender or white blossoms. Corolla similar to that of P. farinosa.

Grows in damp, exposed places, usually in elevated situations in southern Chile, Terra de Fuego, and the Falkland Islands.

Culture: As for P. farinosa; it is an easily grown plant.

MALACOIDES (Franch.). Fairy P.
(Malacoides.)

The type of this popular species produces a tuft of thin leaves with broadly oval blades two-and-a-half to three-and-a-half inches long and one-and-a-half inch to two-and-a-half inches wide, borne on rather slender stalks four to seven inches long; margins divided into from six to eight broad lobes furnished with pointed teeth; upper surface more or less smooth, underside covered with white hairs which secrete a little white meal at times. Flower stem six to twelve inches tall, bearing two to six superposed, many-flowered umbels of rose-coloured, or rarely white blossoms on slender stalks. Corolla slightly concave, half-an-inch across, divided into five broadly heart-shaped lobes; tube slender, cylindric, slightly longer than the calyx. There are two forms of this species in cultivation, one with small leaves and slender, graceful inflorescences, and the other a much coarser plant; there is also a double form. Introduced in 1908. (*Gard. Chron.*, 1923, Vol. LXXIII, Fig. 92, p. 203).

Grows in shady places in mountainous situations near Tali, in Yunnan, western China.

Culture: This plant is not particular as to soil, but to be retained as a perennial, the soil must be well-drained in winter; it will withstand as much as 14° of frost under suitable conditions.

MALLOPHYLLA (Balf. f.). Large Mallow-leaved P.
(Candelabra.)

A rather handsome, smooth, non-mealy, deciduous perennial species with a tuft of rather thin leaves five to seven inches long, with oblong or oblong-egg-shaped blades, rounded at the tip and tapering below into a short, winged stalk, dilated at the base, with the midrib of a bright red colour; margins sharply toothed as though gnawed by insects. Flower stem about twelve inches tall, robust, slightly downy upwards, bearing two to three superposed umbels of ten to twenty lilac blooms. Corolla about three-quarters-of-an-inch across, divided into five retuse, notched, egg-shaped lobes, with torn margins and a tooth in the sinus; tube membranous, about five-eighths-of-an-inch long, with a ring in the mouth.

This species is found in the district of Tchenkeowtin, in eastern Szechuan, central China.

Culture: As for P. japonica.

MALVACEA (Franch.). Mallow-leaved P.
(Malvacea.)

A handsome species with richly tinted blossoms. The leaves are produced in a loose tuft and have rounded, broadly oval blades two to three inches long, heart-shaped at the base, borne on downy stalks three to four inches long; margins furnished with coarse, blunt teeth or small lobes; both surfaces covered with short, fine down. Flower stem three to ten inches tall, stout, downy, bearing two to four superposed umbels of two to six rosy-red blossoms on stalks about half-an-inch long. Corolla about three-quarters-of-an-inch across; lobes broadly oval, bilobed; tube as long as the calyx, cylindrical, with a distinct ring in the mouth. Flowers in July and August. Introduced in 1908. (Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913).

Grows in open mountain pastures, usually on limestone formations, in north-western Yunnan at 10,000 to 11,000 feet above sea level.

Var. alba (Forrest), has white blossoms with a yellowish eye; it inhabits open alpine pastures in western Yunnan.

Culture: Good fibrous loam, leaf-soil and limestone chips in a cool, half-shady spot, should suit it.

MARGINATA (Curtis). Margined P.
(Auricula-Brevibracteata.)

A beautiful perennial species with a woody rootstock frequently reaching a foot in length, clothed with the dried remains of the previous seasons' foliage and usually more or less mealy. The smooth, greyish-green, leathery leaves, in tufts, have oblong or egg-shaped, blunt blades, margined with a conspicuous narrow edging of whitish meal and deeply and regularly toothed; they taper to a short stalk and measure in all one inch to four inches in length. Flower stem rather stout, one-and-a-half inch to five inches long, mealy, bearing an umbel of two to twenty lilac or bluish-lilac blossoms on stalks three-quarters- to one-and-a-quarter-inch long, coated with meal. Corolla broadly funnel-shaped, rarely flat, three-quarters to one-and-a-quarter-inch across; lobes rounded, cleft; tube cylindrical below, dilated upwards, many times longer than the calyx. Flowers in July and August. Introduced in 1777. (*Bot. Mag.*, t. 191).

Grows in crevices in limestone or granite rocks in sun and shade in the Graian, Cottian and Maritime Alps.

Culture: It may be grown in a level part of the rock garden in loam and limestone chips, but is best in a cleft of a limestone rock, in a cool, shady spot.

MAXIMOWICZII (Regel). Maximowicz's P.
(Nivales.)

A handsome, robust perennial species with a tuft of smooth, non-mealy, distinctly stalked or almost stalkless leaves from two to three inches long, with narrowly-elliptic or elliptic-oblong blades, pointed at the tip, margined with numerous fine teeth, or nearly entire. Flower stem seven to fourteen inches tall, smooth, non-mealy, stout, bearing from one to three superposed, drooping umbels of clear, dark purple blossoms on thread-like stalks three-eighths- to three-quarters-of-an-inch in length. Corolla about five-eighths-of-an-inch across, divided into five narrow, oblong, reflexed, entire lobes; tube cylindrical, twice as long as the calyx. Introduced in 1911. (*Gard. Chron.*, 1910, Vol. XLVII, Fig. 96, p. 221; *Bot. Mag.*, t. 8363).

Grows in damp mountainous situations in Shensi and Kansu, in northern central China, up to 9,000 feet above sea-level.

Var. brevifolia (Pax.), has nearly stalkless, almost entire, oval or oval-oblong leaves; flower stem four to seven inches tall. Shensi and Kansu.

Var. Dielsiana (Pax.), has distinctly stalked leaves, with toothed margins; flower stem seven to fourteen inches tall. Shensi.

Var. euprepes (W. W. Sm.), has spathulate-lance-shaped leaves; flowers vinous-purple or chocolate coloured. South-eastern Tibet.

Culture: Good, somewhat heavy loam, in a damp, open spot, is indicated.

MEGASEAEFOLIA (Boiss.). Megasea-leaved P.
(Megaseaefolia).

A robust, perennial species with a tuft of rounded or oval-rotund, papery leaves, four to six inches long and three to four inches wide, blunt at the tip, heart-shaped or rounded at the base, borne on a narrowly winged stalk about equalling the blade in length; margins furnished with small, sharp teeth; upper surface smooth, underside clothed with rust-coloured down on the nerves. Flower stem slender, more or less smooth, four to five inches tall, bearing one to two superposed umbels of many nodding, rose-coloured blossoms on stalks about three-quarters-of-an-inch long. Corolla about one inch across, divided into five heart-shaped, deeply notched lobes; tube about three-quarters-of-an-inch long, exceeding the calyx. Flowers in March and April. Introduced in 1896. (*Bot. Mag.*, t. 7901).

Grows in damp, shady places on the mountains of Rhasistan and Lazistan, reaching an elevation of about 1,000 feet above sea-level.

Var. superba is a robust garden form.

Culture: Plant it in good, rich loam and leaf-soil, in a shady spot, and keep well supplied with water when in growth.

MEIANTHA (Balf. f.). Small-flowered Fairy P.
(Malacoides.)

A delicate, annual sub-species of P. Forbesii, with a rosette of hairy leaves from half- to one-and-a-half inch long, with oblong, rather blunt blades about three-quarters-of-an-inch long and half-an-inch wide; margins furnished with sinuate, pointed lobes; both surfaces covered with long, jointed hairs; the blade is wedge-shaped at the base and is contracted into a short, distinct stalk. Flower stems many, up to about four inches tall, slender, hairy at the base, more or less mealy upwards and among the flowers, which are borne in solitary or superposed umbels of about fifteen blossoms. Corolla pink or violet, about three-eighths-of-an-inch across; segments broadly wedge-shaped and irregularly toothed; tube cylindrical, short, yellowish, with an obscure ring in the throat. Flowers from January to April.

Grows in damp, shady places on the Maymyo Plateau in the Shan Hills, Upper Burma, at about 3,500 feet above sea level.

Culture: As for P. Forbesii.

MELANODONTA (W. W. Sm.). Detritus P.
(Candelabra.)

A beautiful deciduous, perennial species closely allied to P. serratifolia, with a tuft of broadly lance-shaped or egg-shaped, membranous leaves from one inch to two inches long, rounded or blunt at the tip and narrowed at the base into a hardly distinct, winged stalk; margins rather coarsely toothed; both surfaces more or less smooth. Flower stem four to eight inches tall, smooth, non-mealy, bearing one or two superposed umbels of three to five, slightly fragrant, sulphur-yellow blossoms with a dark, greenish-yellow or orange eye. Corolla about three-quarters-of-an-inch across, with egg-shaped, slightly notched lobes; tube cylindrical, about twice as long as the calyx. Flowers in May and September.

Grows in short turf on alpine slopes and on the muddy banks of streams at Scinghku, in north-eastern Upper Burma, at 11,000 to 13,000 feet above sea level.

Culture: Good fibrous loam in an open spot, saturated with water when the plant is in growth, is indicated. *A. W. Darnell.*

(To be continued.)

HOME CORRESPONDENCE.

Royal Horticultural Society's Accounts for 1928.—I was much interested in your two articles on the R.H.S.'s Accounts for 1928 (pp. 153, 195). Neither Mr. Musgrave nor I is a chartered accountant, although Mr. Musgrave, with his experience in the Land Registry Office, makes a far better treasurer than I could have ever hoped to become. We were both overshadowed by the Gurney Fowler-Reader-Harper complex. Most of the Fellows of the Society, if they keep any accounts at all, do so in penny note-books with what they spend on one side, and what they receive on the other; and to these simple souls the elaborate accounts of the Society are a little confusing. It is, I suppose, necessary to have a Balance Sheet and also Revenue and Expenditure Accounts, but surely the separate accounts of the various trust funds might be omitted or relegated to an appendix. The most serious disadvantage of the accounts in their present form is the impossibility of obtaining much information out of them. For instance, although we have the figures for the hall lettings, we do not know what is the expenditure which they involve in over-head charges, maintenance and upkeep. Again, in the case of the Summer Show, the accounts show on the credit side the excess of receipts over expenditure, but there is nothing in the accounts to show the cost of Chelsea or the total receipts; the figure of £2,630 in respect of the International Exhibition of Garden Design, I understand, is the net figure, *i.e.*, the cost after the receipts have been deducted from the total expenditure on this exhibition. There is something in the nature of a suggestion in the air that the return the Fellows get from Wisley is hardly commensurate with the expenditure of some £15,000 a year. The high cost of Wisley is due almost entirely to the lines on which the gardens have been developed during the years they have been in the possession of the Society; it must be remembered that Mr. Wilson's original garden occupied the few pockets of good soil and well-drained and sheltered land at Wisley, whereas on much of the land taken into cultivation since then gardening is difficult and consequently expensive. I have no hesitation in saying that Wisley is run on strictly economical lines, and that the Fellows get a good return for their money; probably the majority are not aware of this, as I think they have little idea of the immense amount of work done at Wisley in trials of fruits and vegetables. At the same time, I think the Wisley accounts require elaboration, and should show clearly the cost of the different departments; the department under the Keeper of the Gardens, the department under the Keeper of the Laboratories, the department concerned with the fruit trials in connection with the Board of Agriculture, and the farm. With regard to the Lindley Library, I suggest that the list of books acquired in the course of the year should be issued with the *Book of Arrangements* in the same format as the Library Catalogue. *William Lawrence.*

What Shall we do with our Greenhouses—In your issue of March 9, p. 189, Mr. G. H. Everett has broached a subject under the above heading which has occasioned much hard thinking for both employer and gardener since the Great War. Many owners have been placed unwillingly in the position of choosing between demolition, letting, or marketing their own produce, and many private gardeners nowadays are necessarily expected, through force of circumstances, to provide a good surplus for sale, so as to keep these greenhouses and gardens going, and the maximum output is required with a minimum expenditure. The result is that gardeners have to adapt themselves to these changed conditions. Generally speaking, the glasshouses in most private gardens are what I call "odd lots" from a market point of view; they were erected at a time when little consideration was necessary for minimising expenditure. Houses were dotted about in all directions, together with many stokeholes, this being due to the erections taking place over a number of years under various owners and gardeners, who all appear to have had a different end in view. This now resolves itself into an uneconomic system and a drawback to profitable market work. The many stokeholes mean wasted fuel and labour; possibly there is an inefficient water supply, and the houses are unsuitably constructed for market crops. The gardener of to-day who has to make the most from such poor foundations has no easy task, and results are not always satisfactory, if one omits to fully consider these drawbacks. In deciding what crops to grow, it is worth while to give special forethought to the suitability of the houses for any particular crop; the ability to dispose of produce locally, so as to obviate, so far as possible, railway rates, salesmen's fees, and other incidental expenses of a distant market, and also whether the man in charge has special knowledge and skill in the cultivation of any particular crop or plant. The question of heated or unheated houses must be governed by circumstances, but, except in a few instances, unheated houses will not produce crops equal in quantity or quality to houses where artificial heat is available. I agree with Mr. Everett that cold houses will produce excellent crops of high quality Peaches and Nectarines, and my experience has proved cold houses to be more remunerative than heated ones for these fruits. Very high-class fruits of Pears and Plums may be grown easily in unheated houses, but my experience of these as a market proposition is very disappointing. I also agree with Mr. Everett that border cultivation for Plums and Pears is more satisfactory, but I doubt whether it is the more profitable method of utilising a house for that crop. I am inclined to favour the growing of these fruit trees in pots, and after the fruiting period, plunging the trees in the open until it is necessary to bring them under glass again; the house meanwhile could be used for other purposes, and I contend that the increased returns thereby will outweigh the extra labour involved. Tomatos, Cucumbers and Chrysanthemums are, in my opinion, profitable crops for heated houses, and even in cold houses would give a better return than Grapes, which in these days are realising poor prices to the grower; besides which, the vines have to be grown several years before a full crop can be taken from them, and being more or less of a permanent nature they are too risky a speculation. The position of a private gardener of to-day differs greatly from that of his predecessor twenty years ago. He has not the opportunities to foster and experiment with his ideas. He is generally short-staffed, and his expenditure must be kept at the lowest, and he must be continually devising means for economising labour and general expenditure, but must, at the same time, not lower the income. These changed conditions are giving rise to a new type of gardener. There is little opportunity nowadays for training a young man in the details of cultivating such a large range of plants as was the case twenty or thirty years ago, and I see little hope of this generation producing men the equal of the grand old experts of bygone days. Nevertheless, we shall always have our experts in accordance with the moving times; the brains are as good as ever and will be diverted to other channels, and if our aim is "progression," we shall be striving for something worth while. *W. F. Baker, Melton Constable Park Gardens.*

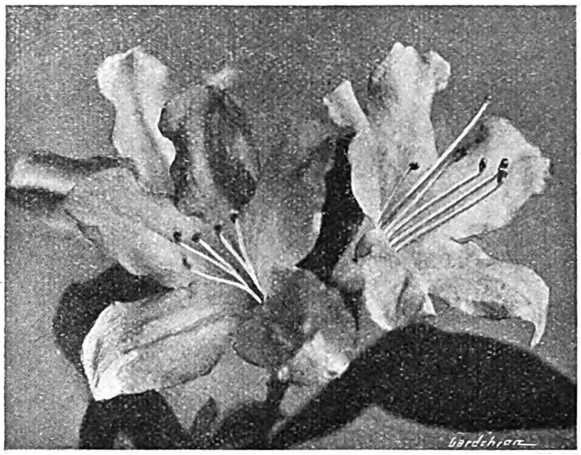

FIG. 129.—AZALEA MATSUKAZE

A variety representing a new race entitled Kurumesatsuki.

(See p. 245).

Rabbit Breeding for Fur.—Gardeners usually regard rabbits as a nuisance, but at a time when everyone is looking forward to a revival of prosperity and every avenue of progress is being carefully explored, the unquestionable opportunities offered by breeding rabbits for fur should not be overlooked. To those who, even now, after some years of established success, remain unconvinced of the profits to be obtained from this source, it may come as a surprise to learn that the Fur Board is paying 10s. 6d. each for first-grade Chinchilla and Sable pelts, and 8s. 6d. each for Havana, Argente and similar furs. It must also be remembered that the Fur Board buys for re-sale at still higher prices. Scientific and practical tests carried out at the Harper Adams Agricultural College have proved that the total cost of feeding these rabbits on concentrated foods at commercial prices (which is naturally more expensive than when the breeder relies mainly on surplus garden or farm produce), from birth to an age suitable for pelting, does not exceed 4s. each, and this sum will in many cases be reimbursed by the sale of the carcase alone. There can be few hobbies or side-lines which show such a handsome return as this, and I think if the fact were more widely known, many people in town as well as country, would be able to add to their incomes, and that of the nation, by producing natural rabbit furs on a much larger scale. *E. Bostock Smith, Heaselands, Canterbury.*

Apple Adams's Pearmain.—Referring to the article by *A. Petts* (March 16) on Apple Adams's Pearmain, I had this variety under cultivation for several years at Bussock, Newbury, and found it one of the best late sorts, but only so when left on the tree until very late in the autumn. As regards its origin I see it is referred to by R. Dean in *Gard. Chron.*, April 6, 1901, p. 213, as follows:—"To the first half of the nineteenth century we owe the production of such varieties as Adams's Pearmain, Cox's Pomona, Cox's Orange Pippin, raised from seed in 1830, although not distributed until several years afterwards." Judging by its flavour, it is probably a cross between Ribston Pippin and Winter Queening. Another late variety which I think is almost as good is Baxter's Pearmain; with me both were good and regular croppers. *W. H. Clark, Cornford House Gardens, Pembury, Kent.*

Gardeners' Pay and Status.—The only way to raise the status and pay of head gardeners and men throughout the British Isles, is for those concerned to become members of the Professional Gardeners' Association, form local branches, and arrange monthly lectures for the furtherance and experience of the under-gardeners. For particulars and rules, apply to Mr. G. Reid, Secretary, Pollard Hall Gardens, Gomersal, Leeds. *F. Capp, Nostell Priory Gardens, Wakefield.*

EXPERIMENTS ON THE CONTROL OF THE CARROT, ONION, AND CABBAGE ROOT FLIES.

Some of the earliest records of the damage done to crops by insects in this country concern flies attacking various vegetables. In the middle of the last century Curtis recorded their prevalence, and in the annual reports compiled by Miss Ormerod reference is frequently made to them.

The life histories of these flies have been gradually worked out and, from 1920 to 1925, K. M. Smith, at Manchester University, made observations upon them and carried out experiments with a view to preventing the damage done by these pests.

Experimental work in this direction has chiefly aimed at the discovery of some suitable substance which would act as a repellent to the flies, so that when applied to the soil near the plants, the smell would be capable of deterring the female fly from laying eggs there. This, indeed, seems to be the most hopeful line of work, since it is well-known that once the eggs have hatched and the larvae have commenced to feed, very little can be done to counteract the attack. The old remedies of lime and soot, or sand impregnated with paraffin, scattered among the plants, were probably partially effective in keeping off the flies, but Smith, in his experiments, employed a great variety of aromatic compounds, some of which showed considerable promise.

Since the loss due to these attacks is so widespread it was thought advisable to carry out experiments in as many parts of the country as possible in order to obtain definite information on the relative value of certain recommended substances. A scheme was accordingly prepared and the experiments carried out by entomologists at many Agricultural Colleges and University Departments throughout the country. The results here given are those of the experiments carried out in Staffordshire by the writer, who at that time was stationed at Harper Adams Agricultural College, Newport, Shropshire.

In that area, the three flies concerned are perennially responsible for a very great amount of damage, not only in gardens, but in the field. The facilities for the experiments were obtained in school and evening-school gardens, where the work could be carried out under very careful supervision, and the data kept with the greatest possible accuracy. The following details concern the treatments given to the plots, and the rate at which the substances were applied. The plots were all separated from each other by a narrow path, and were duplicated in order to obviate, so far as possible, differences due to situation and soil conditions.

The Carrot Fly.

Variety.—James' Scarlet Intermediate.

Cultivation, etc.—Seeds sown thinly at the usual time for the district on deeply worked soil. No fresh manure or fertilisers applied. Plants were singled to six inches so soon as large enough to handle, and all those pulled out were destroyed. Inter-cultivation was practised as required.

Experimental treatments:—

1. Creosote and precipitated chalk, 1:100. 2 oz. of the mixture per square yard.

2. Nicotine sulphate (40 per cent. Nicotine) and precipitated chalk, 1:12. 2 oz. (approximately) per square rod.

3. Naphthalene (Grade 16). 2 oz. per square yard.

Three applications in each case:—(1) About 10 days before thinning (May 10, approximately); (2) at thinning (May 20 approximately); and (3) about 10 days after thinning (May 30, approximately).

	% Clean Plants.
Nicotine sulphate ...	= 59·3
Naphthalene	= 79·8
Creosote	= 59·8
Untreated	= 56·8

Note.—A. and B. represent duplicated plots.

Discussion of Results.

The untreated plots yielded an average of rather more than fifty per cent. of clean plants, and this figure was not materially improved upon by either the creosote or Nicotine sulphate treatment. Naphthalene gave easily the best yield of clean roots, an average of nearly eighty per cent. It is most significant to record, here, that the untreated plots, especially at Stafford and Wombourne, gave a much better yield of clean plants than is usual. The writer was told, in fact, that certainly for the past twenty years no good Carrots had been grown in the garden at Wombourne, and even the crop of the untreated plot was regarded as good. In the same garden, about twenty yards from the experimental plots, were other small beds of Carrots, and these were a complete failure, not one good Carrot being found. Some explanation is therefore needed for the good result on the untreated plots in the trial. Here the plots were separated only by a path two feet wide, and it is almost certain the smell of naphthalene was sufficient not only to keep off the flies from the plot treated with that substance, but also to protect adjacent plots in some measure. Had the untreated plots been removed a considerable distance from the naphthalene plots, it seems almost certain that they would have produced only a very poor crop.

The Onion Fly.

Variety.—Cranston's Excelsior.

Cultivation, etc.—Seeds sown thinly in drills on the plots in spring, and plants thinned to six inches apart when large enough to handle. All plants pulled out were destroyed.

Experimental treatments:—

1. Chlor-cresylic acid and precipitated chalk, 1:100. 2 ozs. per square yard.

2. Naphthalene (Grade 16). 2 ozs. per square yard.

3. Nicotine sulphate (40 per cent. Nicotine) with precipitated chalk, 1:12. 2 ozs. per square rod.

Three applications in each case:—(1) May 20, approximately; (2) May 30, approximately; and (3) June 10, approximately.

With the exception of corrosive sublimate (mercuric chloride), all the substances employed were in the form of fine powders, and were very easily applied by means of a tin with a perforated lid. Such applications can be very rapidly carried out, and involve little extra time and labour. In arriving at the results, every individual plant was lifted and examined. The dates shown for the times of application of the substances under trial are only approximately accurate and varied with each individual centre according to weather conditions and time of sowing.

Onion Fly Experiments.

Average for all Centres.

		% Clean Plants.
Chlor-cresylic acid	=	56·5
Naphthalene ...	=	67·0
Nicotine sulphate	=	43·6
Untreated ...	=	50·3

Note.—A. and B. represent duplicated plots.

Discussion of Results.

As with Carrot fly, naphthalene has given the greatest measure of control, although in a less marked degree. Nicotine sulphate seems to have been quite unsuccessful, and owing to its cost and the small rate at which it can consequently be applied, it must be regarded as unsatisfactory.

This is rather a puzzling result, since Smith in his experiments in Cheshire, regarded Nicotine sulphate as a very promising substance against

Onion fly. He, however, used a five per cent. mixture with chalk, and made about ten applications during the growing season. At all centres the crop was regarded as very satisfactory, but the attack by the fly was not so severe as in some seasons.

The Cabbage Root Fly.

Variety.—Veitch's Autumn Giant Cauliflower.

Cultivation, etc.—Plants raised from seeds at each centre and well planted, so far as possible in favourable weather. Inter-cultivation as required.

Experimental treatments :—

1. Creosote and precipitated chalk, 1:100. ¼-oz. per plant (approximately).
2. Chlor-cresylic acid and precipitated chalk, 1:100. ¼-oz. per plant (approximately).
3. Corrosive sublimate solution, 1 oz. in 8 gallons. ¼-pint per plant (approximately).
4. Naphthalene (Grade 16). ¼-oz. per plant (approximately).

Three applications in each case :—(1) At the time of planting out; (2) about ten days after planting; and (3) about twenty days after planting.

Cabbage Root Fly Experiments.

Centre.	°/₀ Healthy Plants.	°/₀ Attacked Plants.	Treatment.
Stonnall ... ... Examined at intervals up to September 3	76	24	Untreated.
	62	38	Naphthalene.
	86	14	Creosote.
	46	54	Chlor-cresylic acid.
	95	5	Mercuric chloride.
Willenhall ... ... Examined at intervals up to September 6.	89	11	Untreated.
	100	0	Naphthalene.
	99	1	Creosote.
	98	2	Chlor-cresylic acid.
	99	1	Mercuric chloride.

Discussion of Results.

At both centres, the mercuric chloride treatment was successful in giving a good plant, although it has certain disadvantages in use. It is a poison, and must be used with care, only by capable people. It should be kept under lock and key, and well labelled, so that it cannot be mistaken for any other substance. The application involves making a solution which is a more lengthy process than applying a dry powder. Despite these drawbacks, however, it has an additional advantage on land infected with Plasmodiophora brassicae, the club root fungus, in that at the strength used it also gives a very good control of this disease.

With regard to the other substances used, little information can be drawn from the results of the plots at Willenhall, since the attack there was slight. At Stonnall, creosote gave a promising control and resulted in more good plants than any other treatment except mercuric chloride. Naphthalene here was not encouraging, though at Willenhall it was actually the best plot. Careful examination of the Stonnall plots, however, showed that failures with naphthalene were largely due to a scorching effect on the plants, and it accentuated the very dry soil conditions then existing. The failures nearly all occurred immediately after planting, and are not attributable to the fly attack. It is probable, therefore, that this substance must be used with discretion in dry periods, and not allowed to remain in a heap on the soil immediately around the plants.

It is interesting to note, here, that Mr. F. R. Petherbridge, of the School of Agriculture, Cambridge, obtained excellent results with naphthalene in his experiments, the treated plot being almost free from attack, while the mercuric chloride plot was second best. *S. G. Jary, B.A., Advisory Entomologist to the Southern Province, The University, Reading.*

POTATO FUTURES.

I have been interested in growing, buying and selling Potatos for forty years, and think the time has come for taking stock of what has been done, and forcasting what should be done.

In the 'eighties and 'nineties of last century, such well known varieties of Potatos as Abundance, Beauty of Hebron, Duke of York, Epicure, Sharpe's Express, Snowdrop, Up-to-Date and British Queen, were introduced and many of them continue to this day.

In the first ten years of the present century Findlay's varieties were rapidly taking first place and were followed by Mackelvie's and others —Golden Wonder, Great Scot, King Edward, Ally, Majestic, Arran Chief, Arran Victory and Kerr's Pink.

Wart disease existed in Shropshire and Staffordshire prior to 1901. In 1908 systematic work was begun at the Harper-Adams College, Newport, by Mr. G. T. Malthouse. In that work the Board of Agriculture and Fisheries took an interest. One of their inspectors, Mr. G. C. Gough, had discovered that the variety Snowdrop was immune to wart disease; soon other varieties were also found to be immune to this terrible plague.

Shortly thereafter, the Board of Agriculture and Fisheries started investigational work of its own at Ormskirk, with the late Mr. John Snell in charge. Mr. Snell was a brilliant original worker, and things moved rapidly. A policy was formulated and infected areas were scheduled. Varieties susceptible to wart disease were not allowed to be planted in such areas, and that has been the policy in practice up till the present, with slight modifications. It must be recorded as successful; the spread of wart disease has been stayed.

Concurrent with the policy of control carried on officially by the Government, raisers turned their attention to discovering and raising varieties which were immune to Wart disease. Sutton's Abundance and its many synonyms were found to be immune and useful; so were Golden Wonder and Kerr's Pink. New varieties, such as King George, Ally, Great Scot and Majestic appeared on the market but nothing has come along to take the place of Duke of York (and its synonyms), or British Queen, King Edward, Up-to-Date and Arran Chief.

It is here I am going to strike in with my suggestions. Officially, for a number of years, no new variety has been recognised or encouraged in any way unless immune to Wart disease. Raisers are invited to send seedlings to the Ministry of Agriculture's Station, Ormskirk, or to the Scottish Department of Agriculture's Station at East Craigs, in their second year, to be tested for wart disease. Single tubers are accepted, so that the owner may know at the earliest stage possible if the new variety is immune. The result of this has been that every seedling which did not stand up to the official immunity test was destroyed.

In face of the fact that under 100,000 acres out of a total of 2,500,000 acres of Potato land are scheduled as infected areas, I hold that raisers should develop the very finest of their non-immune varieties. These 2,400,000 acres are calling for successors to King Edward, Up-to-Date, Duke of York and Arran Chief, and so are the British public.

There is something about these old varieties which has not yet been attained in the immune varieties. I do not suggest that the Government should take up the testing of susceptible varieties, but I do propose that raisers and introducers should pay attention to *their very best* non-immune seedlings, and develop them with a view to introduction. It can be done without the patronage of the authorities, and will be good policy for the Potato industry.

Remember that wart disease is now held well in check, and that the best authorities declare that virus diseases are far more serious to-day than wart disease, and are in no way mixed up with the problem of wart disease. *William Cuthbertson.*

FRUIT REGISTER.

STURMER PIPPIN.

Pomologists are busy in their efforts to remedy the scarcity of good late dessert Apples, but recent introductions will have to be tried for some years under varying conditions before it can be stated confidently that the century-old Sturmer Pippin has been superseded.

It makes an excellent bush of compact habit, comes into bearing early and bears regularly, being one of that comparatively small number which are self-fertile. In a cold season it is apt to be of poor quality and texture, as it requires a long season to mature, for which reason it is not altogether satisfactory in a cold soil or situation. Such a late variety should obviously be allowed to retain its fruits so long as possible, and I have gathered it so late as December 12, after a wet autumn, without avoiding shrivelling. To keep the fruits in good condition until May, or even later, they should be stored in boxes between layers of paper, always delaying this for a week or two after picking. The fruits are always pleasantly acid, but with a very distinct flavour at their best.

Although so late in maturing, Sturmer Pippin is one of the earliest to come into flower. It is one of the few varieties with fruits of a brown or bronze colour in a good season, with just a touch of russet; the fruits are of medium dessert size, five or six to the pound when full grown. *A. Petts.*

PUBLIC PARKS AND GARDENS.

The Parks Committee of the County Borough of Dewsbury has decided to form a putting green at Rock House Recreation Ground, and also to convert its grass tennis courts in the County Borough of Dewsbury into hard ones.

The Twickenham Town Council is considering proposals for the laying out of the Orleans House frontage and the provision of an open-air swimming pool.

The Egham Urban District Council has accepted a gift of sixteen acres of land at Ankerwyke Corner, Egham, with buildings and a sum of £200 towards the erection of a bathing pavilion; also the seven acres of land near Glanty Corner, Egham, for a children's recreation ground.

The Southampton Town Council has decided to take steps to acquire certain portions of the Itchen River frontage at Bitterne Park for a recreation ground.

A Sub-committee of the Parks Department of Edinburgh Town Council had before them recently a proposal by Councillor Wilson McLaren that the Corporation should acquire as a public park the farm of Swanston, including Swanston farm cottage and village, also the hillside of Caerketton and Allermuir; it was decided to delay the matter to enable the Committee to visit the ground.

The Bournemouth Town Council has received sanction to borrow £37,500 for the extension of the West Undercliff Promenade and £7,500 for the new pleasure grounds at Iford.

The Llanelly Town Council has authorised the Town Clerk to take steps to raise a loan of £38,385 for the town centre scheme, which includes the lay-out of a three-acre site opposite the Town Hall as an open square.

The Ministry of Health held an enquiry recently into an application by the Colwyn Bay Urban District Council for sanction to borrow £2,100 for the purchase of land at Bronnant for various purposes, including the establishment of a nursery for the propagation of plants.

SOCIETIES.

ROYAL HORTICULTURAL.

March 26 and 27.—There was a particularly bright show in connection with the fortnightly meeting of the Royal Horticultural Society on these dates. The New Horticultural Hall was fairly well filled with a pleasant variety of spring flowers, with a sufficiency of fruits and vegetables to make it a representative show. Orchids were again shown in quantity and of especially good quality. As before, the useful Cymbidiums predominated, but there were also many plants of Oncidium, Cattleya, Cypripedium and other genera. The Orchid Committee recommended two First Class Certificates and seven Awards of Merit to novelties. Alpines were shown in greatly increased numbers and nearly all were of first-rate quality. Forced shrubs of various kinds, Carnations and Roses were prominent. The Floral Committee recommended three Awards to novelties. The new Sewell Medals, for alpines in pots or pans, were won by Messrs. Casburn and Welch in the trade class, and by C. Kirch, Esq., in the amateur class. In spite of the difficulties of the season, Daffodils were quite good, and the several large displays added to the brightness of the show. The Daffodil and Tulip Committee recommended one Award of Merit to a novelty. The Fruit and Vegetable Committee made no award to novelties, but in the hall there were good collections of vegetables and of Apples.

Orchid Committee.

Present : Mr. Fred J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Secretary), Prince Shimadzu, Sir John Rutherford, Mr. S. Low, Mr. Robert Paterson, Mr. T. Armstrong, Mr. A. McBean, Mr. Fred. K. Sander, Mr. Charles H. Curtis, Mr. A. Dye, Mr. H. G. Alexander, Mr. T. W. Taylor, Mr. W. H. Hatcher, Mr. S. Flory, Mr. J. E. Shill, Mr. H. H. Smith and Mr. J. Cowan.

First Class Certificates.

Brasso-Cattleya Prince Olaf (*C. Prince Shimadzu* × *B. C. Nena*).—A splendid Orchid with very large and broad, rosy-mauve petals and paler sepals. The big, bold lip is bright violet-purple with a frilled, mauve edge, and pale gold throat. Shown by Messrs. Black and Flory.

Laelio-Cattleya Titymoma (*C. Tityus* × *L.-C. Momus*).—A beautiful hybrid of fine proportions and ample size. The fringed petals are rosy-mauve, as are the petals, but the latter are a trifle paler. The lip is very shapely, frilled purple, shaded with royal purple and margined with mauve at the front, and with a veined, old-gold throat. Shown by Messrs. Cowan and Co.

Award of Merit.

Cymbidium Marabou, Exbury var. (*C. insigne* × *C. vesta*).—A very dainty variety, with flowers of the purest white, except for pale pink dottings and a very pale lemon-yellow crest on the lip. Shown by Lionel de Rothschild, Esq. (grower Mr. B. Hills), Exbury, Southampton.

Miltonia Nadia var. Helen Paterson (*M. Charlesworthii* × *M. Princess Margaret*).—A lovely variety with the lip and petals of a soft clear rosy-mauve shade; sepals much paler, shading to white at the tips; the mask on the lip is soft yellowish-brown with a white margin. Show by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, Sussex.

Miltonia Lucia var. Molly Paterson (*M. vexillaria* × *M. Princess Margaret*).— In this large-flowered form the petals are deep purple with white tips; sepals white with pale mauve purple marks at the base. Lip large, white, flushed with purple below the white-rimmed, red-brown mask. Shown by Robert Paterson, Esq.

Cymbidium Plover, Wyld Court var. C. Lowio-grandiflorum × *C. Pauwelsii*).—This bold Orchid is very like a fine form of C. Lowianum. The sepals and petals are green and the lip is creamy-white with deep red-brown markings. Shown by Sir W. Cooke, Bart. (gr. Mr. H. Butcher), Wyld Court, Hampstead Norris, Newbury.

Odontioda Velasquez (*O. Coronation* × *O. var. unknown*).—A hybrid of good form, but with the flowers rather too closely set on the spike. The petals are red on a cream ground and have purplish margins; the sepals are similarly coloured, except that they have mauve-purple apices. Lip small, pale mauve, red and gold. Shown by Gus Mayer, Esq. (gr. Mr. R. Cottam), Wistlers Wood, Woldingham.

Cymbidium Vesta var. sanguinolentum (*C. Alexanderi* × *C. insigne*).—In this distinct form the blush sepals and petals are flushed with pink and the blush lip is heavily marked with blood red. Shown by Messrs. Stuart Low and Co.

Cymbidium Puffin var. Calypso (*C. Dryad* × *C. Martin*).—A small flower, but very distinct. The sepals and petals are milk-white, with rose-tinted upper margin, while the white lip is heavily marked with deep velvety red. Shown by Messrs. H. G. Alexander, Ltd.

Groups.

Cymbidiums were once again a great feature of the groups of Orchids which extended the whole length of one side of the new hall.

Sir Jeremiah Colman Bart., (Orchid grower Mr. B. Perfect), Gatton Park, Reigate, contributed a delightful group wherein Brasso-Cattleyas were particularly good, these including B.-C. Gatton Lily, very fine; B.-C. Mildred, B.-C. Speciosa var. Lady Colman, B.-C. Gatton Lily var Triumph, B.-C. Gatton Snowflake, and B.-C. Cliftoni var, magnifica; Cattleya Cowanae; alba, and L.-C. Eldorado, were also very fine, while Cymbidiums were an excellent background to a grand display and along the front were such interesting Orchids as Cymbidium Devonianum, the long Sophro-Laelia Marriotiana, Epidendrum Endresii, Sarchochilis Hartmannii, Megaclineum purpurio-rachis, Polystachya paniculata, Coelogyne pulchella, C. sparsa, Masdevallia xanthina, and Leptotes bicolor.

Messrs. Sanders displayed a small forest of Cymbidium spikes borne by excellent plants. A few of the finest were C. Erica Sander var. Sunstar, C. Alexanderi var. The Gem, C. Adonis var. Dawn, C. Nelly, C. Unique, and C. Louise var. Perfection. Grouped with these and other fine varieties were Cattleya Avalanche, and Laelio-Cattleya John Waterstraedt, of fine colour; Brasso-Cattleya St. Andre, Lycaste Balliae var. Mary Gratrix, Oncidium pubes, Masdevallia civilis and Pleurothallis Roezlii.

Odontoglossums were finely displayed by Messrs. Charlesworth and Co. O. Matador made an excellent centre-piece, and on either side were long spikes of O. crispum in variety, O. Pyramus, O. Laurentia, O. Princess Yolande and O. xanthinum. Odontiodas were represented by O. Vivienne, O. Nanette, O. Pittae, O. Ronx and O. Chanticler. Besides all these good things the Haywards Heath firm exhibited Pholidota convallaria, Epidendrum Endresio-Wallisii, Cirrhopetalum picturatum and the old Masdevallia Shuttleworthii.

Messrs. J. and A. McBean had Cattleya Jupitus in fine condition, the spike carrying four glorious flowers; Miltonia Bleuana rosa was also fine, as were Cymbidium Alexanderi var. roseum, C. Pearl, C. Pauwelsii, C.Arabella, the effective. Oncidium McBeanianum, Odontioda Lambeauianum and the quaint old Arpophyllum giganteum.

Messrs. Stuart Low and Co. had a bright display of Dendrobrium Brymerianum, D. Pierardii, Laelio-Cattleya Illustrious, L.-C. Sladdeni, L.-C. Leemaniae, L.-C. Luminosa, Sophro-Laelio-Cattleya Beta, S.-L.-C. Edith Tack, and several Cypripediums.

Mr. J. Evans showed fine specimens of Platyclinis glumacea, Dendrobium Thwaitesiae D. Pierardii and Cymbidium Alexanderi.

Floral Committee.

Present : Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. R. B. Long, Mrs. Ethel M. Wightman, Rev. Rollo Meyer, Mr. Donald Allan, Mr. J. R. Riding, Mr. Courtney Page, Mr. R. Findlay, Mr. W. B. Gingell Mr. C. F. Langdon, Mr. J. M. Bridgeford, Mr. D. B. Crane, Mr. Charles E. Pearson, Mr. G. W. Leak, Mr. William Howe, Major George Churcher, Mr. M. Allwood, Mr. E. R. Janes and Mr. W. F. Cartwright (Secretary).

Section B.—Mr. Charles T. Musgrave (in the chair,) Mr. E. A. Bowles, Mr. W. G. Baker, Mr. W. J. Bean, Mr. G. Reuthe, Mr. W. B. Cranfield, Mr. Reginald Cory, Mr. C. W. Williams, Mr. R. C. Notcutt, Mr. G. Yeld, Lady Beatrix Stanley, Mr. Gerald W. E. Loder, Sir William Lawrence, Bt., Mr. T. Hay, Mr. A. Bedford, Mr. F. J. Preston, Mr. L. R. Russell, Mr. Clarence Elliott, Mr. J. Comber and Mr. N. K. Gould, (Secretary).

Awards of Merit.

Leucocoryne ixioides var odorata.—In general appearance this Liliaceous plant is much like a giant Glory of the Snow (Chionodoxa Luciliae) with the added merit of delicious fragrance. The blue and white flowers are borne on slender, graceful stems nearly two feet in length. The species was illustrated as Brodiaea ixioides in *Bot. Mag.*, tab. 2382. It is a native of Chili, where the present exhibitor collected bulbs last year. Shown by Mr. Clarence Elliott.

Rhododendron euchaites.—Forrest No. 12125. Kingdon Ward, No. 3040. A brilliant truss of medium-sized, shining ruby-red flowers with a large, collar-like calyx of the same colour. The leaves are rich green and relatively small. Shown by Lady Aberconway (gr. Mr. F. C. Puddle), Bodnant, North Wales.

Rhododendron Delight.—A hybrid of R. praecox and R. ciliatum. A vigorous spreading bush, with neat foliage midway between the two parents, and bearing an abundance of flowers, was shown. The flowers, which are in trusses of pairs and occasionally threes, are rather smaller than those of R. ciliatum,and of beautiful apple blossom-pink flushing. Shown by Messrs. R. Gill & Son.

For Trial at Wisley.

Primula Peakland Beauty.—A very floriferous blue Primrose. The flowers were all pin-eyed and had a good rich yellow zone. Shown by D. B. Milne, Esq., Sabine Hay, South Darley Matlock.

Groups.

No doubt in view of the new competition for the Sewell Medals, alpines were extensively shown, and there were many very beautiful plants on view. In the competition the trade medal was won by Messrs. Casburn and Welch, who staged lovely plants of Saxifragas Burseriana Gloria, Burseriana sulphureum, Irvingii, Jenkinsii and Paulinae, and Primula Allionii. C. Kirch, Esq. (gr. Mr. G. Harris), Edenhall, Beckenham, had the best of four amateur collections and was awarded the medal for especially good plants of Saxifragas Burseriana speciosa, lilacina, Faldonside Allionii and its white variety, and Shortia uniflora grandiflora R. Bevan, Esq., Crowsley Grange, Henley-on-Thames, had excellent plants of Androsace ciliata and Fritillaria karadaghensis in his exhibit.

An extensive collection of excellent alpines in large pans and pots was staged by Mr. Clarence Elliott, who included magnificent plants of various Saxifrages including the varieties Jenkinsii and Griesbachii Wisley, var., Crocuses and Muscari. Messrs. M. Prichard and Son filled considerable table space with batches of Androsace sarmentosa, Salmont's variety, Anemone fulgens, Primula rosea and other alpines. Messrs. Casburn and Welch, had a rock garden planted with alpines and dwarf Conifers, and Messrs. Tuckers planted their rock garden with appropriate plants.

A length of tabling was filled with alpines in pots and pans by C. Kirch, Esq. (gr. Mr. G. Harris), Edenhall, Beckenham, who had particularly good specimens of Saxifraga Jenkinsii, S. Griesbachii, Wisley var., S. His Majesty, S. lilacina, Primula Allionii and Androsace pyrenaica. Messrs. Patrick's grouped Acacias and Conifers behind a low rockery planted with alpines. Adjoining their Apples, Messrs. J. Cheal and Sons set out a good exhibit of alpines.

The Rev. Rollo Meyer (gr. Mr. J. P. Izzard), Watton Rectory, Hertford, showed masses of Iris reticulata, I. Cantab and vases of Viburnum fragrans. Messrs Barr and Sons had an exceedingly attractive rock garden exhibit with breadths of Hepatica angulosa, Iris reticulata, Cyclamen Coum, Fritillarias and Erica carnea. Messrs. Pulham and Son made a small sandstone rock garden. Mr. George G. Whitelegg showed Rhododendrons, deciduous Azaleas and alpines, and Mr. George E. P. Wood had a display of alpines. With a background of floriferous double Cherries, Messrs. D. Stewart and Son grouped Hyacinths, Daffodils and Muscari. The Misses Hopkins had a neat little rock garden exhibit. Mr. Gavin Jones used Saxifrages, Drabas, Ericas and Conifers effectively, while Messrs. W. H. Rogers and Son gave prominence to Prostranthera rotundifolia amongst the alpines in their exhibit. Messrs. Hodsons associated alpines with Rhododendrons and Mr. F. Therkildsen planted Sempervivums, Saxifrages and other lowly plants in his rock garden.

In an attractive display, Messrs. Waterer, Sons and Crisp grouped Rhododendron caucasicum, R. Handsworth Scarlet and Osmanthus Delavayi in association with early spring flowers and alpines. In a well-arranged exhibit, Messrs. W. Cutbush and Son displayed double-flowered Cherries, Laburnums and Azaleas. In a large floor group, Messrs. L. R. Russell, Ltd., displayed various flowering shrubs, including a good collection of Clematis and Azaleas. Messrs. Hollamby had large bushes of Hamamelis arborea and the dwarf Gaultheria procumbens. Mr. G. Reuthe had an interesting collection of plants and shrubs with trusses of Rhododendrons.

An admirable collection of shrubs was arranged by Messrs. Robert Veitch and Son, who included large sprays of Magnolia salicifolia, M. Lennei, M. Alexandrina, Raphiolepis Delacourii, Kurume Azaleas and several particularly good Camellias. In a corner space, Messrs. R. Gill and Son showed several large bushes of Rhododendrons, including the new varieties Delight, and ample sprays of R. Cornubia, R. Bernard Gill, R. argentea and Magnolia Campbelli. In another place, they set up many spathes of Richardia africana and Anemones.

The Duke of Wellington (gr. Mr. H. J. Beckenham), Ewhurst Place, Basingstoke, contributed a well-arranged group of dark blue stellata Cinerarias, Hymenocallis (Ismene calathina) and Iris fimbriata. The Hon. Marshall Brooks (gr. Mr. A. Carter), Portal, Tarporley, Cheshire, had a dozen or more magnificent plants of varieties of Clivia miniata; Messrs. Dobbie and Co. staged many splendid plants of large-flowered Cinerarias which illustrated a desirable strain of first-rate cultivation. Mr. G. H. Dalrymple again had a large collection of his coloured Freesias. Messrs. Stuart Low and Co. grouped Anthuriums, Hippeastrums, Acacias and Azaleas, and on the floor had some large bushes of Camellias.

Particularly good cut Roses were shown by Mr. George Prince and Mr. Elisha J. Hicks. The former had large vases of I. Zingara, Shot Silk and Etoile d'Hollande in his collection; while the latter included Mrs. H. Stevens, Charles E. Shea and Angèle Pernet of good quality. Their usual first-rate collections of Carnations were staged by Messrs. C. Engelmann, Ltd., Messrs. Stuart Low and Co., and Messrs. Allwood Bros. Lady Brodie Henderson (gr. Mr. W. Eggleton), Epping House, Hertford, sent over a dozen vases of distinct varieties of Sweet Violets of considerable merit. Mr. Baldwin Pinney also showed good Violets.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mr. G. W. Leak, Mr. G. Monro, Mr. P. D. Williams, Mr. Peter R. Barr, Mr. W. B. Cranfield, Mr. H. Smith, Mr. H. G. Hawker, Mr. J. S. Arkwright, Mr. L. G. Richardson, Mr. G. L. Wilson, Mr. A. W. White, Mr. F. A. Secrett, Mr. Charles H. Curtis, Mr. J. D. Pearson, Rev. Rollo Meyer, Mr. F. Barchard, Mr. G. Churcher, Mr. W. F. M. Copeland, Mr. W. Poupart, and Mr. A. Simmonds (Secretary).

Award of Merit.

Narcissus Whiteley Gem.—A grand Incomparabilis variety of fine substance and colouring, exhibited as a show flower. The bloom is about three inches across, with spreading, broad perianth, segments of rich primrose-yellow, the tubular cup about one inch long and spreading and crinkled at the mouth, being apricot coloured, paler at the throat and enriched with orange at the edge. The blooms were borne erect on long, slender, but firm stems. Shown by R. F. Calvert, Esq., Coverack, Cornwall. It was raised by Mrs. Brodie of Brodie.

Groups.

Narcissi and Tulips were shown fairly extensively at this meeting, the former especially being represented by several grand collections. Messrs. J. R. Pearson and Sons had a fine bank of Narcissus blooms, representing many different types. At the back, fine large Trumpet sorts, as the giant Tresserve, King Alfred, Van Waveren's Giant and Victoria were in evidence, while other choice Trumpet varieties which demanded attention were Vestan, rich yellowish-cream trumpet and palest cream perianth segments; The Don, of similar colouring but a trifle richer in the trumpet; White Dame; Elfrida Pearson, very dainty; and Weardale Perfection. Numerous Incomparabilis Narcissi were represented, and there were very attractive vases of Narcissus Odorus var. rugulosus. Among the many outstanding sorts other than Trumpet varieties were Bernardino, Homer, Whitehall, Brilliancy, Sunrise and Croesus, together with several striking seedlings.

Messrs. Barr and Sons had a massed collection of Narcissi, in which were magnificent sheaves of the richly coloured Sunrise; the frilled and waved, rich golden Trumpet variety maximus, and Yellow Standard. The double-flowered Primrose Phœnix was well shown, and other notable sorts in this group were Winter Gold, Ptolemy, very fine; King Alfred, Beersheba and Sweet Adare. At the front of the display were groups of flower spikes of numerous named varieties of Lachenalias of very good quality.

Another very interesting collection of Narcissi was set up by Mr. J. L. Richardson, in which large Trumpet sorts were the dominant feature. There were magnificent blooms of the lovely Beersheba, other pale coloured sorts being Moira O'Neill, Mitylene, White Nile, White Emperor, Zionist, Marquis of Headfort, and the dainty Winsome; among rich golden-yellow Trumpet varieties the most striking were the magnificent Golden Chariot, Music Hall, Golden Prospect, Luxor, Arcs, Blaencona and Roko. Other sorts of outstanding merit in this well-staged group were Fortune, an Incomparabilis of rich colouring and fine texture; the popular Sunrise, Croesus, Glorious, Firetail and White Sentinel. There were also several good seedlings, unnamed.

Mr. G. L. Wilson showed a large number of the newer varieties of Narcissi, among which the most prominent were Beersheba, very fine and in splendid condition; and the lovely creamy-white, beautifully-shaped White Emperor, together with White Nile, Hymettus and Eskimo, all Trumpet sorts of similar colouring; the giant Kantara, Tenedos and the rich yellow King of the North. Mitylene was shown well, and there were also good blooms of Raider, Hispodar and Satellite.

In conjunction with their exhibit of dwarf spring bulbs and flowering shrubs, Messrs. D. Stewart and Son had a small collection of Narcissi, in which we noted good vases of Mrs. Martin Stewart, stated to be a Triandus hybrid, of large size considering its parentage and of palest cream colouring; Tony, a very charming giant Leedsii variety; Orange Cup, Buttercup, Mrs. E. H. Krelage and Lord Kitchener.

Near the centre of the hall, Messrs. R. H. Bath, Ltd., had a tastefully arranged floor group of Tulips in bowls, among the most striking of the many varieties displayed being La Reve, Dom Pedro, Zulu, Blue Bird, Pride of Haarlem, Eclipse, Bartigon, the golden-yellow W. T. Ware, La Tulipe Noire, Farncombe Sanders, Zanzibar and Faust; they also had a few bowls of Hyacinths.

Messrs. G. W. Miller had a mixed collection of Tulips, Narcissi and Hyacinths, together with other spring flowers, such as Primroses in variety, Saxifrages and Pulmonarias. Among Tulips, the outstanding sorts were the double-flowered El Toreador, Rising Sun, Pride of Haarlem, Prosperity and Couronne d'Or, while noticeable Narcissi were Comrade and Bernardino.

An interesting exhibit demonstrating the Cornish methods of marketing Narcissi and Broccoli was set up under the auspices of the Cornwall County Council, and attracted a good deal of attention. The Narcissi were in grand condition and magnificently packed, while the Broccoli were packed in crates as despatched to the markets, which now embrace Continental so well as British ones.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. J. Cheal, Mr. W. Poupart, Mr. Edwin E. Beckett, Mr. T. Pateman, Mr. E. Neal, Mr. J. G. Weston, Mr. A. Bullock, Mr. F. Bostock, Mr. W. H. Divers and Mr. A. N. Rawes, Secretary.

There were no new fruits or vegetables before this Committee, and other than that of judging the exhibits in the hall, it had no special business to conduct.

Groups.

Messrs. J. Cheal and Sons, Ltd., staged the only exhibit of fruits at this meeting. It comprised a grand collection of Apples, in splendid condition for so late in the season, the outstanding sorts being Encore, Crawley Beauty. Prince Albert, Ontario, Newton Wonder, King George V, Beauty of Stoke, Christmas Pearmain, Adams's Pearmain and Chelmsford Wonder; a very creditable display.

Salads, in excellent condition, were tastefully displayed by Messrs. Sutton and Sons. There were large baskets of Mustard, Cress and Corn Salad; grand Cucumbers of the variety Sutton's Improved Telegraph; the China Rose Winter Radish, and French Breakfast Radish; fine Cabbage Lettuces of the varieties Golden Ball and Sutton's Ideal; Witloof Chicory, Ivory White Seakale, salad Potatos, Water Cress, and grand Endive; a very instructive and excellently staged exhibit of splendid produce.

MANCHESTER AND SALFORD GARDENERS'.

The first Annual Meeting of this Guild was held at the Town Hall, Manchester, and was presided over by the Lord Mayor of Manchester. Colonel T. Westcott.

The Hon. Secretary, Mr. W. G. Ayres, reported that the Guild had only been in existence since June, 1927. Since then, plants and bulbs had been distributed to owners of small gardens and window boxes in the congested areas of both Manchester and Salford. The Parks Department of both cities had co-operated with the Guild by arranging to supply soil from the main parks and recreation grounds.

The Guild provided a panel of experts which worked in co-operation with the *Evening Chronicle* in the organisation of a Gardens Competition, and classes were provided in the competition for every kind of garden, including the more humble back-yard and window-box garden.

The Guild was already forming local branches upon many of the housing estates, and it was the hope of the Committee to form a branch upon every housing estate within its area. The business meeting was followed by an open meeting, at which Mr. W. W. Pettigrew, V.M.H., gave an address on "Town Gardening." A special plea was made to people occupying small houses to ornament them with window-boxes.

During the evening it was reported that one of the Manchester business houses had offered to present the Guild with two hundred window-boxes to distribute to tenants with no gardens.

READING GARDENERS'.

The fortnightly meeting was held in the Abbey Hall on March 18, when there was an excellent attendance presided over by the President, Mr. Frank E. Moring.

The lecture for the the evening was on "Strawberries," by Mr. M. Goddard, The Gardens, Bear Wood, who stated, in dealing with the cultural requirements of Strawberries, that it was more difficult to succeed in obtaining first-rate crops than it was a few years ago, and it makes one wonder whether there is such a thing as "reversion" in this plant. One of the principal points to success was certainly the preparation of the soil, and useful hints were given on this, as well as the various methods of layering the fresh runners, planting, the renovating of old beds, mulching, watering, and the picking and packing of the fruits. The lecturer then dealt with the forcing of Strawberries in pots, and practical suggestions were made as to the layering of runners for this purpose, potting on, temperature of the greenhouse, watering, etc. In conclusion, he recommended that, where greenhouses were not available, frames should be utilised, for by planting good strong layers in these during August, fruits would be ready for gathering a fortnight earlier than from plants in the open. Among the varieties recommended were King George, Royal Sovereign, Sir Joseph Paxton and Waterloo. A really splendid discussion followed. at the close of which a hearty vote of thanks was tendered to Mr. Goddard for his most valuable and practical lecture.

DERBYSHIRE HORTICULTURAL.

The Annual General Meeting of the Derbyshire Horticultural Association was held in the Guild Hall, Town Hall, Derby, on March 14, when substantial advancement in all branches was reported.

A new record was established by the enrolment of over two hundred new members during the past year, while the appreciation of the general public for the annual show was reflected in the attendance, which numerically exceeded anything recorded previously. Prize money was increased by almost £40, and the balance sheet showed an excess of income of £30 over the year's expenditure, with net assets £243 5s. 4d.

The Chairman, H. T. Ann, Esq., congratulated the members upon the successful season, and expressed appreciation of the help he had received from the Hon. Secretary, Mr. W. Wardman, and Mr. Smith, Vice-Chairman. Mr. G. Potter, the oldest member of the Association, was made a life member, he having been connected with the Chrysanthemum Show movement for forty-two years.

There were six vacancies on the Committee, the successful candidates being: Mr. J. Maxfield, Darley Abbey; Mr. L. Smith, Derby; Mr. A. H Harrison, Melbourne; Mr. J. McCartney, Kingston Hall; Mr. H. Wilson, Derby; and Mr. W. R. Powell, Newton Park.

The summer visits had proved very popular and thanks were tendered to Mrs. Walter Evans, of Darley Abbey; Dr. F. Milburn, of Kingston College; W. E. Ann, Esq., of Darley Fields; G. Gee, Esq., of Duffield Bank; The President, J. A. Aiton, Esq., of Duffield Park; Captain Drury Lowe, of Locko Park; and H. Woolman, Esq., for making the visits to their gardens so very enjoyable. The winter lectures have been well attended by members of both sexes, and the initial display by amateurs at the recently introduced monthly exhibition of fruits and flowers was very encouraging.

TRADE NOTE.

Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle*.

Obituary.

John Bannatyne, junr. — The death is announced of Mr. John Bannatyne, junr., a partner of the firm of Messrs. Bannatyne and Jackson, Nurserymen, Hamilton, which took place at his residence, Lansdowne, Hamilton, after a brief illness. Deceased, who was thirty-four years of age, was for many years Secretary and Treasurer of the Hamilton and District Gardeners and Forestry Association, and was widely known and respected in horticultural circles in the west of Scotland. The funeral took place on Wednesday, the 20th inst.

H. Silcock.—We regret to learn of the death, on Thursday, March 21, of Mr. Herbert Silcock, for twenty-two years gardener to Mrs. Anderson, Bassett Wood, Southampton. Mr. Silcock was ill but a few days, the primary cause of death being septicoemia following a dental abscess. He was sixty-two years of age. The funeral took place on Monday, March 25, and was attended by a large number of friends. The service was fully choral, Mr. Silcock having been a member of the church choir for many years. His sudden death is deeply regretted by his colleagues and all who knew him. He was greatly loved and a great gardener, with a wonderful knowledge of trees, shrubs and rock plants. He was always willing and anxious to impart his knowledge to all who wished for it. Mr. Silcock was one of the founders of the Southampton and District Gardeners' Society, nineteen years ago, and was a regular attendant at the meetings and shows.

Alfred Tomalin.—After only a week's illness the death occurred at 28, Heath Road, Crayford—where he had resided since his retirement—of Mr. Alfred Tomalin, for over fifty years gardener and estate manager to the White family at Oakwood, Crayford, Kent. He retired from active work about six years ago, when a brief sketch of his career was published in this journal. The funeral took place on Wednesday, March 20, at Crayford Parish Church, when the large attendance and the wealth of beautiful flowers bore witness to the high esteem in which Mr. Tomalin was held by all classes of the local community and of the horticultural profession, which he adorned for so many years. Mr. Tomalin leaves a widow, four daughters and four sons, who have received very many expressions of sympathy in their sorrow.

Ludwig Wittmack.—The German horticultural press reports the death, which took place on February 2, of the celebrated botanist Ludwig Wittmack, or, as he was affectionately called in his own circle, "Old Wittmack," an appellation not unmerited, as he had reached the advanced age of eighty-nine. Wittmack was born in Hamburg, and was at first intended for a pedagogic career, for which purpose he studied at Jena and in Berlin. He early specialised, however, in botany and agriculture, especially in the subject of agricultural seeds. As a professor in the Berlin Agricultural College, and instrumental in founding the Museum attached thereto, he had plenty of opportunities of indulging his botanical tastes, and was especially interested in Bromeliads, a subject which he studied for an article in Engler-Prantl's *Naturliche Pflanzenfamilien*. Two genera were named after him—Wittmackia, which is allied to Aechmea, and Wittmackanthus, a genus of the Order Rubiaceae. He made many interesting researches into prehistoric seeds, mainly founded on grave-discoveries. He was the author of many works, of which we may mention one on grass and Clover seeds published in 1873, which was re-published in a fuller form in 1922 under the title of *Landwirtschaftliche Samenkunde*. It is greatly to his credit that amid his multifarious occupations he gave much thought and attention to the subject of encouraging home gardening, the importance of which he was one of the first to recognise, at a time when his theories met with a good deal of raillery. Needless to say, his opinions have now received full recognition, and are shared by all in authority.

ANSWERS TO CORRESPONDENTS.

Allotment Land.—*W. H. P.* Under the Allotments Act, 1922, where land is let to any local authority for the purpose of being sub-let for use as an allotment garden the tenancy can be determined by the landlord by six months' or longer notice to quit, expiring on or before April 6, or on or after September 9 in any year.

Arums (Richardias) and Cyclamens infested.—*G. W.* The Arum (Richardia) foliage is insufficient material from which to make a diagnosis of the trouble. The rhizomes may be attacked by the soft-rot bacillus. One of the Arum leaves shows signs of damage by young slugs, the trouble resembling that found on Aspidistra foliage due to these pests. Search should be made after dark to ascertain whether freshly hatched slugs are present. The Cyclamen leaves are attacked by Begonia mite. Spray both surfaces of the foliage with Nicotine soap wash, this giving the best results. The plants may be dipped in sulphur soap wash, made by kneading a handful of flowers of sulphur with a six-inch potful of soft soap and dissolving it in about two gallons of water, keeping the material stirred throughout the operation.

Boiler for Heating a Greenhouse.—*G. H. J.* The heating of a greenhouse has to be reckoned according to the length of four-inch piping, and also upon the cubic capacity of the house A high house, or one that is exposed to the wind, is more difficult to keep warm than one that is low and sheltered. The part of Britain has also to be taken into consideration, although this can be calculated by the temperature experienced locally. Your district is a mild one. For instance, if the outside is at 40°F. and you wish to keep the temperature of the house at 45°F., eighteen feet of four-inch piping would be sufficient to warm 1,000 cubic feet. If the outside temperature were at 10°, that is at 22° of frost, you would require 126 feet of four-inch piping. The correct plan of heating is to have more piping than the minimum needed to give the required heat. When frost is experienced it then becomes a question of stoking without having to drive the boiler to excess. The Horse Shoe Boiler is a very efficient one for small greenhouses, and you could ask for the booklet L, from Messrs. Charles P. Kinnell and Co., Ltd., 65, Southwark Street, London, S.E.1. Measure the length of a flow and return pipe, each of which is the length of the house, and select a boiler that is capable of easily heating that length of piping.

Calcium Chlorate and Bishop's-weed.—*K. M. F.* If the above chemical substance ($CaClO_3$) will kill Field Bindweed, it would also kill Bishop's-weed, which never penetrates the soil so deeply. The Bishop's-weed should be allowed to start growing, when it will be much more sensitive to the chemical. It should be advanced enough sometime in May or early June, and that would give the chemical time to become decomposed before planting time in autumn. The calcium chlorate will be safe to use as it is not explosive like sodium chlorate and perchloric acid ($HClO_4$). Bishop's-weed in the grass plot may be got rid of by digging a trench at the edge of the grass and digging out all the roots. That in the grass may be killed by putting a good pinch of lawn sand in the crown of each plant, and repeating it every time the weed pushes up fresh crowns. The latter could also be spudded out with an old knife repeatedly to exhaust the roots. If you could arrange to have the turf lifted, the roots could be dug out and the turf relaid. This is the quickest way to get rid of it.

Names of Fruits.—*Suffolk.* 1, Hormead Pearmain; 2, Hollandbury; 3, Reinette du Canada; and 4, Rosemary Russet.

The Propagation of Hevea brasiliensis.

One of the many contributions that have been made by the Royal Botanic Gardens, Kew, to the economic development of the Empire was the introduction of Hevea brasiliensis into the East in the seventies of last century. The romance which attended the smuggling of seeds from the Amazon to Kew, the propagation of the tree there, and the transport of young plants to Ceylon, has often been told. But for many years thereafter Rubber planters did not recognise the need of further assistance from scientific institutions or men, and were content to propagate new stock from seeds collected at random in their plantations. The friends of the late Mr. W. Bateson will remember that, on his return from the meeting of the British Association in Australia in 1914, he strongly expressed his belief in the need for studying the "breeding" of Hevea; he was satisfied that true-breeding clones of differing yielding capacity existed, and that the average yield of plantations might be greatly increased by the application of plant-breeding methods. There may be no connection, but it is a curious fact that somewhere about 1915 the subject began to interest the Dutch research workers in Java. The first fact established was that the yield of Rubber from individual trees varies from 3 lb. to 40 lb. per annum, and that thirty per cent. of the yield of any plantation may be dependent on the yield of less than ten per cent. of the trees. It was next established that the yield of trees propagated from the seeds of a heavy yielder is sensibly higher than that of the average tree. Now Hevea brasiliensis is normally cross-fertilised, and self-fertilisation is rare and impossible to achieve practically. So that here we have the same difficulty as that upon which we recently commented in relation to the Cabbage family (p. 111), for the trees are predominantly heterozygous and do not breed true. Lately, a further advance has been made ; for if vegetative propagation of a hybrid plant can be practised, no genetic complication need arise. Experiments on the budding of Hevea have now been going on for some years, and are already giving definite results. Once the high-yielders had been identified by keeping records of the yields of individual trees it became a comparatively simple matter to multiply trees of the same character by budding, although, as might have been expected, some problems relating to the action of stock on scion still remain to be solved. Already, in Java and Sumatra, results from budded trees are so remarkable that the systematic replacement of the existing stocks in plantations by budded high-yielders is likely to become universal. The botanical puzzle—what, if any, is the survival value of latex to the species that secrete it ?—still remains unsolved, but a recent discovery seems to support the view that it is purely a waste product, playing no part in the nutrition of the tree, and generally unaffected by environmental conditions. In a paper recently read to the Rubber Research Association, a member of the staff, Mr. Herbert Ashplant, announced that he had proved there is a high correlation between the yield of Rubber, and the average diameter of the laticiferous "tubes" which carry it just below the bark ; this diameter, moreover, is a genetic characteristic of the tree, measurable even in the petioles of seedling leaves. It would seem to follow, therefore, that the secretion of latex is controlled by the storage capacity ready to receive it, rather than by any nutritive demand. Incidentally, the discovery furnishes a means of rogueing seedling nurseries, for under existing methods the value of the tree cannot be determined until the tapping age (at least three years) has been reached, whereas by Mr. Ashplant's method the high-yielders can be picked out after one year's growth. Returning to budding, it may be mentioned that an interesting monograph* on the subject was recently issued by the Rubber Research Institute of Malaya. The author, Mr. F. Summers, describes the progress already made by the Dutch and Americans in Java and Sumatra, and the lamentably late development of budding in British possessions. It is little wonder, therefore, that Mr. Ormsby-Gore, in his recently published report on a tour in the East, should devote a considerable section to proclaiming the success of the Java work. Writing of the slowness with which Rubber research has progressed in British dependencies, he makes the caustic comment : "Unfortunately, the planters, or the employers in London who control them, are not always as familiar as they might be with the scientific material for forming a considered judgment." Mr. Summers' monograph, however, shows that this reproach is no longer justifiable, and that the workers in Malaya are actively engaged in making good the ten years' leeway behind the Dutch and American workers in Java and Sumatra.

Our Coloured Supplement Plate.—The Coloured Plate, presented as a Supplement to this issue, is of the beautiful New Zealand Kowhai, Sophora tetraptera, a shrub, or, as in its native habitat, a tree of from fifteen feet to forty feet high. Belonging to the Natural Order Leguminosae, it is an extremely handsome subject, its downy, zigzagged branches being furnished with pinnate leaves up to five inches long, and bearing a profusion of racemes of beautiful Pea-shaped flowers. S. tetraptera is not so hardy as to pass through the winter unscathed in the colder parts of this country, even although afforded the protection of a wall, but for the milder districts, or for specially sheltered positions, it is a worthy claimant for a place. It thrives in a rooting medium of sandy loam and is very quick-growing in the early stages, being easily raised from seeds.

The New Curator of Kew.—Mr. T. W. Taylor, the Assistant Curator in charge of the Tropical Department, has been appointed to succeed Mr. W. J. Bean as Curator of the Royal Botanic Gardens, Kew.

Royal Horticultural Society's April Exhibitions.—As already stated in these columns (p. 236), the Daffodil Show, which was to have been held in the Society's new hall in Greycoat Street, Westminster, on April 9 and 10, has been postponed for a week. It will now be held in the old hall in Vincent Square, Westminster, on Tuesday and Wednesday, April 16 and 17. All entries must reach the Secretary not later than by the first post on Saturday, April 13, but it will be helpful if they arrive earlier. In view of the postponement of the Daffodil Show, the Society will hold an ordinary fortnightly show in the new hall in Greycoat Street, Westminster, on Tuesday and Wednesday, April 9 and 10. The Fruit and Vegetable, Floral, Orchid, Narcissus, Scientific and Library Committees will meet at the usual times on Tuesday, April 9, but as the Daffodil Show is confined to Daffodils, only the Narcissus Committee will meet on Tuesday, April 16.

Rotterdam Spring Show.—In consequence of the long period of very hard frost which occurred during February, Dutch growers have suffered very severely, their crops being much later than usual, and it has been found necessary to postpone the projected Spring Exhibition in Rotterdam to a considerably later date than was at first contemplated. The dates have now been fixed for April 24 to 28, and it is hoped that by this means the exhibition may be made a complete success, and once more demonstrate the high standard attained by the Dutch horticulturists.

Lauriston Castle, Edinburgh.—An important addition to the list of public parks in Edinburgh is to be made during the summer, when the historic Lauriston Castle will be handed over to the Edinburgh Corporation under the will of the late Mr. and Mrs. W. R. Reid.

Grant for the Development of the Potash Industry in the United States.—The Congress of the United States of America has recently authorised the appropriation of a sum not exceeding $50,000 for the fiscal year ending June 30, 1929, and a similar sum for each of the three succeeding fiscal years, the money to be expended jointly by the Departments of Agriculture and Commerce in the investigation and development of improved and cheaper methods for recovering potash from the various potash-bearing deposits in the United States.

The Playing Fields Movement.—In a letter to the Press, on behalf of the National Playing Fields Movement, Sir Arthur Crosfield (Chairman of the Council), General Lord Cavan (Chairman of the Appeal Committee), and Mr. Noel Curtis-Bennett (Hon. Treasurer), give the following facts demonstrating the results, both direct and indirect, following the appeal made by the Duke of York in June, 1927, on behalf of the movement :—(1) Five hundred-and-thirty-five acres of land, to the value of £138,000, have been given to the Association or to local authorities in response to the the appeal, and further gifts of this kind are still being received. (2) Contributions of over £164,000 have been made to the

* "The Budding of Hevea in Modern Plantation Practice," by F. Summers ; *Rubber Research Institute of Malaya Planting Manual.*

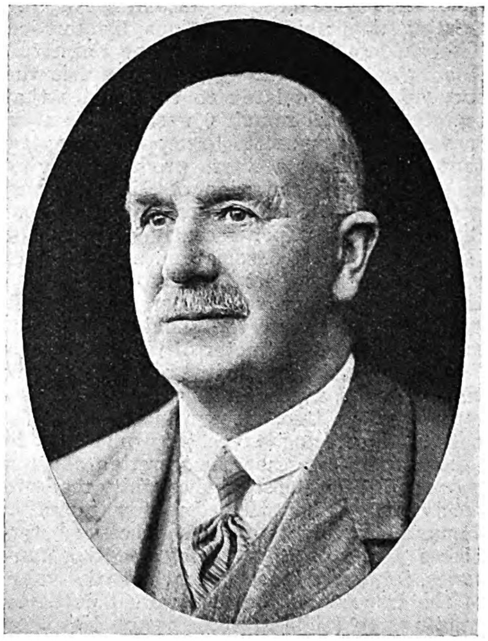
Association and its branches. (3) The Carnegie Trustees have set aside the magnificent gift of £200,000, to be used for the purchase or laying-out of recreation grounds. (4) Three-hundred-and-seven schemes for purchasing or laying-out playing fields have been initiated by local authorities or committees during the last eighteen months and referred to the Association for advice and financial support. These schemes extend to a total area of 3,806 acres, and involve an outlay of £1,130,674. "It can therefore be said," they announce, "that since the national appeal was launched, facilities for public recreation have been or are being provided at a cost of £1,632,674, apart from many important schemes carried through by local authorities without aid from the Association and the Carnegie Trustees. These results are very encouraging and show that a really satisfactory advance has been made in many districts: elsewhere, unemployment and high rates have rendered it impracticable for schemes to be undertaken for the purchase of playing fields, even where the need is most acute. The evidence of the serious shortage of recreation grounds is indeed overwhelming, and the Association can only hope to achieve its aims if it receives the continued and extended interest and financial support of the people of this country."

Land Surveying by the Romans.—The re-arrangement of the various collections in the galleries of the Science Museum at South Kensington, has resulted in the introduction of an exhibit illustrating surveying. In this, the work of the Roman land surveyors comprises a very interesting group, and includes a reconstruction of an ancient Groma, two Roman measuring rods, and a map prepared by Sir Montague Sharpe showing the boundaries laid in Middlesex by surveyors during the Roman occupation of Britain.

Tewkesbury Daffodil Show.—Owing to the lateness of the season, the Annual Show of the Tewkesbury and District Daffodil and Spring Flower Society, which was to have taken place on April 11, has been postponed to Friday, April 19. Entries close with the first post, Monday, April 15.

The Easter Holidays.—Fine weather once again favoured the British Isles for the Easter Festival, so that the millions of holiday-makers were able to enjoy to the full the respite from their labours, and although Easter Monday—as though the clerk of the weather was fearful of overstepping the bounds of generosity—was more typical of early April and not so warm and summer-like as the three preceding days, yet the weather was not sufficiently doubtful to mar outdoor pastimes. This was evidenced by the general exodus of Londoners, as well as of occupants of other big cities, to the country and seaside resorts, the many favourite spots on the outskirts of London—Epping Forest, Hampton Court, Kew, Windsor and Epsom Downs being particularly popular. And those who were unable to leave London sought consolation, and found it, in the many beautiful public parks and gardens, and were able to enjoy to the full the brave displays of early spring flowers. Likewise their "country cousins" arrived in their thousands and took possession of the museums, the Zoological Gardens, etc. And yet the aftermath of the Easter Festival was not so bright and pleasing, for still we learn of inconsequent littering of the countryside and, what is worse, the disfigurement of many acres of beautiful grassland, heathland and woodland by fire, and this despite the combined efforts of the press and local authorities in warning the public against actions which lead to damage. A lighted match or cigarette-end is presumed to have been the cause of a serious fire which occurred on Budley Common, near Edwinstone, and which at one time threatened to envelop Sherwood Forest. The sorry tale of the disfigurement of the Home Counties by fire includes:—140 acres of Witley Common, Surrey; a large fire on Epsom Common; thirty acres of woodland on the Marshalswick Estate, St. Albans; a big plantation at Nonsuch Park, Cuddington; a large area of Gorse-land on Harpenden Common; fifty acres of grass-land between Chesham, Buckinghamshire, and Lye Green; a big patch of grass-land on Wimbledon Common, and a host of others. A devastating fire broke out at Bordon, in Hampshire, on Bank Holiday evening, and raged throughout the night and the greater part of Tuesday, and before being brought under control by the troops from Bordon and Longmoor camps, laid waste to a great area of Heather and Fir trees. On Tuesday, also, extensive damage was caused by Gorse fires in Monmouthshire, while two Gorse fires of considerable extent occurred at Epping Forest.

Mr. Alexander C. Davidson.—Fifty years' service in one place is a fine record, and this record has been achieved by Mr. Alexander Craig Davidson, Superintendent of Parks for the Borough of Gateshead. This jubilee of service was celebrated on March 23, when Mr. Davidson was presented with a suitably engraved gold watch by the members of his staff, while Mrs. Davidson received a gold wristlet watch as a memento of the event. When nineteen years of age, Mr. Davidson came from Bothal, Northumberland, to become a journeyman gardener at Saltwell Park, Gateshead; at this time the staff consisted of nine persons and the park of thirty acres was very like the private garden it had been for many previous years. Five years later he became foreman, and seven years afterwards Superintendent, a post he has held for thirty-eight years to the great satisfaction of the townsfolk of Gateshead. There have been additions during Mr. Davidson's regime, including The Grove, which may be closed for band performances, concerts, etc., the charge for admission contributing handsomely towards the cost of the upkeep of the parks. Saltwell Park is finely planned, and the arrangement of bowling greens and tennis courts is evidence of Mr. Davidson's skill as an organiser, as the arrangements permit of great economy in oversight and upkeep. The Terrace, with its fine views, the summer bedding, the lake, and the Maze, are all popular features of Saltwell Park, where now the staff numbers thirty-five.



MR. ALEXANDER C. DAVIDSON.

Trees of Remembrance.—The Roads of Remembrance Committee of the Roads Beautifying Association is appealing to the public to co-operate with it in planting trees in commemoration of those who fell in the Great War, or died at other times; of any outstanding event in public or private life; of the visit of any prominent person to this country; of occasions of national rejoicing or mourning; and of births, marriages or deaths. By the kindness of the Surrey County Council, with whom the Roads Beautifying Association is collaborating in roadside planting, certain trees can be allotted on the Kingston By-Pass for Remembrance purposes, according to the wishes of the donor. Should members of the public wish to plant trees on any other road than that mentioned, if such roads are suitable for this purpose, *i.e.*, having a sufficiently wide margin at the side, the Roads Beautifying Association will approach the highway authorities concerned, and request permission for the planting of such trees. The Roads of Remembrance Committee will make arrangements for the preparation of the ground, the provision, planting and staking of such trees, together with the fixing of a permanent tablet, for the inclusive sum of two guineas per tree. A list of trees suitable for wayside planting is appended to the published appeal.

Frost Damage to Horticultural Crops.—The recently issued *Report* of the Ministry of Agriculture on the condition of horticultural crops shows widespread damage from the severe weather of February and early March. Autumn sown Beans and Peas are badly affected everywhere. Excellent Broccoli are reported from Cornwall, but elsewhere much damage was done and prospects are poor; autumn-planted Cabbages in general have suffered severely and the crops will be very late. Lettuces out-of-doors have been damaged severely generally, in some places only a small percentage of the crop having survived; Rhubarb, Seakale, and spring Onions in the open were checked, and these crops will be much later than usual.

Power Machinery for Orchard Cultivation.—The Middlesex Agricultural Education Committee, in co-operation with the Ministry of Agriculture, is organising a demonstration of power-driven implements suitable for orchard cultivation. The range of implements will be representative. The demonstration will be open to the public, and will be held, by courtesy of Mr. Whittingdon, at Perry Oak Farm, Heathrow, Hounslow, on Wednesday, the 10th, and Thursday, the 11th inst., from 11 a.m. to 4 p.m. each day. Those engaged in fruit cultivation on a commercial scale should find the demonstration of considerable interest.

Destructive Woodland Fires in Scotland.—Two very destructive woodland fires occurred in the north of Scotland during the past week-end. The famous Binn Hill, Huntly, Aberdeenshire, for generations the property of the Dukes of Richmond and Gordon until disposed of some years ago, was the scene of a violent outbreak when over three hundred acres of young trees were destroyed. The Forestry Commission has been hard at work on the hill every planting season since, and including, 1926, and fine results were being achieved. The damage is estimated at over £2,000. How the fire originated has not yet been determined. The second outbreak was on the estate of Edderton, near Tain, Ross and Cromarty. Getting out of control, and aided by a strong wind, the fire assumed alarming proportions, and quickly spread to the adjoining estates of Rosehill, Quarry Hill, Ardlarach and Tarlogie, where there are considerable acreages under young trees. Colonel Ritchie of Ardlarach was quickly on the scene and organised a vigorous campaign to prevent the fire spreading. The result was eminently successful, many young plantations and the fine avenue leading to Ardlarach House being saved. Nevertheless, much serious damage was done, especially on the estates of Rosehill and Ardlarach. The conflagration was brought about by Heather burning, by which so many serious fires have their origin.

Hélène Costantin and her Art.—Accompanying a kindly letter, Professor Georges Jamin (Professor Hon. de l'Ecole Lavoisier, Paris), sends the following note:—"In one of the chapters of the *Forsyte Saga*, Galsworthy depicts for us a water-colour artist who seeks his inspiration in the Botanical Gardens. One day, when I was admiring, at the Salon de l'Eclectique, in Paris, the Oaks, Pines and Beeches painted by Mdlle. Hélène Costantin, I thought of the young Jolyon Forsyte. Like him, indeed, Hélène Costantin has acquired a taste for nature in the midst of the trees of the town. Her father is the well-known Professor of Botany at the Natural History Museum. For seventeen years she lived at the Jardin des Plantes, in Paris, and there formed her taste for the arts, and was enthused with a desire to reproduce the forms of those plants and trees whose mysterious life and the artistic and moral lessons they teach, had been explained to her by her father. But Hélène Costantin does not transmit her impressions by water-colours or in oil; she uses wool and canvas, and the decorative effect of her tapestry is quite striking. Those who have seen her landscapes of Brittany or the Ile de France, at the Salon des Artistes Français and the Salon d'Automne, cannot have failed to admire them. The art critic who did not mention so original and personal a method would be false to his duty, which undoubtedly is to bring to public notice those artists who, avoiding the beaten path, display to us a fresh aspect of nature, always infinite in variety and eternal in beauty."

Export of British Potatos to Germany.—The Ministry of Agriculture announces that arrangements have now been made, through the Foreign Office, under which Potatos of United Kingdom origin gathered before December 1 last may be imported into Germany on payment of the reduced duty of one Reichmark per one hundred kilogs. The condition attached to this arrangement is that a statement to the effect that the Potatos were gathered before December 1 last must be endorsed on the certificate issued by officers of the appropriate Departments of Agriculture to meet the requirements of the German regulations regarding the prevention of the introduction of Potato blight. The statements should be in both German and English.

Kirstenbosch Botanic Gardens.—The National Botanic Gardens at Kirstenbosch, near Cape Town, were established in 1913, and form part of the Groote Schuur Estate bequeathed to the South African nation by Cecil Rhodes. In 1922, a further site, known as the Upper Kirstenbosch Nature Reserve, Table Mountain, was placed under the control of the Botanic Garden authorities, for the better protection of the native vegetation. The latest *Report*, issued at the end of 1928, states that steady progress in the establishment of the various plant collections has been made, and an average of about nine contributions of seeds and plants reaches the Gardens daily. An important piece of recent development is a new Succulent Garden, the need for which has been acute ever since the early days of the Gardens. The provision of a Succulent house has made it possible to accommodate the smaller Succulents—Lithops, Conophytum, Anacampseros, etc.—while the garden will form a permanent home for the larger species. The site was chosen in 1922, but lack of funds made further progress impossible until 1927. A special expedition for the collection of material was made to the South West African Protectorate in August-September, 1927, and resulted in large collections of valuable material. The Kirstenbosch Botanic Gardens are open to the public during daylight every day of the year, without charge for admission, and many thousands of visitors take advantage of this privilege.

Haarlem Daffodil Show Postponed.—Owing to the lateness of the season the Daffodil show arranged to be held by the General Dutch Bulb Growers' Society, at Haarlem (Holland), has been postponed to April 25 and 26. Intending exhibitors must give notice to the Secretary, Mr. H. J. Voors, Krelagehuis, Haarlem, not later than April 18.

Chinese Primulas.—On March 26, on the invitation of the Council of the Royal Horticultural Society, Professor W. Wright Smith, Director of the Royal Botanic Garden, Edinburgh, delivered a lecture on "Chinese Primulas" before the Fellows of the Society, in the lecture room of the new hall. The lecture was based on the revision of the genus Primula by Professor Smith and Mr. George Forrest which was prepared for the R.H.S. Primula Conference at Chelsea last year, and was reprinted in the recently issued volume of the R.H.S. *Journal.* The lecture was illustrated by a series of lantern slides of Primroses, prepared from photographs of species in the field, taken by Mr. Forrest and Dr. Handel-Mazzetti, or of plants growing at the Edinburgh Botanic Garden or at Wisley. One or two coloured slides of Primroses growing on the mountains of western China were of unusual interest to cultivators of exotic Primroses, and the whole series was illustrative of the perfection to which plant photography can be brought. The slides were thrown on the screen with excellent effect by a new lantern which, it is understood, was on trial for the occasion. It was in welcome contrast to the old lantern with which both Fellows and those who have been invited to lecture in the old hall are all too familiar.

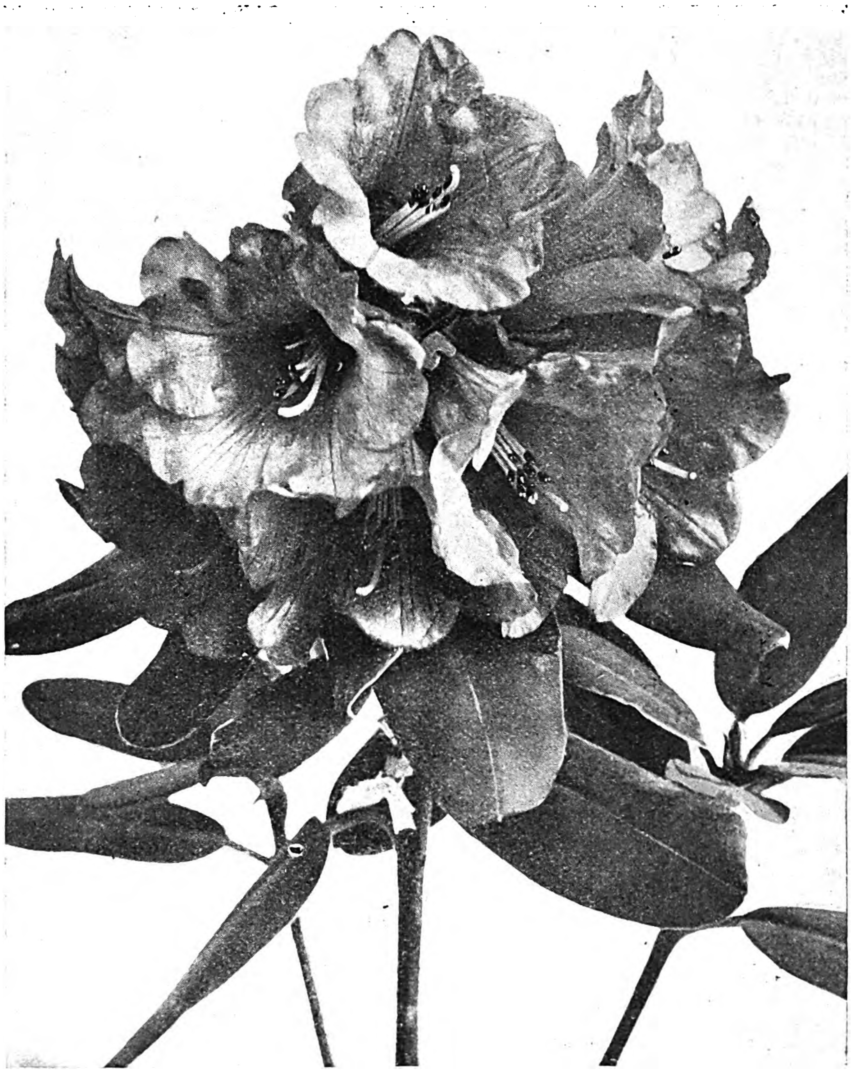


FIG. 130.—RHODODENDRON EUCHAITES.

R.H.S. Award of Merit, March 26. Corolla and calyx red. Shown by Lady Aberconway and the Hon. H. D. McLaren (gr. Mr. F. C. Puddle), Bodnant (see p. 252).

Appointments for the Ensuing Week.—Monday, April 8: Harrogate and District Horticultural Association's meeting. Tuesday, April 9: Royal Horticultural Society's Committees meet; two days; in the new hall (see p. 255); Jersey Gardeners' Society's meeting. Wednesday, April 10: Brighton, Hove and Sussex Horticultural Society's Show (two days); Falmouth Spring Flower Show (two days); Sheffield Chrysanthemum Society's lecture; Brussels Commercial and International Fair (fourteen days April 10 to 24). Friday, April 12: Faversham Chrysanthemum Society's meeting; Royal Horticultural and Arboricultural Society of Ireland's meeting; Huntingdonshire Daffodil Society's exhibition.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Rhododendron Dalhousianum.*—At the meeting of the Horticultural Society held on April 4, the Right Hon. Lawrence Sulivan in the Chair, by far the most novel and striking object exhibited on this occasion was a flowering specimen of Rhododendron Dalhousianum, from Mr. Packman, gr. to J. Gadesden, Esq., of Ewell, to whom belongs the honour of having been the first to flower this plant in England. The only other place in which it has yet blossomed in Britain is Dysart House, in Fifeshire, where it produced flowers last year, under the care of Mr. Laing, gr. to the Earl of Rosslyn. Mr. Gadesden's plant had had five blooms on it; but two of them had dropped, leaving, of course, only three behind, each of which measured about 4½ inches in diameter, and as much in length. They somewhat resembled the flowers of the white Lily (L. candidum), except that they were tinged in the throat with yellow. Notwithstanding their great size, they were not at all flimsy in texture; on the contrary, the petals were thick, and the flowers extremely well-formed. When it is considered that a single stem, some 18 inches in height, produced five flowers, the display that may be expected to be made by a large specimen, covered with blossoms of the dimensions stated, must be grand indeed; and, therefore, whether this Rhododendron prove hardy or not, it must certainly be regarded as a great acquisition. A Knightian Medal was awarded it.—*Gard. Chron. April* 8, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

The Cool House.—Many plants in this house are now developing flower spikes, notably Odontoglossums in variety, together with the bigeneric hybrids, Odontiodas, Oncidiodas, and others, and these form a remarkably free-flowering group of cool house Orchids, their graceful spikes of beautifully coloured flowers being very decorative, either on the plant or when cut. Where large quantities are grown, some plants may be had in flower practically the whole year round. If slugs are troublesome, stand the plants now developing spikes over water, or wrap cotton-wool around the base of the spike; this should be renewed frequently. Lettuce leaves and small quantities of bran should be placed about the staging as traps, and should be examined at night, when the slugs are usually feeding. The young flower spike should be secured loosely to a neat stake in the early stages to enable the flowers to be displayed in a graceful manner. At this stage of growth ample supplies of water will be required at the roots each time the compost appears dry. Measures should be taken to keep thrips in check; these are often found around the buds, therefore, when the plants are sprayed with an approved insecticide at fortnightly intervals, the flower spikes should be sprayed thoroughly too, until the buds are about to expand. Plants that flowered during the autumn and early winter months, and now require repotting, may be attended to. The best stage at which Odontoglossums and allied kinds may be repotted is when the young growths are well advanced and just beginning to swell, as more new roots are generally produced then than in the early stage. Use well-drained pots and a soft, open compost of equal parts of Osmunda and soft A.1. fibre, and one part Sphagnum-moss; a little extra moss may be used for finishing off the surface. When repotting, decayed pseudo-bulbs and roots should be cut away; retain three pseudo-bulbs to each lead. Some varieties are susceptible to rhizome rot, and if this is detected all affected portions should be cut away and destroyed, the sound piece being allowed to dry before being potted up; it is advisable to dust any severed part of the rhizome with powdered charcoal. Over-potting should be avoided, and the base of the plant should be kept level with the pot rim, and just in contact with the compost, which should be pressed firmly among the roots, but should not be built up around the pseudo-bulbs or young growths.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Raspberries and Loganberries.—These suffered during the recent severe weather, but not badly. Shorten any canes that the frost may have injured to a plump bud, and see that all the ties are secure. Where a new plantation has been made the canes should be cut down almost to the soil level. Give a further firming of the ground about them by treading, but take care not to damage the young basal growths which are now appearing. Raspberries thrive best when afforded a deep, cool and moist root run. The plants will therefore benefit greatly by a good mulching of half-decayed manure applied now and spread evenly on both sides of the rows to the outward extent of about eighteen inches. Neglect in this matter may result in the fruits becoming hard and undersized in the event of a dry spell of weather during the ripening season. Where it is desired to increase a particular Raspberry stock, preserve all the young suckers that appear just now, and when they attain the height of six inches or so, carefully lift them with a trowel and plant them eighteen inches apart in permanent rows. By following out this method, a whole year is saved. The young plants become established immediately.

Big Bud Mite of Black Currants.—The tar-distillate wash applied in February should now be followed by a lime-sulphur spray at a strength of one in twelve, for the destruction of the migrating mites. The most effective period for this application is when, on healthy growths, the flower trusses appear outside the buds, but the flowers have not actually opened. The aim should be to defer the operation until the last moment, and where possible to treat each variety according to its period of flowering; by that, I mean to take the condition of the flower racemes as an indication of the proper time. Black Currant varieties vary, like other plants, in their time of coming into leaf and flower. Thus, the variety Baldwin is very early, and Goliath late, in coming into bloom. It is obvious then that we would not obtain the best results if these two varieties were sprayed on the same date. Slight scorching of the young leaves is almost certain, but the bushes seem to suffer no ultimate damage. The weather at the time of applying these sprays is an important factor towards success or otherwise in obtaining a control. I do not know of any statistics with regard to rain following on spraying, but, if the spray has had time to dry on the bushes, only very heavy rains will appreciably reduce the spray's effectiveness.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Peaches.—The earliest Peaches and Nectarines will now be stoning, if they have not already passed this trying ordeal, and the fruits, to outward appearances, will be making little progress. It is impossible to state how many Peaches a pot tree will ripen to full average size, but of two evils it is better to crop the trees moderately, if fine fruits and good wood are to be secured, rather than to handicap the trees by endeavouring to overcrop them. Disbudding and thinning should now be almost completed, but care should be taken that the shoots do not crowd each other. Vigorous trees will require constant attention to pinching of shoots and laterals, commencing at the top of the tree and working downwards gradually, the first factor being the maintenance of perfect pyramids and bushes well set with triple buds for another year. Heavily cropped trees will not require this incessant attention, for medium growths on such trees will not make more than two wood buds; to strengthen these, any growth inclined to take an undue share of the sap must be pinched when about ten inches in length, and any subsequent laterals and sub-laterals at the first or second leaf. Top-dressings should be applied as often as the roots appear on the surface until the Peaches are nearly ripe. Whatever is used should be given little and often, and an abundance of water should be afforded, as dryness at the roots is fatal to all fruit trees. Pure, soft water is best for syringing them, as it does not leave a deposit on the fruits. Occasional applications of soot-water are also beneficial. The temperature, after the fruits have stoned, may be raised to 60° or 63° at night and 70° to 75° by day, allowing a rise to 80° through sun-heat after closing.

Peaches in Cold Houses.—These are later than usual. All watering or damping down should be done in the morning, but the less water applied the better, as flowering trees in a dry atmosphere will withstand frosts better than if the atmosphere is moist. Any weak trees may have the badly placed and weakest flower buds removed, with the result that those left will be strengthened. Trees in unheated houses should have abundance of air throughout the day, and also at night, when freedom from frost is certain. Disbudding of crowded shoots should not be delayed long enough to rob the shoots intended to remain. When the days lengthen and the nights become milder, the syringe should be brought into greater use. Thinning should begin early on healthy trees that are well nourished at the roots, as these seldom cast their fruits at stoning time.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Pruning Roses.—In the south of England, the end of March is a suitable time to commence the pruning of Roses, but so much depends on the season that no definite date can be fixed for this annual operation; it is better to err on the safe side and be a week later, than run the risk of the tender young growths being damaged by late spring frosts, which tends to weaken the plants and make them more susceptible to attacks of aphis, mildew, etc. The laying down of hard and fast rules for pruning Roses is well nigh impossible; many growers seem to think that all growths of Rose bushes must be cut back to three or four buds. This, of course, is wrong; the plants ought to be treated according to the section to which they belong, with due regard to whether they are weak or strong growers. Those having Pernetiana blood, and the majority of the Teas, give the best results if only pruned lightly. The removal of weak and worn-out growths is all that is required if sufficient space is available for their development. Under such treatment these Roses flower more freely and continue in bloom longer than when cut hard back in the usual way. Such a method does not appeal to those who must have all their plants about the same size and shape, but will give pleasure and joy to the Rose lover. Begin by pruning the hardiest varieties, such as the Hybrid Perpetual and Hybrid Tea sorts, leaving the more tender Teas until the last. Remove all weak shoots to commence with, pruning the remainder back to the number of eyes required; cut obliquely just above a bud pointing outwards, unless the variety being dealt with is of a sprawling habit, then prune to a bud pointing inward, to encourage the formation of a shapely bush. Vigorous-growing kinds, such as Hugh Dickson and Frau Karl Druschki, give the best results if the long growths are pegged down instead of being cut back. Single Roses should be pruned sparingly, removing only the weak growths and allowing the others to remain at full length.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Begonia Gloire de Lorraine.—Plants of this Begonia that were cut down, as advised previously, should by now have developed good strong basal shoots, which undoubtedly give the best results as cuttings; and if these are not sufficiently advanced it will be wise to allow them to grow longer rather than to use weak top-growths as cuttings. This Begonia may also be increased by means of leaf-cuttings, but if suitable cuttings are forthcoming I see no need to trouble about raising plants by these means. The cuttings, when available, should be severed with a sharp knife and inserted several together in a small pot containing a mixture of loam, leaf-mould and a little peat, with sufficient sand and broken charcoal added to keep the compost open. The cuttings should be stood in a propagating frame on a mild bed of leaves, and a temperature of from 65° to 70° maintained. If eelworm has been troublesome it will be wise to sterilise the soil. Begonia mite must be kept in check by spraying with a Nicotine wash or, in the early stages, by the use of the sulphur vapouriser.

Winter Pelargoniums.—Cuttings of Zonal Pelargoniums for winter-flowering should be obtained with as little delay as possible. These may be inserted singly in small pots or several may be placed around the sides of a larger receptacle. The cuttings should be inserted and made firm, and the pots placed on a shelf in gentle warmth, but free from excessive moisture. Failing this, they should be placed in the warmest part of the house and kept somewhat on the dry side until roots are formed. To obtain good specimens the plants will need pinching several times during the summer; for forming extra large specimens, some of the old plants should be retained, cut back, and encouraged to break into growth, after which they should be potted on into larger receptacles. During the summer, keep all flower-buds removed and the growths pinched back to ensure bushy growth.

Winter-flowering Begonias.—Begonias of the Mrs. Heal, Optima and Exquisite type should now be encouraged to produce good, strong shoots for propagating purposes. These Begonias have passed through the winter splendidly, no doubt owing to the drier atmosphere and fewer fogs experienced than usual. The old stools may now be removed from their receptacles and, after carefully reducing the ball of soil, should be repotted into smaller pots, using a rich, open compost. After potting, careful watering is needed until growth is active again. Syringe frequently between the pots, but I do not recommend spraying the plants overhead at any time. These Begonias are often troubled with mite and rust during their growing season, but these may be kept in check by occasionally fumigating the house with sulphur vapour. Mite alone can be kept in check by spraying with a Nicotine wash. It is advisable to fumigate the plants as advised immediately they show signs of active growth, especially where mite was troublesome last year. This group of Begonias will repay extra care in cultivation, for they are delightful subjects for flowering during the dull months of the year.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Celery.—Trenches may now be prepared for the early plants, choosing a time when the ground is not too dry for making them. Single or double, or even four lines, of Celery may be grown in a trench, the bottom of which should be deeply forked and well enriched with decayed farmyard manure.

Maize.—Seeds of Maize may now be sown in four-inch pots, one seed in a pot, and germinated in moderate heat. The seedlings should be hardened off gradually in a cool frame, after which, when the likelihood of frost is past, they should be planted out in ground which receives plenty of sunshine, and which has been well enriched with manure.

French Beans.—To provide a succession, another batch of French Bean seeds may be sown in frames. Sutton's Pioneer is equally valuable for frame or pot culture, or for growing in the open; it is first-rate in quality, a good cropper, and quick-growing.

Hoeing.—When the various seedlings are through the ground, no time should be lost in loosening the soil between the rows with the Dutch hoe. This will hasten their growth and also keep weeds in check. The use of the Dutch hoe is a great factor in securing strong, healthy plants, and it should be employed with unfailing regularity.

Seakale.—The thongs that were prepared as cuttings when the Seakale crowns were lifted, and which have been kept in ashes, may now be planted in ground that has been deeply dug and well manured. Plant them ten inches apart in rows twenty inches apart; when planted, the tops of the thongs should be just beneath the surface of the soil.

Leeks.—If Leeks are still in the ground they should be lifted and laid in a trench in a shaded position. This will retard their growth and make them last longer, whereas, if left in the bed, they will soon run to seed.

Seed Sowing.—Continue to sow batches of Peas, Radish, Mustard and Cress, Spinach, Turnip and Lettuce for succession.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemount, Monkton, Ayrshire.

Broccoli.—Where this crop has wintered successfully it should be assisted by surface cultivation and a dressing of sulphate of ammonia.

Asparagus.—The established Asparagus beds may now receive attention. The manure used as a mulch may be "pointed" into the surface soil between the plants, together with a liberal dressing of coarse sand and burnt earth if the soil is of a heavy nature; a digging fork is best for this operation if the roots or crowns are near the surface. The alleys between the beds should receive the same treatment. A good dressing of salt is of great benefit to this crop, and when growth is a little further advanced, a few very light dressings of sulphate of ammonia at intervals of ten days or so will hasten the production of the crop. Where difficulty is experienced in growing this valuable vegetable, do not give up hope until sowing the seeds in the permanent beds has been tried. Prepare the ground as for planting by working it very deeply and incorporating plenty of manure. On such a prepared site the seeds may be sown now, in rows eighteen inches apart. The beds should each consist of three rows, an alley about three-and-a-half feet wide being left between each. When the seedlings appear, thin them gradually until they are at least twelve inches apart, and encourage growth by surface cultivation with the Dutch hoe. Support the growths with small twigs during the first year, after which the procedure is as for established beds, but cutting should not commence until the third year.

Early Potatos.—A rather larger batch of tubers of early Potatos should be planted in the most favourable position possible. If the soil is of a retentive nature do not plant them too deeply, and allow a few inches more between the rows to allow soil for earthing up. If well sprouted, the sets should be laid on their sides to avoid breaking the growths and also to delay their appearing through the ground, so that they will not be damaged by late frosts.

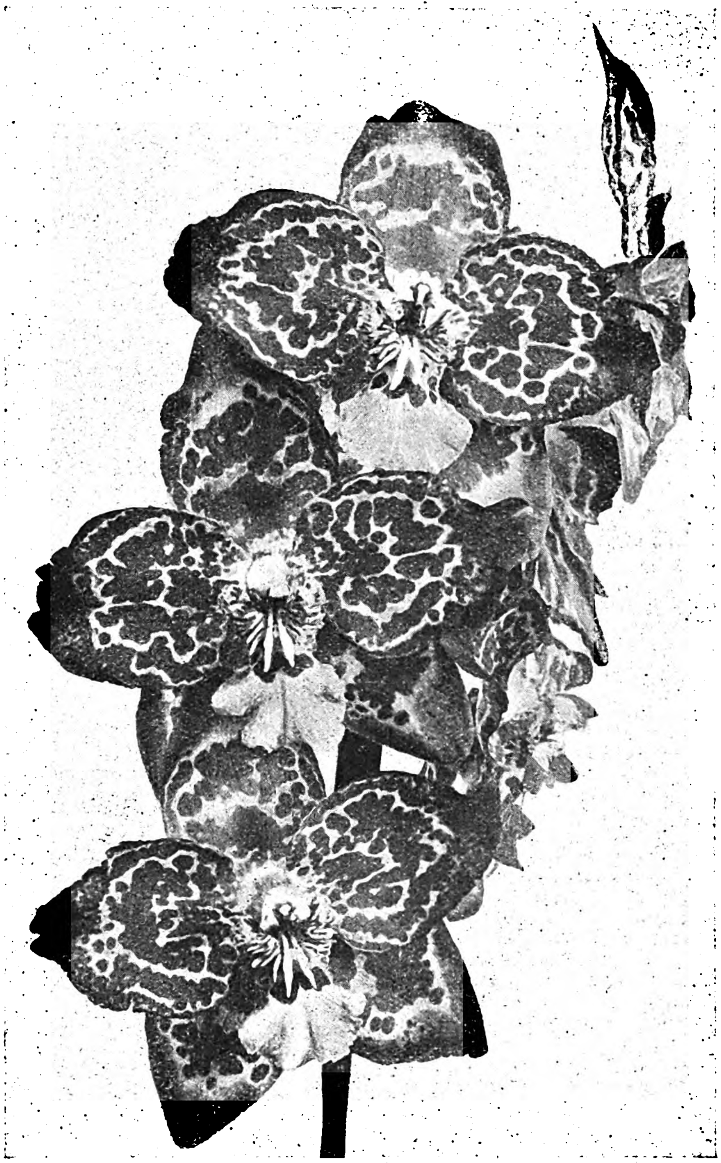

FIG. 131.—ODONTIODA VELASQUEZ.
R.H.S. Award of Merit, March 26. Flowers cream, purple and red.
Shown by G. Mayer, Esq. (gr. Mr. R. Cottam), Wistlers Wood, Woldingham.

Cabbages.—Plants from early-sown seeds, which have been brought on under glass, may now be planted out if well hardened off. These will be in great demand this year, as many of the autumn-planted Cabbages have perished.

Herbaceous Borders.—These should now receive attention. If any of the occupants are overgrown, cut out the centre of the clump with a spade and fill the hole with fresh soil. Give the surface of the border a dressing of old manure, or vegetable or leaf-mould, and point this into the surface, going deeper where space permits, so that vacant spaces may be prepared for planting.

INDOOR PLANTS.

BOUVARDIAS.

BOUVARDIAS are among our most useful decorative cool-house plants, and when well grown make a most useful addition to the conservatory or flowering plant house during the dull winter months.

Propagation is effected from cuttings taken from the old plants in the spring. These should be inserted around the edges of sixty-sized pots containing a compost of loamy leaf-soil, and sharp silver sand, the whole being passed through a half-inch-mesh sieve. After the cuttings have been inserted, place them under a bell-glass, or in a propagating case, keeping them moist and well shaded from bright sunshine until well rooted, when they may be potted singly into three-inch pots, using a compost of good fibrous loam, leaf-soil and sand, to which may be added a small quantity of good peat. After potting, place them in a temperature of from 70° to 80° until well established. It is most essential at this stage to stop the young plants to induce them to break well, and as they continue to make fresh breaks, keep the growths pinched back until a well-balanced plant is produced. Bouvardias should be syringed twice daily at this stage, and afforded plenty of fresh air on all favourable occasions, taking care to avoid cold draughts. When well established in these pots they should be potted on into six- or eight-inch pots, in which they may be flowered. Use a compost similar to that employed at the early stage, but of a somewhat coarser nature, with the addition of a little bone-meal. By the end of July, gradually harden them off prior to putting them out in cold frames in which to ripen their growths. If a frame is not available, they may either be plunged out-of-doors, or stood on a bed of moist ashes, and there treated practically in the same way as Chrysanthemums.

During the periods of active growth Bouvardias should on no account suffer through lack of water, or dropping of their foliage will result, while occasional applications of weak liquid manure should prove very beneficial. They may remain in the summer quarters until September, after which they should be removed to a warm greenhouse in which to flower. After flowering, gradually withhold water, giving the plants a slight rest, following which they should be pruned and afforded more heat, to induce them to break and produce a supply of cuttings.

Bouvardias are subject to attacks of red spider and green fly; the former may be kept in check by regular syringings with tepid water, and the latter by fumigation. Mealy bug will sometimes put in an appearance, and this may be dealt with by sponging with a reliable insecticide, or by frequent applications of methylated spirit to the affected parts, using a camel-hair brush.

Many varieties of Bouvardias have fragrant flowers, and are very useful for buttonholes, bouquets and table decoration. A few of the best varieties are President Garfield, Bridesmaid, Dazzler, Alfred Neuner, Humboldtii, corymbiflora and jasminiflora var. odorata. *E. Baker.*

BEGONIA GLOIRE DE LORRAINE.

THERE is quite a large number of winter-flowering Begonias of considerable merit for colour display in glasshouses during the dull days of autumn and winter, but probably none is more popular, and few more useful than this herbaceous, annual-stemmed hybrid raised by Lemoine from a cross between B. Dregei and B. socotrana. Although the habit of the plant is to produce short, slender, drooping stems, these may be so multiplied by a good system of cultivation that extraordinarily fine specimens are produced. Each slender stem gives rise in the autumn to a graceful, terminal raceme of bright, rose-coloured flowers which persist for a long time and develop in slow succession, giving a period of display covering three or four months. Specimens fully three feet in height and as much through may be produced in a season, and these form objects of great beauty, but smaller specimens from later-struck cuttings are equally useful, flower with the same freedom, and make ideal material for room and table decoration.

At this season of the year the earlier-flowering plants will be past their best and, with a view to getting a stock of good cuttings for next winter's display, a few of the best plants should be cut down and placed in an intermediate house to induce them to make strong basal growths. The production of good bushy plants depends a great deal on the selection of cuttings, and only basal cuttings should be taken; stem cuttings never break satisfactorily, and do not produce such good plants. If there is any difficulty in obtaining basal cuttings, propagation may be effected from leaves, and some growers maintain that better plants are obtained from this method of propagation. Well matured leaves with a small portion of stem attached root readily if inserted in boxes of sand or fibre in a propagating case with a bottom heat of 75° or 80°. The after treatment in either case is the same. So soon as the cuttings have formed roots they should be potted singly into small pots, using a mixture of loam, clean Oak leaf-soil and sharp sand. They should be grown in a house with a temperature of about 60°, and kept so near the roof-glass as practicable, to induce sturdy growth. Where large specimens are required, the plants should be potted on as required into four- or five-inch pots, and finally into six- or seven-inch pots, using a rather stronger compost made up of three parts fibrous loam to one part good leaf-soil, with a liberal sprinkling of sharp sand and a five-inch potful of bone-meal per bushel of the mixture. Good drainage is essential and the soil should be made moderately firm, but not rammed hard. During the summer little fire-heat will be needed, but the plants should be grown on in a fairly warm and slightly moist greenhouse and shaded from strong sunlight. During hot, dry weather, frequent overhead syringings may be practised with beneficial results; great care should be taken that the plants never become dry at the roots, but excessive watering should also be avoided. Little or no pinching is necessary, for well chosen cuttings produce plants which branch naturally and produce bushy specimens. All premature flowers, however, should be picked off until a few weeks before the time that the plants are needed for decorative purposes. So soon as the flowering pots are filled with roots weak solutions of soot-water, alternating with liquid manure, may be given with advantage once or twice a week.

Two pests sometimes attack the plants, red spider and aphis. The former may be kept in check by syringing and the avoidance of arid atmospheric conditions, and the latter by periodical fumigation. *W. A.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CITROSMUM.

FAILURE to flower this very beautiful and easily-grown Mexican species is frequently caused by too much water being afforded at the roots during the winter and early spring months. This plant requires to be grown in a slightly higher temperature than is suitable for the majority of Odontoglossums, while the dry conditions required during the winter months do not adversely affect it as with others of the same genus. It relishes a light position, fairly close to the glass, at the cool end of the intermediate house. Plants that have been kept on the dry side during the winter are now commencing to grow, and the pseudo-bulbs may shrivel a little; this should cause no alarm and water should not be afforded to the roots in large quantities until the flower spikes are seen in the young growths, when ample supplies may be given each time the compost becomes dry. The spikes grow rapidly at this stage and as the attractive and sweetly-scented flowers expand, the pseudo-bulbs soon regain a plump condition.

Annual disturbance of the roots is not advisable or necessary, but any plants that require repotting may be attended to after the flowers are removed, using well-drained, deep pans and a compost of three parts coarse A.1. fibre and one part chopped Sphagnum-moss, adding some broken charcoal to ensure porosity. Firm potting is required and careful watering needed, as with other newly-potted Orchids. When well-established and the new pseudo-bulbs are beginning to swell, copious supplies of water may be given each time the compost appears dry, and at this stage the plants should not be shaded heavily from sunlight, while a good circulation of air is required to assist the ripening of the growths. When this is complete, very little water is required, and then only at long intervals throughout the late autumn and winter months. *W. G.*

WOODLAND GARDEN.

TRILLIUMS.

THE Trilliums comprise a group of woodland plants, mostly natives of North America, several of which are exceedingly beautiful garden subjects and among our most treasured spring flowers. They are quite hardy and easily-grown, but thrive best in moist, shady positions, and should be given a position sheltered from cold winds, which are apt to destroy the pristine beauty of their flowers. Members of the Natural Order Liliaceae, all the parts of the plant are in threes, which gives rise to the generic name of the plant. The characteristic three leaves in a whorl is typical of the genus, and they are borne on stems varying from a few inches to nearly two feet in height. The solitary flower is either sessile at the junction of the leaf petioles, or rises from this point on a slender pedicel.

T. grandiflorum is probably the best known of the genus, and is one of the most desirable hardy plants grown. Anyone who has seen a colony of this handsome species with the attractive pale green leaves surmounted by a beautiful white flower some four inches in diameter, nodding as if in obeisance to spring, will not readily forget the charm of the scene. It is an ideal plant for massing in woodland glades, and where the soil is moist and rich in humus it grows with remarkable vigour and increases from year to year. Of the numerous forms of this species the variety roseum is very distinct and a pleasing variation from the type, the flowers opening a delicate pink and deepening to a rose tint with age.

T. stylosum is another vigorous-growing species which thrives under the same conditions as T. grandiflorum. The flowers are somewhat smaller and of a rosy-pink colour, and its season of display is later, often extending into June. T. sessile is also a robust-growing species, and although not so attractive in point of beauty as the afore-mentioned, it has the charm of delicious fragrance. The flowers are quite sessile in the axils of the leaves, which gives the plant a rather stiff appearance. T. s. var. californicum is of more graceful habit and a better garden plant. It bears variable, creamy-white flowers, which are slightly claret-tinted at the base and, like those of the type, fragrant.

T. erectum has dark green, spreading foliage and rather showy flowers of a reddish-purple colour. There is also a form of this species with nearly white flowers, the petals, however, being tinted with red at the base.

Another species of merit is T. cernuum, producing pretty, nodding, white flowers on stems from a foot to eighteen inches high which often grow two or three together.

Three dwarf-growing species may be mentioned which prefer somewhat drier positions and make charming little plants for selected nooks in the rock garden, namely, T. undulatum, with spotted, ovate leaves and showy, white flowers, the perianth segments being heavily spotted with crimson at the base; T. ovatum, a dwarf plant, the three leaf segments forming a complete circle around the stem, from the centre of which the almost sessile flowers appear, pure white at first but developing a reddish tint with age; and T. nivale, a miniature species and one of the first to bloom, its pure white flowers appearing on tiny stems in April. *A. W.*

TREES AND SHRUBS.

DOUBLE-FLOWERED CLEMATISES.

THE named varieties of the florists' Clematises are mostly grouped in sections, according to the species used in their creation by the hybridists. The Jackmanni forms owe their origin to a cross between C. Hendersonii and C. lanuginosa, raised in the nursery of Messrs. George Jackman and Son, of Woking, in 1860.

Most of the double-flowered varieties have originated from C. florida, a native of China, and probably of Japan also. Thunberg was the first to introduce C. florida to our gardens in 1776. This, as with numerous other of Thunberg's introductions, was the progeny of plants cultivated for many decades in Japanese gardens.

The plant with double flowers introduced by Robert Fortune from Japan, and figured in *The Gardeners' Chronicle* for 1863, p. 676, as Clematis Fortunei, is now regarded as a cultivated variety of C. florida.

Considering their highly decorative character and beauty, it is rather surprising that the hybridist has not paid more attention to the raising of double-flowered varieties. As a matter of fact, Clematises with double flowers were more in evidence in bygone years, when specimens cultivated in large pots, and trained on a balloon-shaped wire framework, were a feature at horticultural exhibitions.

It must be admitted that the double-flowered varieties of the Florida section are not, perhaps, quite so hardy and free-growing as the single-flowered varieties of the C. lanuginosa group. The ardent and skilled plant cultivator is not usually discouraged by such problems, especially as in this case we have the longer lasting quality of the double flowers.

When selecting stations for planting double-flowered Clematises, choose the more sheltered positions, such as a wall or fence with a western aspect, and the side of an arbour or trellis screened from the east and the mid-day sun.

Cultivated in pots for the decoration of the cool and unheated greenhouses, or planted out as climbers in the borders of the cold greenhouse, they are of the greatest value.

The large-flowered, double Clematises produce their flowers from the old wood during June and July in the open air. Under glass, the flowering season is obviously earlier, according to the temperature of the house and when the pot plants are brought into the greenhouse from outside. Although grown under glass for several months of the year, the best results are usually obtained when the plants, after flowering, are placed in a sheltered place outside to ripen the new growths of the season.

The double-flowered Clematises require very little pruning, beyond the removal of old flowers and weak wood at the end of the flowering season. In February, take off two or three inches of the thin ends of the shoots, cutting them back to a healthy bud.

A selection of the best double-flowered varieties should include Beauty of Worcester, bluish-violet, with white stamens, producing both double and single blooms; Belle of Woking, silvery-grey; Countess of Lovelace, bluish-lilac; Duchess of Edinburgh, large, pure white, with a delicious perfume; and Lucie Lemoine (Fig. 132) the best double white for outdoor cultivation. *A. Osborn.*

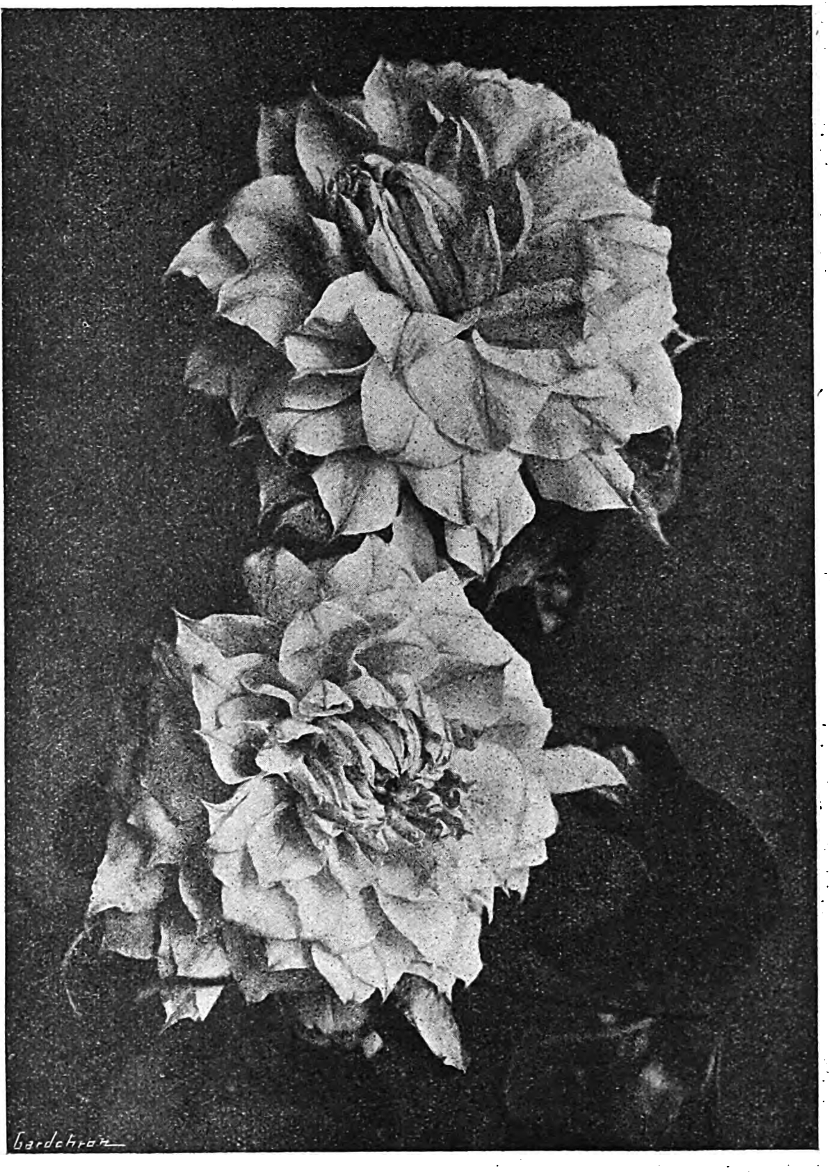

FIG. 132.—CLEMATIS LUCIE LEMOINE.

PHILESIA BUXIFOLIA.

IT is agreed generally that the past winter has been one of unusual severity, and although we may experience yet more severe frosts than have occurred in many localities, it is interesting to note from time to time the behaviour of certain plants under trying conditions. The subject of this note is one which cannot be termed hardy, except in the more favoured districts in the south and west. It is understood that hardiness is referred to here as being an ability to withstand our sudden changes of climate; not solely a low degree of temperature, but also fog, rain and other forms of atmospheric humidity and light obstruction, coupled with hot sun and unexpected rises in temperature at unfavourable times.

Philesia buxifolia is a fairly well-known dwarf shrub which is interesting if only for the fact that it belongs to the Liliaceae, a family of diverse characteristics so far as habit is concerned, although usually associated with subjects of a bulbous nature. In passing, it may be recalled that Philesia is so closely allied to Lapageria, a Liliaceous climber, that the bigeneric hybrid, Philageria Veitchii, was raised by the union of the species with Lapageria rosea. The hybrid favours Philesia, having similar leaves and a non-climbing habit.

P. buxifolia is admirably suitable for the rock garden, forming a low, horizontally-spreading shrub of less than a foot in height in gardens. The stems are stiff, and bear alternate, narrow, rolled leaves, about one inch to one-and-a-half inch long, dark green above and whitish below. The flowers are borne singly at the tips of the branches, and are tubular, about one-and-a-half inch to two inches long, and deep rose, tending towards crimson, in colour. In favourable seasons the flowers may be followed by the rough-surfaced, oval or rounded berries. The species occurs from the Straits of Magellan to Chiloe and Valdivia, thus covering about twelve degrees of latitude along the coast of Patagonia, and perhaps extending into Chile proper. We are indebted to William Lobb for the introduction of this useful shrub in 1847, through Messrs. Veitch of Exeter and Chelsea, although it had been previously noted by several botanical collectors. Six years after its introduction the species was exhibited in flower at the old Chiswick Flower Show.

The specimen under consideration is planted on a rock garden (within ten miles of Manchester), in a cool, shady and sheltered position, at the base of a large boulder, and with a north-west aspect. The soil is chiefly peat and leaf-mould. This situation and compost unwittingly approximate to that advised by Farrer in his *English Rock Garden*, where he remarks that P. buxifolia requires a lime-free medium, plenty of water at the roots in summer, and pieces of sandstone mixed with the soil so as to absorb moisture and afford a secure root-hold. The plant has been in its present position for three winters, during which time it has remained untouched by frost and has increased slightly in size. It would appear that the species does not flower very freely in the open and rarely, if ever, sets seeds, but this is a point upon which it would be interesting to have the experiences of others. The fact that growth is comparatively slow probably accounts in large measure for its ability to tolerate our climate, the new growths having been thoroughly ripened each year before the winter sets in. *L. B. C., Cheshire.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

CHILE AND THE ANDES.*

No. IX.

LEUCOCORYNE OR GLORY OF THE SUN.

THERE were some excellent flower stalls in Valparaiso (Fig. 134). They seemed to do good business, especially with great sheaves of Carnations of the rather coarse, ragged types that one finds in French flower markets. There were Gladioli too, of a big, heavy type—the Primulinus hybrids do not appear to have arrived in Chile. Most beautiful of all were great masses of the lovely, snow-white Watsonia Ardernei. But what interested me most in the flower market, and what I watched closely from day to day, were the bunches of wild flowers that came in from the country. I have a passion for markets. On arriving in any new town in a foreign country—in fact, any town, foreign or English—I always make for the market long before I think of visiting the museum or the cathedral. Museums are all very well, but there is so little in them of which one can become possessed by honest means.

Among markets, on the contrary, I have never gone unrewarded for my curiosity. In the market of Palma (Majorca) I bought the best gardeners' knives in the world, and in the adjoining fish market I saw the Mediterranean octopus or squid, and thereby learned—after battling with the head waiter of my hotel—what excellent eating the octopus is. From Mr. David's world-famous bookstall in Cambridge I have profited much, and at a plant and flower stall near by I often enjoy a "busman's holiday," so to speak, among the alpines.

And so it was at Valparaiso. Soon after our arrival there appeared on the street flower stalls, bunches of Leucocoryne in three distinct colours, lilac, white and blue. I have referred to Leucocoryne ixioides (odorata) in an earlier article, a pretty, pale lilac species which we found in the hills outside the town, but those of the market were infinitely superior to any we had yet seen. The finest of them was the blue one (Fig. 134). The white and the lilac were lovely flowers, and a bunch of either, shown before the R.H.S. would certainly have got an Award of Merit, and created a sensation. But the blue one (Fig. 134) was a flower of startling and first-class merit. Let me describe it. Imagine a wiry, eighteen-inch stem carrying in a loose umbel or head of anything up to six or eight Chionodoxa Luciliae blossoms, the same shape and texture, the same size, or often considerably larger, and the same splendid clear china-blue passing to a white centre, but with three yellow stamens lying out of the perianth; but it is a far lovelier thing than Glory of the Snow, for its length of wiry stem gives it an added grace, both growing and when picked, while as a crowning glory it is deliciously fragrant with a rich, sweet, Almond scent. Chionodoxa Luciliae is called Glory of the Snow, and I shall call this Leucocoryne—so like Chionodoxa in many ways—Glory of the Sun. I bought a bunch or two and they lasted well in water for a week, which, to my mind, is an ideal time for a cut flower to last. I dislike any flowers which become collectors of dust.

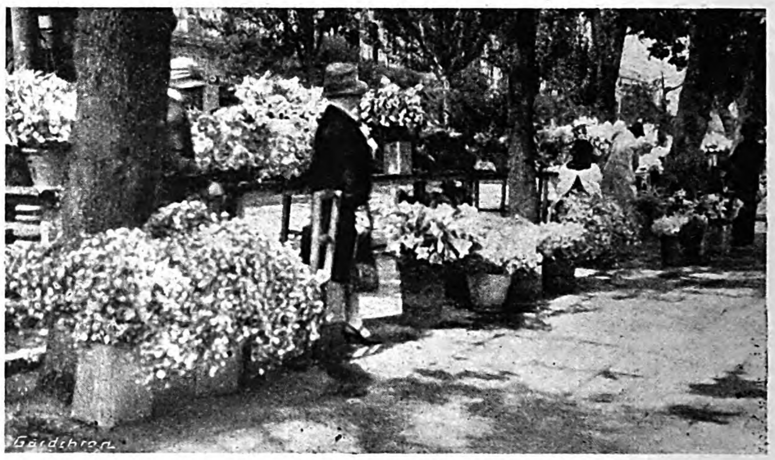

FIG. 133.—A CHILEAN FLOWER MARKET.

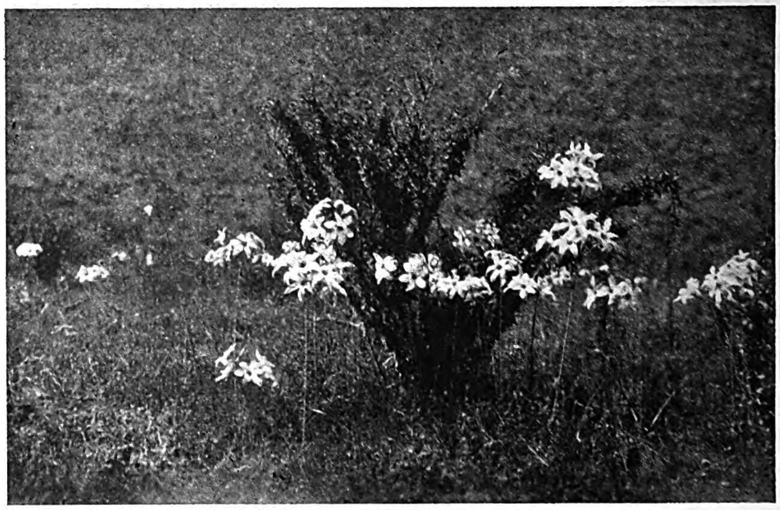

FIG. 134.—LEUCOCORYNE IXIOIDES (ODORATA) GROWING WILD AT COQUIMBO.

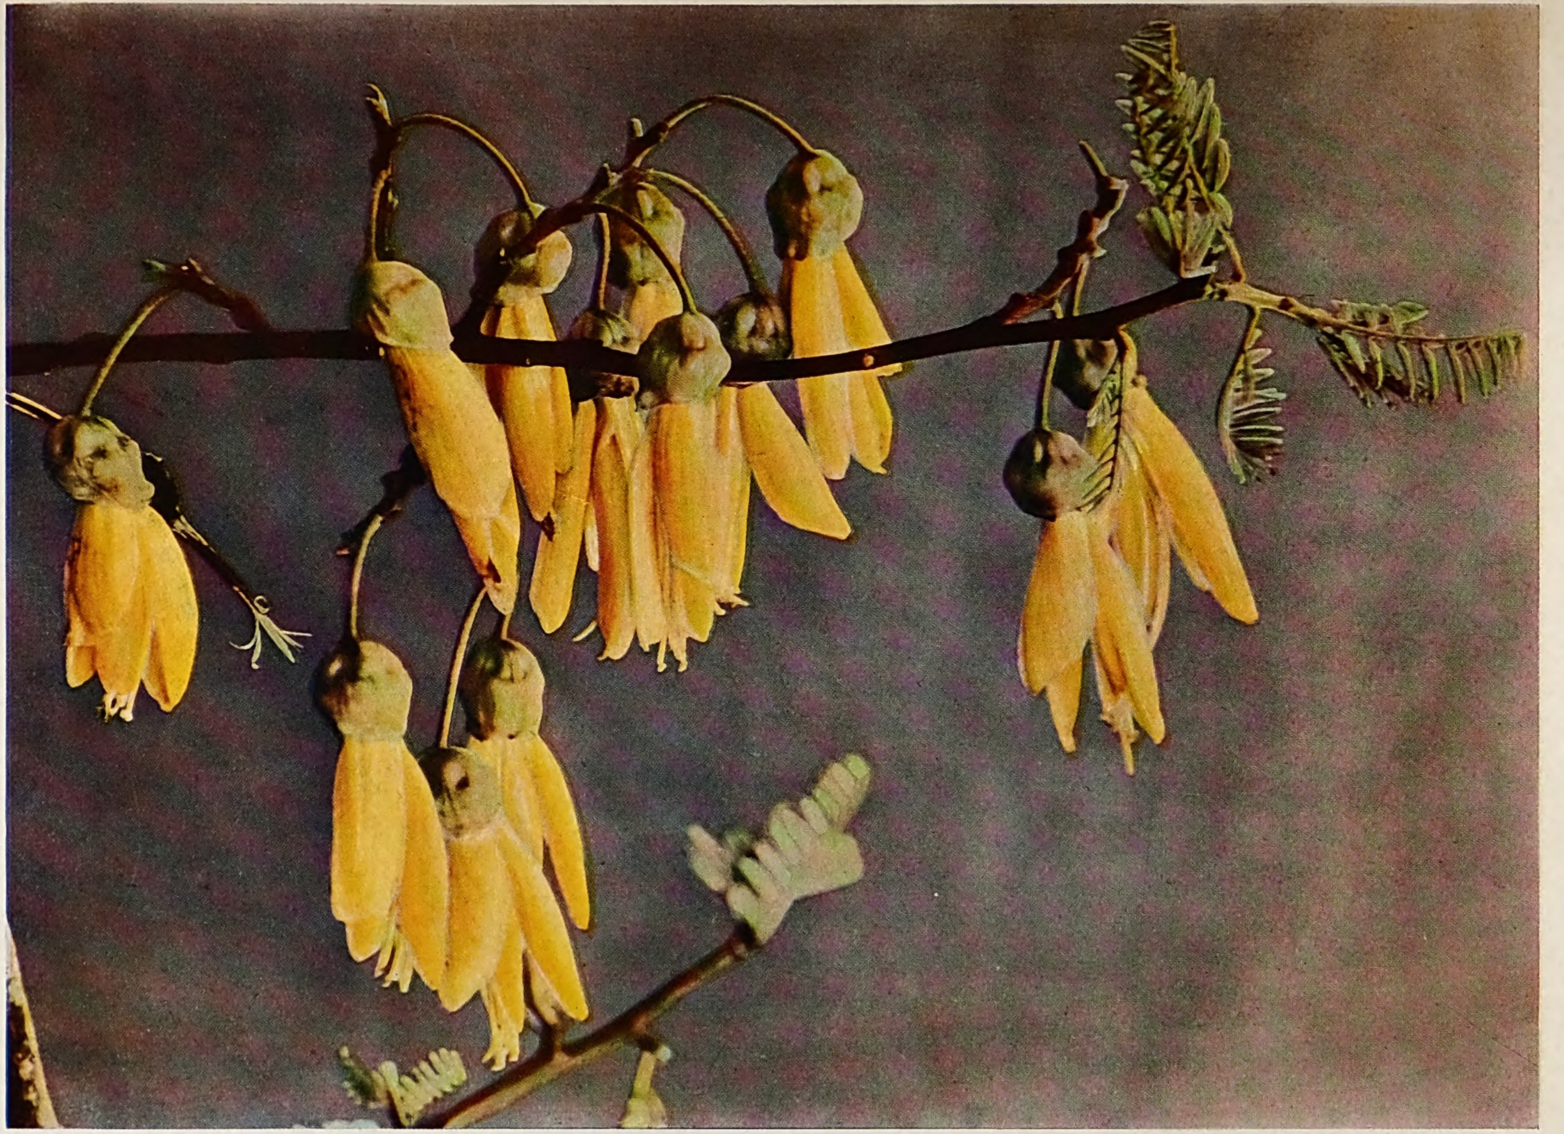
Here was a plant to "go for" if ever there was one. It had beauty of form and colour, fragrance, and a good stem, and apart from my own opinion of its beauty, there was sure evidence of a popular appeal as well. A wild flower which can be sold in the streets *in its own country* is a flower to reckon with. We made enquiries as to where this Leucocoryne came from—we had seen none growing in the neighbourhood—and found that it was sent from Coquimbo, a couple of hundred miles northward up the coast, and to Coquimbo we decided to go forthwith; but first we must go down to Santiago and get in touch with Professor Fuentes, of the Herbarium at the National Museum. To Santiago we went, a beautiful town with fine parks and gardens, one of the best clubs in the world, and always and above all the Andes towering superbly in the background. A friend lunched us at the Union Club, an amazing place, far more magnificent than the London R.A.C., but in excellent taste. From the roof garden of the club we had our first real glimpse of the Andes. From Valparaiso we had seen them, a hundred miles or so away, vast, but dim and remote. On our arrival in Santiago it was misty, but on the Club roof our host pointed, and we looked—and looked—and looked. Ten miles or so away foot hills rose and melted into tender vagueness, and looking up to where we expected to see high mountains, was only misty vagueness; then, quite suddenly, infinitely higher than we had yet looked, far higher than we could have expected to see mountains, the Andes sprang into focus, vast and beautiful, too enormously high and vast to be real, almost crushingly beautiful and terrible.

In the centre of Santiago is the Santa Lucia hill, an abrupt young mountain of rock, famous in Chilian history as the centre of a great battle, between Valdivia and the Araucanian Indians

---

* Previous articles on Mr. Clarence Elliott's expedition were published in our issues of November 12 and 26, December 10 and 24, Vol. LXXXII; January 7 and 28, Vol. LXXXIII; July 28, Vol. LXXXIV; and March 23, Vol. LXXXV.

Supplement to "The GARDENERS' CHRONICLE."



SOPHORA TETRAPTERA.

Santa Lucia is bigger than it appears from a street or two away. A carriage drive winds up its sides. It has been planted with trees, Eucalyptus and Mimosa, etc., terraced and planted with flowers; little paths have been made and flights of steps cut in the rock. Wistarias and Begonias go clambering up and Mesembryanthemums and Ivy-leaved Pelargoniums go scrambling down its cliffy places. There are restaurants, arbours, bandstands, terraces for dancing, and shady seats, and gardeners are ever busy with rake and garden hose.

On our first evening we walked up to a terrace near the summit of Santa Lucia to see the sun set, an impressive view out across the city with its domes and towers and steeples, big Government buildings and a budding sky-scraper or two, and then beyond the town a wide rich plain and over that the appalling snow wall of the Andes, which, for a few minutes, became glowing rosy-pink and amber as the sun went down. Suddenly the light faded out to a ghastly, cold blue. In a few minutes it was night, and we watched Santiago light up; street after street began to blaze and twinkle below us, sky signs grew busy, a mile or two of street lamps flashed out on the far side of the city, sweeping in a wide curve up a hill that faced us, to a hillside restaurant which itself blazed out with electricity. In ten minutes, from warm, glowing sunset, it had become dark and bitterly cold, and we hurried down to lighted streets and our centrally-heated hotel. Sunset and the lighting up of Santiago from Santa Lucia hill have led me astray. I ought not to have tried to describe them. I apologise. An American I met in the voyage out did better. He wanted to tell me about a sunset he had seen somewhere in the Mediterranean, but the memory of it froze him to incoherence. All he could get out was "My! you should have heard the passengers going on about it"—which really conveyed quite a lot. *Clarence Elliott.*

ALPINE CAMPANULAS.

The genus Campanula embraces a very large number of species, which vary widely in height, habit of growth and form, and are suitable for a variety of purposes. Some, like C. pyramidalis, and the lesser-known C. Vidallii, respond admirably to pot culture and are useful for conservatory adornment, and others, notably C. latifolia, C. lactiflora and C. persicifolia, are invaluable for the borders.

But it is the purpose of these notes to deal with the Campanulas of low stature, whose name is legion, but among which are many of outstanding merit—indispensable for the rock garden—and in the majority of cases of extremely easy culture, although, of course, there are some which only give of their best when afforded special cultural conditions, such as are embodied in the moraine. Among these, the diminutive C. Allionii, one of the earliest to flower, comes to mind first. This gem succeeds best in the moraine, and there will form small tufts of grey, downy foliage, and during May and June will produce its single blooms, large in comparison to the size of the plant, and of a beautiful rich lilac-blue, on stems hardly one inch long. Then there is C. Zoysii, a delicacy much sought after by slugs, as also, incidentally, is C. Allionii, and therefore, in its favoured position in the moraine, it must be carefully guarded from these marauders. C. Zoysii is undoubtedly one of the most charming, and also one of the quaintest-flowered of the race. It forms close tufts of bright and glossy green foliage, and bears, late in the season, dainty little sprays of delicate flowers of a delightful shade of pale lavender-blue, narrow and tubular, and each with a peculiar five-lobed, puckered mouth. Another species worthy of moraine treatment is the July-flowering, low-growing C. arvatica (syn. C. acutangulare), whose open, star-like blooms, borne in small sprays, are purple in colouring, while the rare C. excisa, whose violet-blue bells are quaintly perforated at the base of each segment and borne on dainty stems of three inches or so in early July, may also be included.

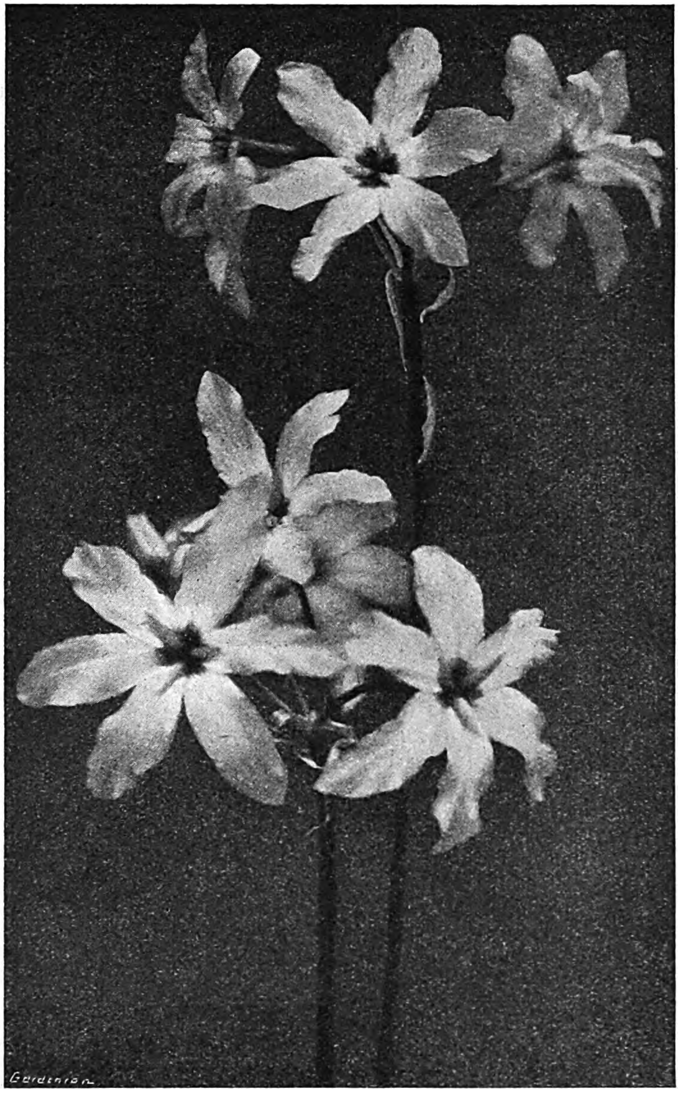


FIG. 135.—LEUCOCORYNE IXIOIDES (ODORATA.)

R.H.S. Award of Merit, March 26. Flowers blue and white.

Shown by Mr. Clarence Elliott (see pp. 252 and 262).

The larger percentage of the alpine Campanulas, however, ask for nothing more than medium, loamy soil and a moderately sunny crevice or ledge, from which it will be seen they are admirable for furnishing rock walls. For producing a massed effect, none is more useful than the popular C. carpatica which, although included here as a rock garden plant, is also very serviceable as an edging plant, or for grouping at the front of herbaceous borders. It is extremely prolific in the production of flowers, and also of seeds, plants from which are fully grown and flower with characteristic freedom in the second year, although propagation may also be accomplished easily by division or cuttings. C. carpatica blooms throughout July, the wide-gaping chalices of violet-blue being borne on nine-inch stems so freely as to completely hide the neat tufts of foliage beneath and to form an unbroken sheet of colour. As might be expected with so easy and popular a plant, there are many distinct forms available, also a few hybrids; among the latter, mention may be made of C. Fergusonii and C. Hendersonii, both very beautiful, but not easy to obtain, nor easy to grow. Among the various forms of C. carpatica there are several white ones of high merit; var. alba is the white counterpart of the type, and var. Little Gem is dwarfer, with snow-white blooms, while the flowers of White Star are of grand size.

Other notable forms of this species are var. Isabel, a distinct sort with extra large flowers of deep violet colouring; var. pelviformis, with flattened, lilac blooms; var. pallida, pale blue, and var. Riverslea, deep blue. Opinion is divided as to whether the lovely C. turbinata is a form of C. carpatica or a distinct species. However, it is one of the most prized, for it forms a dense mass of grey, hairy foliage, close above which are borne, in lavish profusion, large, open saucers of a delicate china-blue shade.

One of the distinct groups of these alpine Campanulas embraces such treasures as that popularly known as C. Bellardii var. Miranda, C. pulla, C. pulloides and C. pusilla, all indispensable. C. Bellardii var. Miranda, one of the late Reginald Farrer's introductions, ranks among the most beautiful; it is of dwarf and compact habit, forming close tufts of foliage which are hidden from view during June and July by the myriads of nodding, silvery-blue bells on short, slender stems. It is easily accommodated in well-drained, loamy soil, and is a good perennial. C. pulla is dwarf and free, its drooping bells of satiny-violet being produced abundantly on slender, three-inch stems above the carpets of bright green and glossy leaves during July; the variety lilacina is worth planting for its lilac-coloured blooms. C. pulloides is even more desirable than C. pulla, if that is possible, for it is taller, and the larger and shorter bells are rich violet, with a satiny sheen; it is an extremely beautiful garden hybrid. C. pusilla has many varieties, is easily cultivated, free-growing, dwarf, with small lavender-blue bells. Among its desirable forms are the charming, white-flowered variety alba; var. lilacina, delicate lilac, faintly tinged with pink; var. Miss Willmott, pale lavender-blue, and var. pallida, a pale blue form.

And then we come to C. garganica and its several varieties which are valuable for the furnishing of sunny rock crevices, both on the rock garden and the rock wall. They are all very popular and much prized on account of their free-growing and free-flowering propensities, the chief characteristic of the blooms being their star-like form. Those of the type are of electric-blue colour, borne on flattened branches radiating from the central tuft of small, heart-shaped leaves. Var. W. H. Paine, a well-tried and popular form, has rich violet-blue, white-eyed flowers; var. alba is the white form; var. erinus has glossy-green leaves and rich china-blue flowers with pale eyes; and var. hirsuta has grey, downy foliage and lavender-blue stars.

A very choice alpine Campanula of hybrid origin is C. G. F. Wilson, whose large, violet-blue flowers are borne freely on three-inch stems during July; while C. haylodgensis, another hybrid, is also very beautiful, having glossy, pale green foliage and erect, open cups of clear blue. C. Hallii, raised by Mr. A. J. Hall, of Harrogate, has lovely, snow-white little bells on three-inch stems, and is well worth securing; C. R. B. Loder, is an uncommon, June-flowering sort which forms close tufts of pale green foliage and has lavender-blue, semi-double flowers on slender stems four or five inches high; while C. Stansfieldii is another hybrid of high merit which bears, on spreading stems, open bells of soft violet.

C. isophylla is equally at home on the rock garden as in the conservatory or cottage window, and is well worth a place, while C. macrorrhiza, a dainty Harebell from the Riviera, is also valuable, bearing as it does its small, open, vase-shaped, deep violet-purple blooms in gay profusion during June and July. C. Portenschlagiana is an indispensable carpeting species, for it forms large mats of dark green foliage, hidden in July beneath the rich violet bells; while C. Raineri is also very choice, forming close, low tufts of ash-grey foliage, above which, on very short stems, the beautiful china-blue cups are carried.

No selection of alpine Campanulas would be complete without C. Tommasiniana and C. Waldsteiniana, two of the choicest. The former species forms masses of low, bushy stems, five inches or so high, which are set with narrow, toothed leaves, and bear long, slender, tubular and drooping blooms of a delicate shade of lilac. C. Waldsteiniana is of very dainty appearance, its starry, violet and pale-eyed flowers, borne after the habit of C. Tommasiniana, being produced freely during July.

As the various dwarf Campanulas given above by no means exhaust the list of those available, some realisation of the size and variety of this group may be obtained. The majority of them set seeds fairly abundantly and, if these are sown in early spring and the seedlings grown on in small pots, plants of suitable size for permanent planting may be obtained by the autumn or following spring. Many kinds are easily increased by division or, if this is not advisable, cuttings may be rooted in a sand-bed in a cold frame and a stock so secured. All the species enumerated above are hardy and flourish under outdoor conditions in this country, while some of the choicest, such as C. Zoysii, respond well to pot culture, and may well be employed for such purposes in the alpine house. When so treated no attempt should be made to force them, as this will result in spindly growth and loss of bloom; they should be allowed to develop naturally in a cold frame and only removed to the alpine house when the flower buds have formed.

So it will be seen the Campanulas form a very fascinating group of rock plants, from a decorative point of view equalling the Primulas, Dianthuses, Gentians and Saxifrages. *M. W.*

ASIATIC PRIMULAS.

Nearly one-third of the recently issued volume of the R.H.S. *Journal*[*] is devoted to the Primula Conference, which was held during the Chelsea Show of 1928, and to the papers prepared for it. Of these, the paper by Wright Smith and Forrest on "The Sections of the Genus Primula," and that by Handel-Mazzetti, of the Natural History Museum, Vienna, on "The Natural Habitats of Chinese Primulas," are of paramount importance to students and cultivators alike.

The first is the latest effort of science in the remarshalling of the genus, which has undergone considerable extension and some modification in the fifteen years which have passed since Bayley Balfour proposed a tentative revision[†] of Pax's original Monograph.[‡] Originally issued as a separate number of the *Notes* from the Royal Botanic Garden, Edinburgh[§] with two plates, the revision by Smith and Forrest reappears in the R.H.S. *Journal* with minor modifications and a few alterations, as well as an illuminating series of plates of various Primroses. These are due, we are told, to the generosity of the Royal Horticultural Society, and have been prepared from photographs taken in China by Forrest and Handel-Mazzetti, or specimens growing at the Edinburgh Botanic Garden or at Wisley. Broadly, these photographs, which will be of unique interest to students of the genus, are of a very high order and redound to the credit of all concerned.

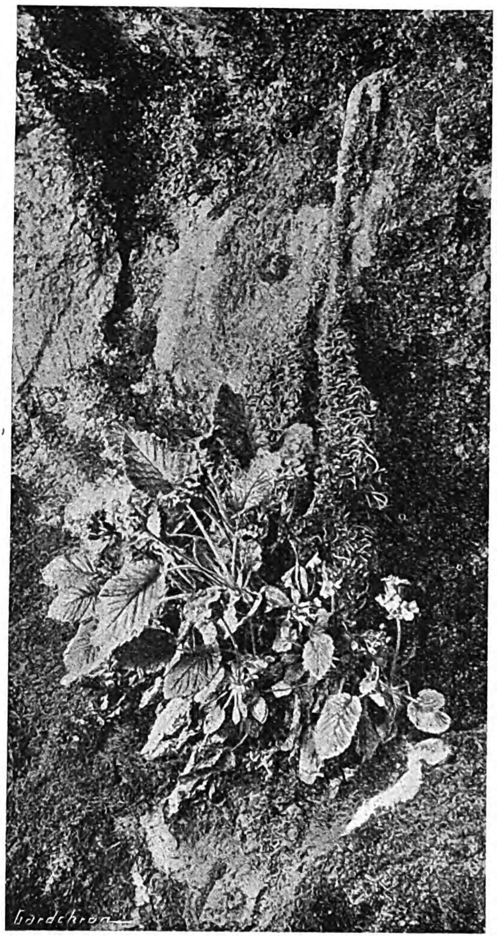

FIG. 136.—PRIMULA FORRESTII.

An old plant on the Lichiang Range, Yunnan; alt., 12,000 feet. Photographed by Mr. G. Forrest, 1906.

Among them there is a wonderful photograph (Fig. 136) of a patriarchal specimen of P. Forrestii, illustrating its peculiar habit of growth and enabling us to appreciate the discoverer's estimate of this species as rivalling human beings in the allotted span of life. The photograph was taken when the explorer was on the Lichiang Range, in June, 1906, at an altitude of about 12,000 feet, and he stresses the point that there is nothing abnormal about the particular specimen, which is but one of many of corresponding habit and great age found in similar situations. The fact that P. Forrestii commonly throws out two whorls of foliage annually makes an estimate of the approximate age of individual plants comparatively easy, and when, on Forrest's return home, the particular specimen illustrated in the photograph was critically examined at Edinburgh, Sir Isaac Bayley Balfour and the explorer jointly reached the conclusion that the rings of scars on the basal part of the ligneous rootstock and the whorls of induviae on the upper part indicated that the plant must have been at least fifty years old.

Forrest has observed that, like most of the genus on the ranges of North-west Yunnan, P. Forrestii is gregarious, forming large colonies on the limestone ledges of the cliffs on the eastern flank of the Lichiang Range at from 10,000 feet to over 12,000 feet altitude. He has noticed that it assumes the pendulous habit so clearly shown in the photograph when growing in the dry crevices of overhanging cliffs, and in such situations the lower part of the stem will often be very woody. These ligneous specimens, however, are not so free-flowering as those in more open ledges, where, rooted in crevices of the rock, the plants are nourished by a certain amount of humus, and flower profusely. In such situations Forrest often found his Primrose growing in company with the beautiful Cypripedium tibeticum, whereof the deep maroon blooms are in happy contrast to the light green foliage and orange-yellow flowers of the Primrose. From November until March the Lichiang Range is heavily coated with snow down to about the two mile level, and in some years even below that, so that in its higher stations P. Forrestii is under snow in winter.

The most successful example of the acclimatisation of P. Forrestii in England, and the oldest is, no doubt, at Caerhays, where, within a few yards of sea level, the plants seem quite at home on the vertical faces of stone walls.

The picture of P. Agleniana (Fig. 137), reproduced from a photograph of a specimen which flowered in the Edinburgh Botanic Garden last year, will assuredly whet the interest of the many who have still to see this fine Primrose in the flesh, and as it also has taken root in the garden at Caerhays Castle, from seeds sent by Forrest, who originally discovered the plant so long ago as July, 1905, and thanks to the generosity of Mr. J. C. Williams, it is now in other gardens, and may make a public appearance before long[*]. The queen of the Nivalid section of Primula, if not, indeed, of the genus, its virtues have been proclaimed by the four European explorers who have seen it—Forrest, Farrer, Ward and Handel-Mazzetti, each in his own way; and with the photograph before us we can appreciate the enthusiasm which sent the greatest of horticultural word-spinners into raptures over the plant which he found on the Shing Hong pass over the Salween-Nmai Kha divide on his last venture. "What are you going to say, then, to a great clumping species which starts as a Sonchifolia, and then sends up, with the leaves, an eight-inch stem, from which develop two to three pendant flowers in the purest Sikkimensis style, but about twice the size of any Sikkimensis ever bloomed, and more Byzantinely bell-shaped? And of the most solid, carved ivory-whiteness, very rarely and very faintly tinged with that lovely pink which my paintbox calls rose antique; with buds like drops of sunset and calyces of maroon-crimson, and a vivid blush of pink or apricot over the tube."[†]

Of the other photographs, with which the papers are so liberally embellished, it is pleasant to see that old friend, the diminutive P. Reidii caught, *en famille*, at precisely the right moment; but to cultivators the *clou* of the illustrations, other than that of P. Forrestii, will doubtless be the delightful pictures by Handel-Mazzetti of P. Beesiana and P. chrysophylla at home.

[*] In his recent lecture at the R.H.S. Hall, Prof. Wright Smith announced that Capt. Kingdon Ward had found a yellow-flowered form of P. Agleniana.

[†] *Farrer's Last Journey*, p. 193.

The paper by Dr. H. Handel-Mazzetti on "The Natural Habitats of Chinese Primulas" is most interesting and, indeed, most enlightening on a subject about which cultivators are for ever seeking information. Field tickets are necessarily brief, and in many cases are not accompanied by photographs, nor subsequently amplified; so that much is left to the imagination of the cultivator. In his paper, however, Handel-Mazzetti, in simple language contrives to convey a happy verbal picture of the conditions in which many of the Chinese Primroses grow. Of P. sonchifolia, he tells us:—"On May 18 (1914), on another mountain in Szechwan, there was at the same altitude (14,200 feet) no snow at all and Primula sonchifolia, Franch., was in full flower. It is indeed especially fitted for early flowering. The broad and thick, succulent leaf-sheaths, and the close-set leaves not quite unfolded yet, with the flowers embedded between them, as in a warm nest, offer an effective protection from cold winds, and the growing place is selected with a view to that, in the deep ground of dense Fir forests or under a still closer roof of gnarled Rhododendron trees about thirteen feet high, amongst thick cushions of hepatics and Dicranum perfalcatum, Broth., and on deep black soil covered by Rhododendron leaves, and similar to the alpine turf, neutralising the differences of the various mineralogic substrata. There it flowers alone so early, sometimes together with Chrysoplenium Davidianum, Decne., and only on quite open places warmed by the sun there are some few other flowers opened at the same time."

Primulas of the Nivalid section are generally so unresponsive to cultivation here that Handel-Mazzetti's observations of them will be read with especial interest:—"They (the tall Nivalids) belong to a plant formation which does not conform with any other one known to me from anywhere else, and which I was obliged to give the special name of 'leaf-mould pasture.' The soil here consists chiefly of remains of plants, half-rotten, and under these completely rotten leaves, and especially the leaf-sheaths of the many deep-rooting plants belonging to most various families, and having the bases of the stems enveloped in such. . . . . A considerable part (of the flora) is constituted by the Nivalid Primulas themselves; P. sinoplantaginea, P. leucochna and less markedly P. szechuanica which inhabits also firmer humus on clay-slate. This plant formation is often found on steep slopes and on remarkably dry soil so that it cannot be counted to the moors, although in composition it is somewhat similar to them. It can easily be understood that plants especially adapted to so particular a formation are difficult to cultivate. . . . . Before I treat of other high alpine Nivalids, I must mention one more subalpine one, P. chionantha, perhaps the most vigorous. I only saw it fruiting amongst high herbs along streams, always on markedly vegetable substratum, especially between the roots of Rheum officinale."

Of P. Agleniana (Fig. 137), we learn that:—"In a small valley, one of the last ramifications of the deep-cut Ch'iontson-lumpa, on the way from the Salwin to the Irrawaddy, which, although it rained deplorably and the river was the only road, impressed me deeply as being one of the most beautiful flower gardens, it stood in masses at an altitude of 11,500 to 13,000 feet, on rather stony soil, protected as a bud by its large leaf sheaths, and now partly by branches, and the roof of leaves of dwarf Cherry scrub, which is peculiar to this country, and Rhododendrons, at the lateral slopes near the stream, blooming in the alpine spring, but much after the snow melted."

Scattered over the pages of this paper cultivators will find many observational details which throw light on obscure points. It is often asked, for instance, whether P. sikkimensis and P. secundiflora are naturally lime-haters, and it is evident that they are not. "Rock plants of the temperate zone are: P. aromatica, in damp niches and crevices of limestone rock, P. Forrestii and P. rufa in crevices and ledges of limestone rocks, but on drier places, and their long lignescent rhizomes enable them to expand over the barren rock. P. yunnanensis is often a true rock plant content with the smallest cavities on perpendicular limestone rock-walls offering some nutrition. It is not, indeed, confined to such places, but found also on earth of rough broken edges of roads, and in the sandy soil of Pine forests, but always as a decided limestone plant. P. pulchella is similar in its requirements, inhabiting the same localities, perhaps confined more to hard, stony soil. Like P. sikkimensis, the related P. vittata is common to both zones (temperate and alpine), inhabiting swampy places on limestone ground. The closely-related P. secundiflora is subalpine and alpine on both limestone and clay-slate on deep humus of depressions and moory edges of clumps of Rhododendrons." On the other hand, the position of P. nutans in regard to lime seems as yet indefinite.

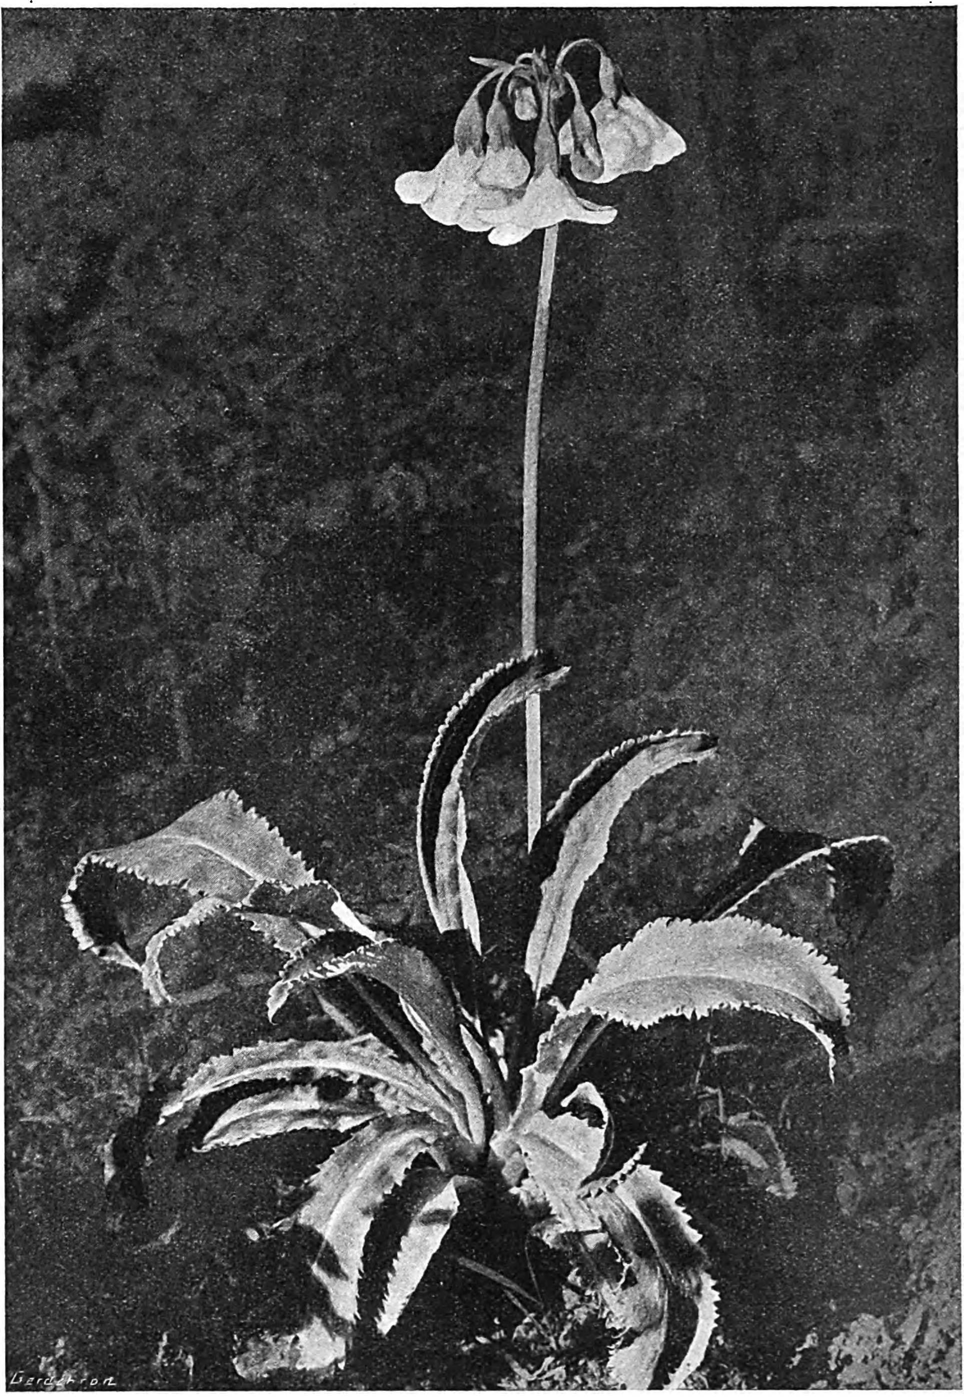

FIG. 137.—PRIMULA AGLENIANA.

Flowering at the Royal Botanic Garden, Edinburgh, in 1928, from seeds collected by Mr. G. Forrest.

No one can yet state how many of the Chinese and Tibetan Primroses now available are likely to be found in private gardens in ten years' time. Only experiment can solve the riddle, and so long as keen amateurs exist, so long, doubtless, will endeavour be made to find out the conditions these alpine and sub-alpine species will tolerate. If, as seems likely in many cases, the stock can only be kept going by constant renewal, the species concerned will remain in the care of interested amateurs and botanic gardens very much as the majority of the Meconopsis genus remains now. But so many patient, clever men are now interested in the cultivation of Primroses that we may look with tolerable certainty to a modest proportion proving themselves perennial. Of the hundreds of Chinese Primroses known to science the proportion at present in general cultivation is minute, and probably does not exceed three dozen. P. Florindae, the last and the largest, can hardly trouble any cultivator; nor can P. pulverulenta or P. integrifolia, which must be the oldest; P. Veitchii, P. Bulleyana, or P. Beesiana. P. Cockburniana is so easily renewed that its usually brief career is no stumbling block, and K. Ward's variety of it seems more perennial. The same may be said of P. chungensis. P. chionantha is sometimes a little more than biennial and is easily managed. P. microdonta and its fine varieties seem most obliging. Those who failed with P. Littoniana when it was first available should try it again, as one or two amateurs have succeeded with it. The same may be said of P. nutans, which Mr. C. T. Musgrave has not found to be calcifugal; it seems less fugitive than it used to be and is worth a deal of trouble. A colony of this species in bloom at Caerhays many years ago was one of the floral sights of a lifetime. P. Waltonii has yet to find its level, but promises well. P. vittata, P. Poissoni, P. pseudo-sikkimensis and P. secundiflora present no difficulty. P. Smithiana and P. helodoxa are content if their thirst is slaked; the latter was killed in many places last winter.

The photographs that illustrate these notes have been reproduced by the kind permission of the Royal Horticultural Society, Prof. W. Wright Smith, Mr. George Forrest and Dr. H. Handel-Mazzetti. *A. Grove.*

THE GENUS PRIMULA.

(Continued from p. 248).

MELANOPS (W. W. Sm.). Nigger P.
(Nivales.)

This sombrely-tinted, perennial species produces a tuft of broadly lance-shaped or oblong, pointed leaves gradually tapering to a winged stalk, in all from two to five inches long; margin edged with sharp, somewhat recurved teeth; upper surface smooth, underside coated with white meal. Flower stem four to six inches tall, bearing an umbel of six to fifteen fragrant, deep rich purple blossoms with almost black centres. Corolla about one inch across, more or less flat, with broadly-rounded lobes; tube cylindrical below, dilated upwards, about five-eighths-of-an-inch long. Flowers in June.

Grows in open or half shady spots on alpine slopes, in south-western Szechuan, at 14,000 feet to 15,000 feet above sea-level.

Culture: Good fibrous loam and peat, in a fairly damp, open spot, should suit it.

MELICHLORA Balf. f.). Honey-coloured P.
(Minutissimae.)

This dwarf, perennial plant, which is a micro-form or sub-species of P. spathulifolia, Craib., produces a tuft of oblong or narrowly elliptic, pointed leaves about one-and-a-half inch long, tapering to a broadly-winged stalk; margins furnished with sharp, regular teeth; upper surface somewhat glaucous and sparsely mealy, underside densely coated with yellow meal. Flower stalk mealy, bearing a solitary blossom, the colour of which has not been recorded. Corolla rather thick in substance, about five-eighths-of-an-inch across, with broad, cleft lobes; tube about half-an-inch long, cylindrical. Flowers in June and July.

This species is found near Tosa, in the Sikkim Himalayas, at 14,000 feet to 15,000 feet above sea-level.

Culture: Plant it in peat and light calcareous loam, in an open situation, if possible among very dwarf herbage, or grow it in a cold frame in a similar compost.

MEMBRANIFOLIA (Franch.). Filmy-leaved P.
(Farinosae.)

A beautiful, tufted perennial species with very thin, pale green, broadly oval or egg-shaped leaves from three-quarters-of-an-inch to two-and-a-quarter-inches long, tapering towards the base with unequally toothed or bi-serrate margins; upper surface more or less smooth, underside densely coated with sulphur-coloured meal. Flower stems slender, three-quarters-of-an-inch to two inches tall, coated with sulphur-coloured meal, bearing an umbel of four to nine soft violet-rose, slightly fragrant blossoms with a yellow eye. Corolla five-eighths to one-and-a-quarter inch across,slightly concave; lobes broadly heart-shaped, notched; tube funnel-shaped, greenish-yellow, two or three times as long as the calyx. Flowers from May to August. Introduced in 1908. (*Gard. Chron.*, Fig. 100, p. 207, 1911, Vol. L).

Grows in mossy clefts in wet limestone rocks, in shady places, with a northern exposure, on the Tali range, in Yunnan, western China, at 9,000 to 11,000 feet above sea-level.

Culture: Grow it in peat, leaf-soil and chopped Sphagnum-moss, in a cool, shady spot kept saturated with moisture when the plant is in growth; or plant it in a crack in a limestone rock, packed with similar compost.

MENZIESIANA (Balf. f.). Menzies P.
(Muscarioides.)

A very charming species from the alpine regions of the eastern Himalayas, with a spreading rosette of non-mealy leaves about one-and-a-half inch long, with elliptic blades about one inch long, rounded at the tip, abruptly or gradually tapering below into a winged stalk with an obscure sheath at its base; margins furnished with regular, blunt, rounded teeth frequently with a sharp point at the tip; both surfaces pale green and clothed with glandular hairs. Flower stem about three inches tall, glandular-downy, bearing a head of radiating, sub-reflexed blossoms about one inch across. Corolla about half-an-inch long, concave, narrow, deep blue or violet with a white eye; lobes egg-shaped, blunt, bifid, erect; tube cylindrical below, dilated upwards, about a quarter-of-an-inch long. In cultivation in 1915.

Grows in crevices and on ledges of cool, moist rocks, in shady places, usually with a northern exposure, in Bhutan, eastern Himalayas, at from 13,000 feet to 15,000 feet above sea-level.

Culture: Peat, loam and limestone chips in a very cool, damp spot facing north-west, with adequate protection from damp in winter, is indicated. *A. W. Darnell.*

(To be continued).

AN OLD GARDEN PRIMROSE.

Of our old-time favourites of the garden, many are now unknown; in these days of haste and bustle, types of really fine flowers that were studied, cultivated, and perfected in the last century are lost to view, their form and constitution unknown.

It may be that knowledge of their habits faded, or it may be that an insatiable desire for something new induced neglect of the floral gems of days gone by. The tendency is to look for something new, there is eager search for fresh floral forms and a desire to see points of merit, or fancied excellence, in novel varieties. Rarely do we note appreciation of, or even knowledge of the good, time-honoured, truly British flowers like the Polyanthus.

Men of science, taste and judgment are going back to the original species in order to raise new varieties, rather than cultivate and study the beautiful specimens handed down to us by florists of equal taste and judgment.

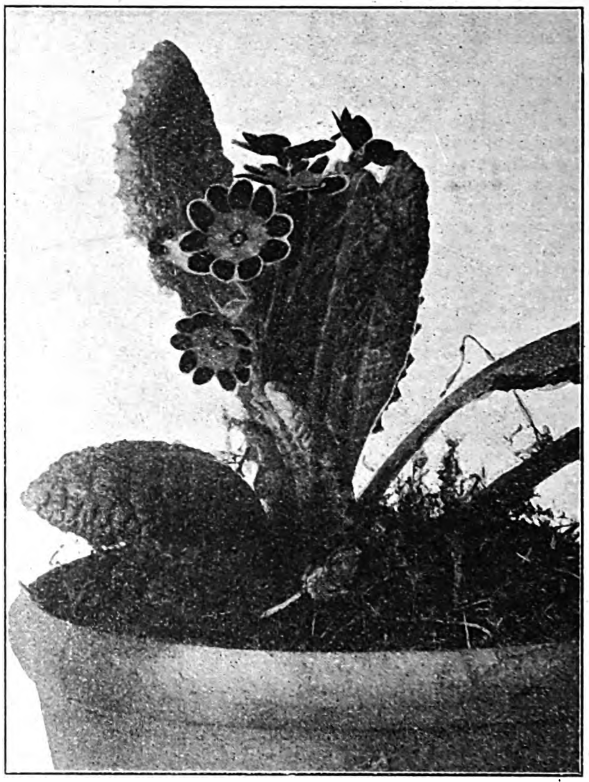

FIG. 138.—GOLD-LACED POLYANTHUS VAR. MRS. JOHN TONGE.

The old sorts seem to be "unwept, unhonoured and unsung." The assiduous quest for novelty is much more conspicuously in evidence than the knowledge of the old types and the appreciation of their qualities and properties.

Masses of bloom used for bold decorative effect are more studied than the characteristic excellence of individual flowers. Groups are insistent in their appeal to the many; the beauties of individual specimens need patience and observation—then comes appreciation, and taste is cultivated.

I here enter a plea for the consideration of a variety of "Prima Rosa"—the Polyanthus, and it is difficult to name any hardy flower which is so generally useful (as vigorous varieties are so easily raised); it is an early, sweet and pretty flower, not difficult to grow; in fact, its cultivation is simple as meadow grass; it is, perhaps, the earliest of hardy florists' flowers, and it will bear any amount of petting.

Its early season of flowering and its delicate perfume are points in its favour. It possesses a graceful elegance of form, a richness of colouring and symmetry of parts not to be found in any other flower.

Like the Auricula, it is so prettily divided at the edge that it appears to have five or six petals. The pip is perfectly flat and round, although slightly indented on the edge; the tube bright yellow, as also is the edging or lacing of the red body-colour, forming so many loops of gold encircling beads of velvety crimson or maroon, and giving the flower its jewelled appearance. Thus is the "Polyanthus" as described in 1750; other Polyanthuses are called "fancy ones," and "common ones." Old Worlidge said: "It is better to trust your eye than any description."

In general, Polyanthuses are not so much appreciated as they should be, considering the wonderful array of beauty they present; for rich and charming inlaid colouring they surpass all other flowers of our spring gardens. They are easily grown, fully fertile, and most prolific.

It is a common mistake to imagine that the florists' types of Polyanthus are delicate and difficult to grow, basing this idea on the facts that florists who are exhibitors carefully tend the special plants of their choice, feed them and protect them so that when placed on the show bench the blooms will be as perfect and as unspoilt as may be. Cultivation of plants for exhibition must necessarily be different from ordinary garden culture.

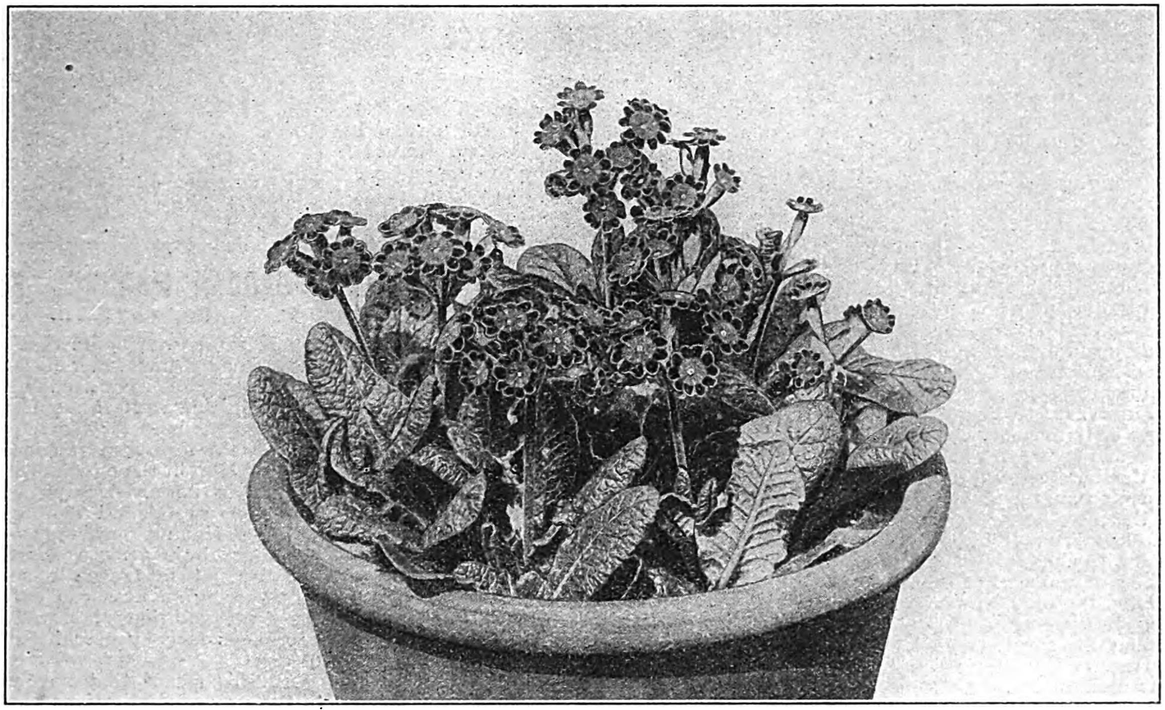

FIG. 139.—GOLD-LACED POLYANTHUS.

For the moment, I am not concerned with the merits of the flower as a show flower (Fig. 138), but with its utility and surpassing excellence over other forms as a bedding plant for brilliancy and decoration; "It will snatch a grace beyond the reach of art."

The highest type of Polyanthus is, if anything, hardier than the common, or fancy, types grown in the borders. A bed of gold-laced Polyanthuses has a distinction all its own. "Common sorts thrive in ordinary borders, there is no peculiarity changing the nature of those which are specially prized, they are possibly more robust than the commoner ones, and they grow stronger; there is no reason why the prized varieties should not be grown as well as the common sorts." (*Gardener and Practical Florist*, 1843.)

Probably the reason for the general disappearance of the old type is due to the habit of raising plants from seeds simply harvested from selected plants that bore some trace of gold lacing.

It would be unwise to recommend anyone to raise seedlings of gold-laced Polyanthuses from seeds bought at shops, except for the purpose of mere plant growing or for quantities to be planted as border flowers.

Select the plants when in bloom, grow them out-of-doors, shade them in summer, and let them have all possible sun in winter. Lift the selected plants about March, before they bloom, pot them and place them in a cool house, or under a bell-glass—with proper precautions. The flowers of these plants, if hand-fertilised, may be expected to yield seeds whence will come blooms of the desired kind (Fig. 139) in some proportion to the quantity of seeds sown.

From a garden miles away sixty plants were selected and planted in a spot very remote from other Polyanthus plants, a good harvest of seeds resulted. As the isolation of the plants had prevented cross pollenation, about forty per cent. of the plants raised from these seeds were true to type, and from the seeds of selected plants the following season I obtained seedlings of which over sixty per cent. were true; the discarded seedlings were mostly yellow ones.

On another occasion, I had from seeds saved from selected plants, a group of seedlings containing seventy-five per cent. true; the remaining rogues were yellow.

Hand fertilised seeds are, of course, surest, but must be secured with every precaution. A selected type should be saved and isolated for seed purposes. To expect seedlings to come true to the selected form when Polyanthuses of all sorts are grown all around is to expect the impossible, and is contrary to experience. Polyanthuses, Primroses, Oxlips and Cowslips hybridise very readily.

Five years ago, as a contrary experience, I raised six hundred or eight hundred plants from so called "gold-laced Polyanthus" seeds, obtained in the ordinary way of commerce from a reputable seedsman; alas! only a few of the resulting plants showed traces of gold lacing, and not one of the whole number was truly gold-laced; indeed, hardly ten per cent. had traces of gold lacing. Select the plants, isolate or hand fertilise the flowers, and sow the seeds in January; prick out the seedlings while small, giving them plenty of air and space; in this way one may establish a group of a few hundreds of a selected type—if it be the gold-laced type, that is so much to the good.

Strong, though not heavy, soil, well manured, suits Polyanthuses; the site should be sheltered from cold winds, but not deprived of air, as there is no plant that delights more in plenty of pure air. Let the plants be planted deeply where they receive all the winter sunshine and some shade in summer. Polyanthuses will not endure frequent applications of water over the foliage, as this seems to close up the pores and prevent proper respiration.

When planting, set the plants so deeply that the leaves are within half-an-inch of the soil, so that new roots, which are often produced from the "stem," may be able to enter the soil. When replanting, cut off the Carrot-like part of the stumpy root, retaining that part only which has plenty of fibre. Place the selected plants into pots about March, plunge the pots in cinders or ashes in the cool house, and see that there is a free circulation of air around the plants and the pots. Keep them moderately dry during November, December, January and February, but in March they may be mulched, removing one inch of soil, and top-dressing with rich compost. A good potting compost consists of one-third loamy soil, one-third very well-decayed manure and leaf-mould, and one-third coarse sand from river or sea—pit sand is dangerous. *C. W. N., Hale.*

ALPINE GARDEN.

PHLOX DOUGLASII.

The genus Phlox has given us many invaluable garden plants, both for the herbaceous border and the rock garden, among the latter none being more beautiful than the lovely Phlox Douglasii, from the eastern and western Rockies.

It is not by any means the easiest of them to grow, but, on the other hand, it is by no means difficult, if suitable growing conditions are provided for it. Perhaps it is best grown in the moraine, although it is almost equally at home on a moderately sunny ledge, provided it has a deep root-run in soil of a light, loamy nature in which an abundance of chips and small pieces of rock has been incorporated; a surface layer of chips will also prove beneficial in draining off the surface moisture in winter, this Phlox being impatient of dampness around its "collar." Moreover, P. Douglasii would appear to prefer slight shade from the hottest mid-day sun, therefore it should not be planted in a too open and exposed position; the cool base of a large, flanking rock is ideal. Under such conditions it will form a close mat and last for many years, its main branches taking on a gnarled appearance with age, all its short growths being densely clothed with small, narrow and hairy leaves. And then, in June, this close mat of foliage becomes transformed by the numerous beautiful, closely-set flowers into a carpet of lilac colouring, clear and bright in its intensity and extremely attractive.

But P. Douglasii would appear to have one failing, shared by many choice subjects, namely, that of dying-off suddenly, sometimes even when at the height of its glory and in full flower. Therefore it is wise always to have a good stock of plants in hand to meet such emergencies, for the alpine garden should never be without so beautiful a plant. And this is not difficult, for P. Douglasii may be propagated by cuttings of the young, fresh growths, taken with heels in early summer, their lower leaves carefully removed, and inserted in a bed of sand in a cold frame or under a bell-glass. Provided care is exercised in watering the majority of them should root, and although not quick-growing in later life, the young plants should soon make nice little specimens for planting out.

THLASPI ROTUNDIFOLIA.

It is not often that Thlaspi rotundifolia—the Iberidella—is obtainable, and when, at last, it is secured and planted in the rock garden, it seldom survives more than one or two seasons, usually because flowers are produced so prolifically that it exhausts itself and is unable to survive the rigours of winter. But T. rotundifolia is a singularly charming subject, even although the colour of its flowers may not appeal to all plant lovers. It forms a small tuft of little, fleshy, waxy leaves, oval in shape and smooth, and above these, in almost shameful profusion, are borne during summer large, flattened clusters of flowers, of good size, fragrant with the perfume of honey, and of rosy-lavender colouring, but with that illusive bluish tint which, in the eyes of some, detracts from its beauty, although it is not present when the blooms are freshly open. All this, provided it is afforded the conditions essential to its well-being, for if its requirements are not carefully attended to it is almost sure to languish and perish without giving of its beauty.

P. rotundifolia is a sun-lover, and hails from the highest screes of the limestone and sandstone alps of Europe. Therefore, in the alpine garden it is best grown in the moraine, or in a sunny position, in deep, loamy, well-drained soil abundantly supplied with limestone chips and small pieces of rock to ensure perfect drainage and to allow its long tap-root to penetrate deeply. A covering of a pane of glass may prove of use in assisting it to survive the winter. In a warm, sunny season it will ripen seeds which should be secured and sown. *Kent.*

FLOWER GARDEN.

SUNBEAM POPPIES.

These improved Iceland Poppies (natives of Siberia and North America) attracted a good deal of notice when they were first shown at Chelsea a dozen or so years ago, the combination of size and glowing colour being very striking. But many did not succeed with them well enough to try a second or third time, and there is no denying that unless grown very well indeed they are not very satisfactory. They are often to be seen with small flowers on long, wiry stems, bent or crooked. Sown in the open ground in the spring, or even raised under glass early and planted out, they are rarely satisfactory.

The only way to get fine blooms is to sow the seeds in the first half of July, a bad time for sowing seeds, for under glass the seedlings get drawn up if shaded, and scorched if exposed to the sun, and in the open they may be washed away by a thunderstorm; a moist nursery bed in partial shade offers the best chance. The seedlings should be thinned early, if necessary, as legginess is fatal, and so soon as they are large enough they should be pricked out in boxes and put in a shaded frame until established, and later, probably the latter part of August, potted into sixties and grouped in a sunny place in the open. They are not completely hardy at this stage, for 10° of frost may kill the outer leaves and weaken the plants permanently, while a further 5° may kill them outright; so that after the end of October they are safer in a frame. Early in the year, a bed should be prepared for them in a sunny site where they will receive some shelter from the worst of the wind. They need good soil, deeply worked, and so soon after February as conditions permit the plants should be put out one-and-a-half foot apart. The bed will look very thin at first, but they make surprisingly large plants if they have room and good feeding, and it is only from such plants that those large flowers with firm, straight stems, so much prized for cutting, are obtained. They should begin to flower by the middle of May, and will be getting untidy about midsummer, when some summer bedding plants should be ready for succession. The alternative is to grow them in a reserve garden or nursery border solely for cutting, when they may be cleared away in time for other sowings or for seedlings. They are called perennials, but, in most districts, very few survive to bloom twice, therefore it is better to rely upon first-year plants. *A. Petts.*

HOME CORRESPONDENCE.

Ivy Baskets.—Realising how much more his interest is centred in worms than snails, I can quite understand that the Rev. Hilderic Friend did not recommend Ivy for the purpose *H. E. D.* (p. 188) desires. To my mind, it is only he who wishes to study snails in their many aspects who should cherish the Ivy basket. On two occasions it has been my ill-fortune to succeed to some of these relics of a by-gone gardening taste. On the first occasion I, being young and full of artistic endeavours, visualised most entrancing floral effects with growing plants in such ideal frames. But after two seasons I gave up the unequal contest with the untold snails, and reluctantly dispensed with my Ivy baskets and the artistic ambitions associated therewith. Later, I again inherited some of these unparalleled snail resorts. With my enthusiastic youth had gone many illusions, and with them my ideas of the possibilities of the Ivy basket in the scheme of garden decoration, but I had acquired a certain amount of stubbornness of spirit, and determined, snails notwithstanding, to have beautiful flowers in baskets of growing Ivy. But again, I reckoned without my host— . . . of snails —and, after a season of struggle, gave up my hopes and the Ivy baskets. Curiously enough, while thrushes will diligently search along the foot of an Ivy-clad wall for snails, I never saw one investigate these Ivy baskets. *A. C. B.*

Frost Injury to Trees.—The account by Mr. T. Wallace in *The Gardeners' Chronicle* of March 16 (p. 209) of the injury by frosts to some of the Apple trees at Long Ashton, is especially valuable in the data which is given, and I feel sure many readers would welcome, in due course, particulars of the after behaviour of the affected trees. While I cannot recall having seen any instance of similar injury to a fruit tree which might be attributed to frost, I have on several occasions been shown cracks, somewhat similar to that illustrated on p. 210, in the trunks of other deciduous trees. Curiously enough, in each case the injury was attributed to lightning—an explanation of the injuries which I did not accept. As Mr. Wallace evidently realises, injury to trees from winter frosts may well continue undetected for a considerable time, and so frost was not suspected in the instances I have in mind. When a boy, at home in Exeter, I well remember, during a spell of very severe frosts, my father protesting that "now-a-days we do not know what cold weather really is." This was when the swift-flowing river Exe was frozen! He went on to cite a winter of his early manhood when "night after night the thermometer went down well below zero, and in the small hours you could hear the trunks of big trees cracking with reports like those of great guns." Unfortunately, I am not able to give any exact data, but it must have been a winter of the "middle sixties." *A. C. B.*

Old Chelsea Nurseries.— I was very gratified that my little note on the Lapagerias in the great corridor at Veitch's nurseries in King's Road, Chelsea, fifty years ago, brought responses from three old Veitchites. I beg to be allowed to send greetings to them, and to express the hope that they are still as full of zest and activity as, happily, I am myself. I well remember the early "stalwarts" at Veitch's, with John Dominy as first hybridiser. Two famous later raisers—Seden and Heal—doubtless learned their job from him or through his influence. Minns was a great grower of hard-wooded plants, and Tivey of Nepenthes, etc. Then there was dear old George Schneider, whose *Book of Choice Ferns*, published so far back as 1892, still stands on my shelves as a reminder of one of the kindest friends of my boyhood. How I loved to listen to his tales of the battles of the Franco-Prussian war of 1870, through some of the fiercest of which he passed! But there were two other large nurseries quite near Veitch's fifty years ago. At the head of one was William Bull, whose displays of Orchids in his own nursery were features of the season. The other was Wimsett's, which pursued a decorative trade on a large scale. Of course, Chelsea knew older nurseries still, and I often think that an interesting book might be written on these and other famous nurseries of London. I, for one, should read it with avidity, but I fear that it could not compete in popular favour with murder mysteries, which now seem all the rage! Murder mysteries, forsooth! Why not Chromosomes? *W. P. W.*

GARDEN MANURES FOR APRIL.

The grower who hopes that there is a short-cut method of improving his land by an application of highly concentrated fertilisers, is doomed to disappointment, if he has not previously prepared his land for the reception of the fertiliser. As has been previously pointed out, the first step in the enrichment of unproductive land is to improve its physical condition by means of careful and thorough tillage, by the addition of humus-forming material and perhaps by under-drainage. In short, the soil must first be put into such mechanical condition that rooting systems can extend in it; after that, the addition of chemical manures may pay handsomely by returning an increased weight of crop.

All this means that no amount of penance in the way of applications to the land can ever atone for the sins of poor tillage. A system of manuring for cultivated orchards may thus be based on the provision of organic manure at least every two or three years; the addition of lime every three or four years to aid in the decomposition of vegetable matter, and to maintain a sufficiency of lime as plant food; and, finally, to maintain an abundance of all forms of available plant foods at the times needed for the development of the tree and fruit, annual applications of chemical fertilisers may be made.

The first two would naturally be applied during the dormant season, but the latter would be applied during the active growing season, and could be used in the proportion of one hundredweight of sulphate of ammonia to three hundredweights of superphosphate and to two hundred-weights of muriate or sulphate of potash. The actual amounts to be applied naturally depend on the character of the soil, the kind of fruit, and the age and vigour of the tree, but these, amounts may be taken as a minimum, and in old-established orchards of bearing trees much larger applications may be given with good results, moreover, the proportions may also be varied to meet particular needs. It may not be always necessary to apply a nitrogenous manure, but in this respect the amount of growth and the colour of the foliage are reliable guides as to the need of nitrogen. When mature or bearing trees make a foot or more of growth on all shoots, and when the leaves are of full size and dark colour, it may be assumed that the orchard has enough nitrogen for current needs, therefore, a free application of a nitrogenous fertiliser might do more harm than good by promoting growth at the expense of fruits.

Nitrogen-fertilising exerts, further, a decided influence in delaying the maturity of fruits, and it is worth while to consider its effect in this direction, for, while the application of such fertilisers to late Apples which tend to ripen too early, might result in profit, their application to early maturing varieties might lead to loss by causing delay in marketing. On many soils also it is better to supply nitrogen by good cultivation—which assists nitrification—and an occasional green manure crop where this is practicable, than by the application of chemical nitrogenous fertilisers.

Even when trees are not growing satisfactorily. and appear yellowish in foliage, good cultivation, begun early and continued frequently, with the use of potassic and phosphatic manures, will frequently correct it. When trees fail to respond to ordinary treatment, however, a dressing of nitrogenous manure may quickly restore them to health and vigour.

In general, phosphoric acid is probably less important in fruit plantations than potash, but the grower should remember that the plants need all the elements of plant growth and that a soil deficient in phosphoric acid cannot give maximum results until this deficiency is made good. Probably the best means of applying phosphoric acid is by superphosphate or a mixture of superphosphate and finely-ground bone-meal, the latter giving also a percentage of nitrogen, and adding to the lasting properties of the dressing. The present month is a good time for the application of such fertilisers.

The fruit-grower will naturally ask how he is to tell just what kind and what quantity of fertilisers he should apply to his land. This is one of those questions which no one can answer for him in detail. Having studied the matter carefully and observed his trees from day to day and year to year, he should be able to discover the treatment which they need. A fruit plantation which is giving wholly satisfactory results demands nothing more than a continuance of the treatment which has brought about those results, but unsatisfactory yields denote that some change in the management should be made, and in many cases quick and relatively cheap results may be obtained by the use of quick-acting chemical fertilisers during the active season of growth. *W. Auton.*

RABBIT DAMAGE TO FRUIT TREES.

The damage done to the trunks of fruit trees, particularly young trees, by rabbits and hares is familiar to most people, but it is seldom that one hears of rabbits climbing trees to feed upon the branches.

In an Apple orchard near East Malling a large number of trees have been attacked by rabbits in this way. The trunks are all protected by wire-netting to a height of about two feet, and it would seem that the rabbits climbed the netting, perched in the crutch of the trees, and gnawed the bark of the branches within reach. Indeed, they must also have climbed fairly slender branches, for it was common to find the branches gnawed at a height of four feet above the ground. Many of the spurs were completely girdled or bitten off, both in the crutch of the tree, and on the branches up to a height of four feet. Some of the more slender branches were also girdled, but usually the upper surface only was eaten. It was common to find branches two inches or more in diameter of which the whole of the bark had been removed along one side for a distance of eighteen inches or so.

The illustration (Fig.140) shows a rather small tree, with branches gnawed to a height of four feet above the ground. Although this was one of the most badly damaged, a great many other trees were attacked to almost the same extent.

When first noticed, it was thought that the damage might be due to rats, but closer examination showed that rabbits were responsible. Their droppings could be seen on the ground under damaged boughs and branches, their teeth marks could be plainly seen in the wood from which the bark had been removed, and certain scratchings abundant on the upper surfaces of some of the branches were obviously caused by rabbits' claws. Presumably the rigours of the frosts of February and March had made the animals very hungry, and so led to this enterprising method of obtaining food. *W. Steer, East Malling Research Station.*

PUBLIC PARKS AND GARDENS.

A recommendation to the Cardiff Town Council to purchase Gillard's Field, at Virgil Street School, for conversion into a public recreation ground for Grangetown has been approved.

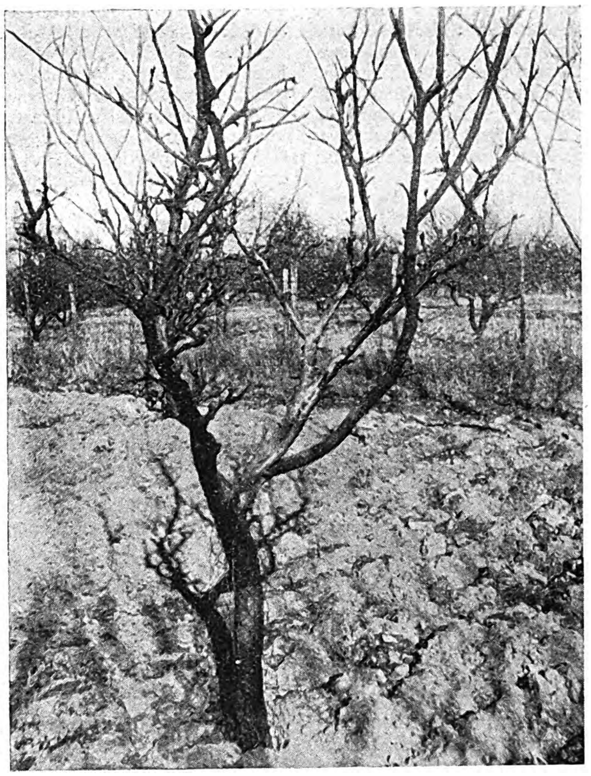

FIG. 140.—APPLE TREE DAMAGED BY RABBITS.

The branches were gnawed to a height of four feet from the ground, the inner surfaces of the branches being damaged as badly as the outer.

At a cost of £1,029, the Crewe Town Council is to level and surface land off New Street for a children's playground.

The Bideford Town Council is recommended to approve a scheme for the lay-out of the Old Town Boys' School site. This includes a shelter, rockery and flower garden at an estimated cost of £430.

The Windsor Town Council has received the title deeds of a six-acre site at Clewer, which is being presented to the town as an open space in perpetuity by Mr. Arthur Stovell and Captain Lionel Stovell.

The Erith Urban District Council has received the sanction of the Board of Education to plans for the lay-out of the Brook Street site as a playing field.

The Kircaldy Town Council has under consideration a proposal to provide public bowling greens in the Beveridge Park and the Third Ward, at estimated costs of £1,750 and £2,900.

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting of this Society, held on March 1, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, J. Evans, A. Keeling, D. McLeod and H. Arthur (Secretary).

First Class Certificates.

Cymbidium Alexanderii var. Evansiae.—Large, well-shaped flower, slightly flushed; lip with dark crimson marking. *Cypripedium Gwen Hanmer var. album.*—Large, white dorsal sepal and yellowish-brown pouch. Both from Mr. J. Evans.

Sophro-Laelio-Cattleya Margrand var. Tangerine (S.-L.-C. Marathon × *S. grandiflora).*—A large flower of the type, of brilliant colouring. From Mrs. Bruce and Miss Wrigley.

Award of Merit.

Cypripedium Aureades var. Whitecap.—From Messrs. A. J. Keeling and Sons.

Groups.

Messrs. A. J. Keeling and Sons, Bradford, staged Cypripedium Pyramus var. magnificum, C. Porthos, C. Alcivana and several seedlings, together with Epidendrum Endresii, and Dendrobium Lady Colman.

Mr. John Evans, Colwyn Bay, staged Cypripedium Memoria var. J. H. Walker.

At the meeting held on March 15, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, J. Evans, A. Keeling, D. McLeod, W. J. Morgan and H. Arthur (Secretary).

Awards of Merit.

Cypripedium Huglii (C. Pyramus × *C. Elise II, Keeling's var.)*; *Cypripedium Volga (C. Zaria* × *C. Cardinal Mercier)*, and *Cypripedium Amazon (C. Memoria F. M. Ogilvie var. Rex* × *C. Perseus)*.—From Captain W. Horridge.

Lycaste Skinneri, Wivelsfield var., and *Odonto-*

glossum venustulum, Wivelsfield var. From J. Ingham, Esq.

Odontioda Colinge var. Evansiae and *Dendrobium Gatton Monarch.* From Mr. J. Evans.

Odontoglossum Pescatorei var. Peachblossom, and *O. Meredithiae* (*O. Rossi* × *O. venustulum*). From Messrs. A. J. Keeling and Sons.

Cultural Certificates.

To Mr. J. Howes, for Dendrobium Wardianum and Sophronitis grandiflora.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged a group to which a Large Silver-Gilt Medal was awarded. It included Odontoglossum Theresa var. lilacina, O. Chanticler, O. Leeanum, O. Bonar Law, O. Coronation, and O. West Point Beauty; Odontioda Colinge var. Ruth; Cypripedium Boltonii, C. The Major, C. Conference, C. Golden Glory and C. Ernest Reid; Platyclinis glumacea; Oncidium splendidum and others.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, were awarded a Large Silver Medal for a fine group containing Lycaste Skinneri var. Sentinel, L. Claret, L. Modesty, L.Goliath, L. alba var. Pearl, L. lasioglossa and L. Tunstillii; Dendrobium Apollo var. album, D. Cybele var. album, D. Rolfeae var. roseum, D. melanodiscus var. Luna, and D. Euryades var. Painted Lady; Vuylstekeara ignescens and Cymbidium Pauwelsii var. Beige, with Cypripediums in variety.

J. Ingham, Esq., Gee Cross, Hyde, was awarded a Large Silver Medal for a collection containing Odontoglossum Lambeauianum var. Mikado, O. rubens and O. Gloriana; Odontioda Gloss; Dendrobium nobile, Berkeley's var.; and Cypripedium Olympus var. The Chairman, C. Vashtii, C. Imperator and several seedlings.

Captain W. Horridge (gr. Mr. Coningsby), Bury, staged Dendrobium Merlin, Boltholt var., D. aureum, D. Lady Colman and D. King George.

Mr. John Evans, Colwyn Bay, staged Miltonia St. André, Cymbidium Devonianum and Cypripedium Enchantress; while Messrs. A. J. Keeling and Sons, Bradford, staged Oncidium superbiens, Cypripedium Charlotte Dillon, and Dendrobium Renown.

The next meetings of this Society will be held on Thursday, April 18, at the Town Hall, Manchester, in conjunction with the Spring Show of the Royal Botanical and Horticultural Society of Manchester and Northern Counties.

SALISBURY GARDENERS'.

The final meeting of the above Society for this session took place in the Lecture Room of the White Hart Hotel, on Wednesday evening, March 20. In the absence of Mr. S. W. Tucker, through illness, Mr. A. E. Davis occupied the chair, and was supported by Mr. P. Baglin, Hon. Treasurer, and Mr. W. F. Gullick, Hon. Secretary, and other officers of the Society. Previous to the Chairman introducing the lecturer, Mr. C. J. Phelps stated that, on behalf of the Society, he would like to convey their congratulations to their Hon. Secretary, Mr. W. F. Gullick, on the recent honour accorded him in being unanimously elected President of the local Chamber of Commerce. This announcement was received with much applause, to which Mr. Gullick suitably responded.

The Chairman welcomed the lecturer, Mr. C. Haysom, of Mr. Dalrymple's nurseries, who had come to talk to them on Freesias. He also extended a hearty welcome to members of the Romsey Gardeners' Society, of which Mr. C. Haysom was a member. A large and appreciative audience listened to the fascinating history of the Freesia, from the time when the first species was introduced under the name of Gladiolus refracta, down to the present wonderfully coloured hybrids, a beautiful selection of which was exhibited by the lecturer. In his opening remarks, he stated that it was not until 1830 that Freesias were classified as such, at which time only three species were known—F. refracta var. alba, F. aurea and F. Armstrongii. One of the first hybrids was secured by Mr. Chapman, of Rye, by crossing F. aurea with F. Armstrongii, which produced the variety Chapmanii. Proceeding, the lecturer stated that in 1914 Mr. Dalrymple became particularly interested in Freesias, and purchased the collection of the late Rev. W. Jacob, and in April, 1918, he exhibited before the Royal Horticultural Society seven coloured hybrids, and gained three awards for them. The first coloured hybrids, however—Canary, Buttercup and Apogee—were raised by M. van Tubergen, and put on the market about 1918.

Valuable hints were given relative to their cultivation, the chief essential being light, sandy soil and sharp drainage. He recommended five-inch Long Tom pots, planting five to eight corms in each. Any fertiliser used should be given in liquid form, and never as a powder. He mentioned that in his opinion the ripening process was the most important. It was essential that the corms be baked, by placing them on a shelf in the hottest part of the greenhouse and covering the box with brown paper so that the direct rays of the sun did not scorch the bulbs.

Mr. Hammond, in proposing a vote of thanks to the lecturer, mentioned that although they had had some wonderful lectures during the session, he felt that "the best wine had been kept until last." Not only did the Society greatly appreciate the valuable information that the lecturer had imparted, but they were very grateful to Mr. Dalrymple for having made the lecture possible. The proposal having been seconded by Mr. Asher, it was carried with acclamation.

Before closing, Mr. W. F. Gullick stated that arrangements were being made for the Society's Annual Outing, to take place in July, when they hoped to visit the gardens and grounds of Littlecote, Hungerford, the seat of Sir Ernest Salter Wills. They also hoped to pay a visit, one evening, to Clarendon Park.

The thanks of the Society to the Hon. Secretary and Hon. Treasurer were proposed by Mr. H. M. Barry, seconded by Mr. A. E. Davis. In addition to the wonderful selection of coloured hybrids, exhibited by Mr. Haysom, a well-grown specimen of Freesia Treasure was on view from Mr. C. Dredge, Downton, and a remarkable new hybrid Azalea indica, from Mr. W. F. Gullick.

KILMARNOCK SPRING SHOW.

The seventh Annual Exhibition of Tulips, Hyacinths and Daffodils, promoted by the Glenfield and Kennedy Horticultural Society, was held at Kilmarnock on March 23, when the entries, which numbered over 500, constituted a new high record. There were seventy classes in the open and confined sections, and competition was keen, especially in the classes for white Hyacinths, early single Tulips, and King Alfred, Spring Glory, Sir Watkin and Lucifer varieties of Narcissus. Notwithstanding the prevalence over a long period of low night temperatures there was a conspicuous uniformity in the high quality of the blooms, which compared favourably with that of previous years.

The principal awards in the open classes were as follows:—The John Craig Challenge Cup, for Tulips, in the open section, to Mr. John Cochrane; the Crawford Challenge Cup and Silver Medal to the most successful competitor in the Daffodil open section, to Mr. James Cochrane; the special prize for twelve cut blooms of long Trumpet Daffodils, to Mr. James Dodds. In the confined section, the Ferguson Hyacinth Cup and the Mrs. Bruce Ball Tulip Cup were both awarded to Mr. Charles Barclay, while Mr. James Currie excelled in the Daffodil section and secured the Mrs. Jane Kennedy Cup. The achievement of the latter competitor is all the more creditable when it is explained that all his exhibits were grown in the windows of his dwelling house. The best pot of Tulips in the show were exhibited by Mr. James Watson (variety Prince of Austria); the best Hyacinths by Mr. D. E. Drummond variety White Friar); and the best Daffodils by Mr. James Dodds (variety Van Waveren's Giant).

Obituary.

Richard Cobley.—In spite of his eighty-four years, Mr. Richard Cobley, of Walnut Tree House, Cheshunt, was hale and hearty up to about ten days before his death, which occurred on Tuesday, March 26. Mr. Cobley was a farmer during the early part of his life, but about forty years ago he began to build glasshouses and gradually gave up farming for market gardening. He was a very successful cultivator, and soon had a compact establishment of about fifteen acres. Later, he built another nursery, covering about ten acres. His three sons are well-known in the horticultural world—Mr. George Cobley, the accountant, of Southampton Street, Covent Garden; Mr. R. Seymour Cobley, a large grower of Daffodils and Tulips and intimately associated in business with Mr. George Monro (a nephew of Mr. Richard Cobley); and Mr. J. Cobley, who carries on the market gardening traditions and business at Cheshunt. Mr. Richard Cobley was very highly respected and honoured as one of the pioneers of the great commercial horticultural settlement in the Cheshunt district.

ANSWERS TO CORRESPONDENTS.

Construction of a Hard Tennis Court.—*A. R.* For a red hard tennis court, sixty feet by one-hundred-and-twenty feet, assuming the site is fairly level, excavate to a depth of nine inches. If the sub-soil is of a clayey nature, lay three-inch land drains at fourteen feet centres with a fall of six inches running north and south, connect these to a four-inch land drain with a fall of three inches running east and west to the lowest point. Lay the first line of three-inch drains two feet in from where the stop net fencing will be erected, *i.e.*, two feet, fourteen feet, fourteen feet, fourteen feet, two feet. Fill in to a depth of six inches with broken bricks, rough clinkers or other similar material, consolidate with a heavy roller, and then add two to three inches of fine ash, which, if dry, should be watered well, and consolidate it. Make up any weak parts with fine ash before commencing topping. Finish it with a two-inch layer of fine, screened red rubble, put on in three layers of one inch, three-quarter-inch and a quarter-inch, each layer being well watered and rolled. The court will then be ready for permanent marking. The approximate cost of this type of court, assuming the materials are conveniently situated and within reasonable carting distance, including fencing, posts and nets, and lead markings, is £130. These dimensions and quantities may be adjusted to suit circumstances.

Cutting Back Privet; Sowing Pea Seeds, etc.—*H. P. C.* No harm should accrue if you cut back your Privet bushes as you suggest. You should get quite good results from both Sweet Peas and culinary Peas if the trenches are made now; whether you use artificial or organic manure it should be well mixed with the soil. It is not too late to plant Rose bushes, provided they are tended carefully with regard to watering and mulching later; six good free-flowering sorts are Shot Silk, Betty Uprichard, Lady Inchiquin, Los Angeles, Mabel Morse, and Caroline Testout; Frau Karl Druschki, the best white, should, of course, be included.

Primrose Foliage Unhealthy.—*E. H. G. S.* The foliage of the double Primroses is suffering from a severe attack of mould, due to the fungus Ramularia primulae. Spray with Bordeaux mixture or, better, dust with dry Bordeaux ("Cupryl" Dry Spray of Craven's, Evesham), so that both surfaces of the foliage are covered by the fungicide. The foliage must be dry prior to spraying and slightly moist if a dust is used.

Royal Horticultural Society's Accounts for 1928.

Interest in the review (p. 195) of the salient points of the Royal Horticultural Society's accounts for 1928 will have been stimulated by the letter (p. 249) from Sir W. Lawrence, the late treasurer of the Society, which will be read by many as his *apologia*. The late treasurer protests that neither he nor his immediate successor is a chartered accountant, and, no doubt with the approval of his successor, makes the naive confession that each of them has been overshadowed by what he terms the Fowler-Reader-Harper complex, which, to old Fellows of the Society, is another name for the Wilks tradition. It is no disrespect to the memory of the man who salved the Society and laid the foundation of its present prosperity to state that the tradition in question was based on the principle that in matters of administration and finance the general body of Fellows were to be regarded as children and told only what it was considered good for them to know. In the hands of a genial autocrat like the late Rev. W. Wilks, the method worked, on the whole, successfully, because, as even those who did not always agree with his methods were the first to admit, he placed the interests of the Society before all else; but it had begun to crumble before the weight of years made it necessary for the saviour of the Society to lay down the reins. Once he was out of office, history repeated itself, and the *regime* he initiated became unworkable. But established customs die hard, and for reasons which are well understood by old Fellows and probably do not interest the younger ones, the Wilks tradition has yielded slowly and stubbornly to time, to death, and to the inexorable law that institutions like the R.H.S. must either move with the times or go under. Meanwhile, the tradition has hampered the administration of the Society, and not only in the department of finance to which the late treasurer refers in his letter. The fact seems to be that some of those Fellows who have grown up with it and have generously helped in its administration, have sometimes found it difficult to realise that the R.H.S. is no longer the comparatively unimportant, semi-private Society controlled by an astute and far-seeing director with the co-operation of a body of sympathetic councillors who seldom found it necessary to disagree with him. Thanks to the interest evinced in horticulture by the rising generation and the increasing tendency of the times towards publicity, the Society has now become a public body of considerable importance, in which the methods of administration so successfully pursued by the Rev. W. Wilks and those associated with him are totally out of place. One of the responsibilities of such bodies is the presentation of fully detailed accounts in such intelligible form that the "simple souls," who, according to Sir W. Lawrence, write their receipts and expenses on two sides of penny account books, may understand them. It cannot fairly be stated of the accounts as they are presented to the Fellows now, that they are beyond the understanding of men of average intelligence; but they might well be amplified, and when a late treasurer publicly confesses that the most serious disadvantage of the accounts in their present form is the impossibility of obtaining much information out of them, Fellows who are at all interested in the Society may well feel that the sooner the necessary adjustments are made the better. Sir W. Lawrence's suggestion that the Wisley accounts require elaboration is certainly shared by other Fellows, and in the absence of the necessary details to which, as subscribers, they are entitled, Sir W. Lawrence will not be surprised if his view that the Fellows get a good return for the money spent at Wisley, fails to meet with general acceptance. There are many who consider that the return from the ever increasing outlay on Wisley is comparatively meagre, and if Sir W. Lawrence is correct, the reason for this belief is to be sought in the nebulous character of the accounts and their want of detail. This is so far true that there is no mention in the accounts, for instance, of the expense of maintaining the School of Horticulture, nor are details about the School furnished in the annual report. Again, the accounts may be scrutinised in vain for any item relating to the distribution of seeds and plants to Fellows, or as to the cost of the various fruit, flower, plant and vegetable trials. There are few societies which can permanently bear an ever-increasing financial dead weight such as the R.H.S. has imposed on itself at Wisley, and the Council will not be surprised if many intelligent and loyal Fellows of the Society view the constantly increasing outlay with apprehension. The financial policy at present in force in relation to Wisley has only to be carried to its logical conclusion and the day must come—five, ten or twenty years hence—when the President will find it necessary to announce to the Fellows that the capital expenditure on the Gardens has reached a point beyond which it is inexpedient to go; by that time it may amount to hundreds of thousands of pounds! It is not always remembered that only a fraction of the total expenditure on Wisley is represented by tangible assets. The land is worth comparatively little; the buildings would go for what they would fetch, and the place is of value only so long as the Society pays the bill. As matters are at present, Wisley is the last stronghold of the Wilks tradition, and the sooner Fellows receive fuller information concerning the finances and the general management of the Gardens, the better for the Society and for horticulture in general.

H.R.H. the Prince of Wales and the Linnean Society.—His Royal Highness the Prince of Wales has graciously consented to become an Honorary Member of the Linnean Society of London.

Mote Cricket Ground, Maidstone.—Following the decision of the Maidstone Corporation to purchase Mote Park, which comprises some five hundred acres, for the nominal sum of £50,000, Lord Bearsted has intimated his intention of presenting the Mote Cricket Ground, together with some twenty acres surrounding it, to the Mote Cricket Club, on condition that it will be preserved for the purpose of cricket in perpetuity. The cricket ground, which has a handsome pavilion, erected by the late Lord Bearsted, is to be vested in trustees on behalf of the Mote Club.

The Weather in March.—The lack of rain, together with the unusual temperatures experienced in March, are emphasised by a perusal of the weather records taken at Crow's Nest Park, Dewsbury. At this station only ·31-of-an-inch of rain was recorded for the month. Of the thirty-one days, nineteen were completely rainless, and on three days there were merely slight traces of rain, not sufficient for measurement. The highest temperature recorded was on March 29, when the Fahrenheit thermometer registered 77°, while on six different days, the 10th, 11th, 27th, 28th, 29th and 30th, the thermometer registered 70° or over. The lowest minimum temperatures were recorded on the 1st, 2nd, 4th, 6th, 16th and 17th, the temperatures being 21°, 28°, 26°, 27°, 26° and 26° respectively.

Dutch Elm Disease.—The story of the Dutch Elm Disease, already given in these pages (February 9, 1929, p. 91), is now issued in pamphlet form as Leaflet No. 19 by the Forestry Commission. The leaflet is well illustrated, and can be obtained from the Forestry Commission, 22, Grosvenor Gardens, S.W.1.

The Studley College Flower Show.—We learn that arrangements for the flower show in aid of Studley College, to be held in the New Hall of the R.H.S., on April 24, are proceeding apace, and many leading trade exhibitors have agreed to stage groups, and have also consented to the sale of their produce after the show in aid of the Appeal Fund. Her Royal Highness, Princess Mary, will open the show, and as a practical expression of her sympathy with the movement has undertaken to send a contribution of flowers from Goldsborough Hall. The Organising Committee appeals to horticulturists in general to assist by sending gifts of flowers, fruits, vegetables and dairy produce, and to stage exhibits at this show.

Legacies to Gardeners.—The late Mr. Robert Ward, of Oaklawn, Leatherhead, who died on November 6, 1928, left £100 to his head gardener, Mr. George Buckland, senior.—The late Captain Sir Edmund Charles Nugent, Bt., of West Harding Hall, Norfolk, who died on December 4, 1928, left £100 to his gardener, Mr. Arthur Wiggett.

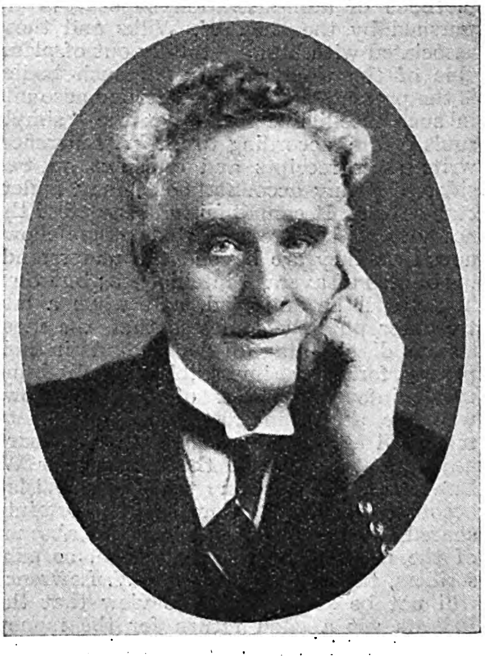
British-grown Bulbs for British Gardens.—Several years ago certain members of the British Florists' Federation presented large numbers of Tulip bulbs to the London parks, with the proviso that when these flowered they should be labelled to show they were entirely of British growth. How far this benefited the trade it is difficult to state, but the Dutch growers were not slow to take advantage of a similar opportunity to advertise Dutch-grown bulbs. Now the Empire Marketing Board is using "Home Bulbs for Home Gardens" as its spring slogan. The series of posters now on view in the Board's special poster frames depict the Daffodil farms of Cornwall and the Scilly Islands, and the Tulip fields of East Anglia, while gardeners are informed that "British bulbs give the earliest blooms." These large and attractive posters are the work of Mr. A. A. Moore, and the separate studies of Daffodils, Narcissi and Tulips, of Miss Irene Fawkes. The Board's interest in the Home Bulb Trade, however, is by no means confined to poster advertising. This will be the second year in succession in which Londoners will have an opportunity of admiring an all-British display of Tulips in the London parks, and again the cost will be shared by the Empire Marketing Board and the Office of Works. This season a similar exhibition has also been arranged in Edinburgh. It remains for bulb dealers to take full advantage of the work of the Empire Marketing Board, by advertising their British bulbs in due course. At the moment, the Board's posters form a good advertisement for the cut flower trade; had the colourful display appeared in August and September it would have proved a better advertisement for bulbs.

Afforesting Sandy Wastes.—Remarkable progress is being made by the Forestry Commissioners in the herculean task they have undertaken in afforesting the famous desert of the Culbin Sands and the great sand wastes in the vicinity of Burghead, on the Morayshire coast. The latter area was acquired in November last from the proprietor, Mr. G. R. McKessack, of Ardgye. Here, Mr. William MacKay, from the Beaufort Forestry School, Ross-shire, is in charge, and he is extremly hopeful of the task he has undertaken. This year he anticipates planting about one hundred acres with 2,000,000 trees, and to complete the whole job within thirteen years at the rate of fifty acres a year. The total area is 1,350 acres. Of this about 750 acres near the coast are to be surface-fixed by Marram grass, used so successfully in stabilising the dunes on the Culbin Sands. The grass creates a fine barrier to the advance of the sand along the coast. The remaining six hundred acres, on which work has now begun, is to be planted with Scots Pine and Corsican Pine. The work on the Culbin Sands is also proceeding apace. Mr. J. E. Annand, Forestry Officer for the north-east of Scotland, whose headquarters are at Craibstone, Aberdeen—the large experimental gardens, nurseries and farm attached to the agricultural chair in Aberdeen University—reports capital progress on the Culbins. By the end of the planting season this year, Mr. Annand hopes to have planted 2,240 acres with Scots Pine and Corsican Pine. This large area has all been planted with trees within the last six years—no mean accomplishment. Years must elapse, however, before the work is complete, much depending on how the moving sands can be fixed with Marram grass, and so enable trees to be planted. A hundred acres per annum is Mr. Annand's estimate of the progress he hopes to make. There is one fly in the ointment, however, and that is the rabbit pest. Rabbits are capable of doing a vast amount of damage to the young trees, and strenuous efforts are to be made to combat them.

Sweet Pea Exhibition in Holland.—The second national Sweet Pea Exhibition is to be held at Arnhem, Holland, on July 12, 13 and 14 next. Preparations are already well in hand, and it would appear probable that the great success which attended the show last year will be even surpassed. A number of valuable prizes have already been presented, and competition in the various classes should be keen.

Cattle Poisoned by Yew Leaves.—The *North British Agriculturist*, in its issue of April 4, reports that at Derbyshire Assizes, before Mr. Justice Hawke, Mrs. Sophie Locker-Lampson was sued by two of her tenant farmers, Messrs. James and Thomas Wilson, Carr Farm, Harthill, for £286 damages for the loss of thirteen heifers poisoned by eating leaves of Yew trees to which they gained access owing to the alleged defective condition of the fences. For the plaintiffs it was urged that it was customary for the owners of woodlands to repair fences. In giving judgment for the defendant, Mrs. Locker Lampson, his Lordship said that where there were wooden fences guarding plantations adjoining grasslands, the invariable rule was for the landlord to keep them in repair, except in cases where beasts belonging to the tenants had broken them down. This rule was due to the fact that the landlord wanted to protect his own plantation and game. He could not find there was any implied contract in the case. The plaintiffs' misfortune was probably due to the conduct of a huntsman in leaving open a gate through which the cattle passed. There was a good deal of hardship on the plaintiffs, and the case was one they had good ground for fighting, but he did not think the defendant was under any obligation to tenants to keep the fence in repair.

Mr. A. E. Burgess.—Few people really understand what the Horticultural Superintendent of a county really is, and what he does. As a matter of fact, he is a very busy man, and his work is very varied. A great part of his time is spent in visiting market gardeners, nurserymen, small holders, and even small gardens and allotments, in order to investigate the various problems which constantly arise, and to give advice. He is responsible for the supervision of school gardens, and conducts classes for the teachers who give instruction in the school gardens. He is usually present at the local flower shows to judge the produce and to advise the exhibitors, and he also judges the garden and allotment plots. He is in constant demand as a lecturer, and is also responsible for the lay-out and upkeep of school playfields and numerous other activities. Horticulture is an important industry in the county of Surrey, owing to the prominence of the nursery trade. The close proximity to London and the large residential population has led to the development of market gardening on a large scale. School gardening, too, is encouraged in the county, and nearly every school has its garden. The number of children receiving instruction weekly is well above 3,000. Mr. A. E. Burgess, the Horticultural Superintendent under the Surrey County Council, succeeded Mr. John Wright, V.M.H., in 1909. His early training was in the Essex trial grounds of Messrs. James Carter and Co. Later, he took a special course of training in the science and practice of horticulture at the Essex County School of Horticulture, at Chelmsford. At the end of the course he was given, without competition, a post on the staff, had charge of the gardens, and acted as Assistant Instructor. After about five years, he was appointed Lecturer in Horticulture to the Hertfordshire County Council, a post he held for nearly six years. In 1909 he was selected out of a large number of applicants by the Surrey County Council, and since that time he has endeavoured to encourage and help horticulturists in general, whether commercial or domestic. During the war period he was Secretary to the Surrey Horticultural Committee which was set up by the Ministry of Agriculture for the encouragement and stimulation of food production, and for his services in this connection he was awarded the M.B.E. In 1927-28, he was President of the Horticultural Education Association, and he is a member of the Royal Horticultural Society's Board of Examiners.



MR. A. E. BURGESS.

Gladiolus Hey Day (= G. Rufus).—This Gladiolus was figured in our issue of August 18, 1928. It was an unnamed seedling raised by W. Purple, of Canandaigua, New York, and Mr. George Churcher gave it the name of Rufus so that it might be put up for an award. A letter received on the 5th inst. from Mr. Purple states that he has now given the variety the name of Hey Day.

Horticultural Exhibition at Dinard.—At Dinard, the well-known French watering place, on August 9, 10 and 11 next, a horticultural Exhibition is to take place under the joint auspices of the French National Horticultural Society and the Dinard Municipality, the Minister of Agriculture having also promised his patronage. It will be held in the rooms and on the terrace of the small Casino, which has been placed at the disposal of the organisers by the proprietors. It appears that a number of English horticulturists have applied for space, and two sections have therefore been provided for, a French section and a foreign one; in each of these there will be seven classes, including one for sundries and one for manures. As the Exhibition will take place at the height of the holiday season, it ought to be well patronised by both French and English visitors.

Rainfall in the Thames Valley.—On the occasion of his re-election as Chairman of the Thames Conservancy Board, at the Annual Meeting of the Board on April 8, Lord Desborough stated that the Thames was passing through the most exceptional time in its history as regards rainfall. During the first three months of this year the rainfall, as gauged in the Thames Valley, was only 2·15 inches, the lowest ever recorded for the first three months of the year. The next lowest was in 1892, when the rainfall amounted to 2·90 inches. The standard average for this period is 6·45 inches, so that there was a deficiency of over four inches for the three months. He reported, however, that the flow of the river had been well maintained, and the water had not gone down much; all the weirs are closed to conserve the water, and the natural flow for the past three weeks had been about 800,000,000 gallons.

Essen Horticultural Exhibition.—The preparations for the great Ruhr Valley Horticultural Exhibition, to take place at Essen in the summer of this year, are almost completed, and the first of the special period-shows will be held from July 6 to 10, when hothouse and pot plants will be shown. From July 20 to 24, Roses will be exhibited, and from the 20th to the 28th of the same month, aquaria and terraria. The third special period will be August 3 to 7, which will comprise hardy plants, pot plants, Cacti, novelties, early fruits and vegetables. From September 7 to 11, Dahlias and Gladioli will have pride of place, and from the 21st to the 25th of the same month, market-, nursery-, and trade-plants will be exhibited. With the final period, October 5 to 13, during which Chrysanthemums, fruits and vegetables will be the chief attractions, the Exhibition will close, after a duration of over three months.

Sale of a Golf Course.—For many years the beautiful park and mansion house of Thrybergh, Yorkshire, have been in possession of the Rotherham Golf Club. The grounds extend to 141 acres, and are well-timbered, with much fine old turf. The estate, however, is now in the market, and will be offered for sale with possession from March of next year. It is on the outskirts of the busy manufacturing town of Rotherham, and unless purchased by the town authorities as an open space, is likely to go the way of so many beautiful estates, that is, it will eventually be covered with bricks and mortar.

National Bulb Society.—The first Exhibition to be held by this Society will take place on Tuesday, Wednesday and Thursday, April 23, 24 and 25, at Messrs. William Whiteley, Ltd., Bayswater. The schedule is in three sections :—(a) open to amateurs only ; (b) open to amateur gardeners' and horticultural societies ; (c) open to the horticultural trade. The cash prizes offered in each of the first seven classes are : first prize £3, second prize £2, third prize £1. Competitors must arrange their displays before 10 a.m. on the first day of the show, or, if unable to stage their flowers personally, they must send them by parcel post to arrive not later than April 23. Further particulars may be obtained from the Honorary Secretary, Mr. A. K. Lock, 9, Gower Street, Bedford Square, W.C.1.

Sulphur Fumes and Plant Life.—In the mining districts of northern Ontario, one of the greatest menaces to vegetation is the sulphur fumes escaping into the atmosphere. The Research departments of the horticultural colleges have, however, paid special attention to this problem, and a method has been discovered of capturing the fumes and turning them to economic account. As, at the present time, in some of these districts it is difficult to grow anything at all, the discovery will be of very real value. Furthermore, sulphur is imported very freely into the same districts, so that a double saving will be effected.

Kenya Colony.—The ninth Annual Report issued by the Department of Agriculture, at Nairobi, Kenya Colony, shows that the total area under occupation by Europeans on July 31, 1929, was 4,996,406 acres, or an increase of 258,486 acres on the previous year. The percentage of areas under the principal crops cultivated are, Maize, 36·4 ; Coffee, 14·2 ; Sisal, 15·5 ; Wheat, 14·9 ; Coconuts, 1·3 ; Sugar Cane, 1·6 ; all other crops, 5·9 ; with 11·4 of land under cultivation but not yet sown. The total area under Coffee is 84,073 acres, while Tea occupies 4,809 acres, giving a total of 33,403 lb. of Tea produced during the year ; it is estimated that the Sisal Hemp harvest for 1928-29 will be 365,000 cwts. About 473 acres are devoted to plants producing essential oils ; 9,408 acres are under Sugar Cane, and 7,994 acres under Coconuts, this last area showing a decrease of 119 acres on the preceding year. In regard to fruits, there appear to be 2,048 acres under general orchards, 391 acres under Bananas, 121 acres under Pineapples and 36,297 acres under Citrus trees. Interest is taken in Tobacco cultivation, and already 187 acres are devoted to this crop, while the cultivation of Castor Oil has declined from 965 acres in 1925 to 92 acres in 1928. Agricultural exports for 1927-28 amounted to the handsome sum of £2,839,492.

Botanical Society and Exchange Club of the British Isles.—The Report of this Society for 1928, now in preparation, and which it is hoped will appear in June, will include a new Monograph of the Batrachia, by W. H. Pearsall ; Palmate Orchids, P. M. Hall ; A New Hybrid Orchid, Dr. Heslop Harrison, F.R.S. ; Potamogeton natans, J. Gordon Dalgleish ; Rubi Britannici, W. Watson ; Sixteen New Species of Taraxaca, Dr. Dahlstedt ; New Sub-species and Varieties of Chenopodium, Dr. J. Murr ; A Flora of Ross-shire, G. C. Druce ; Paintings of British Brambles, Miss C. G. Trower, with descriptions by W. Watson, edited by the Secretary, with about twenty-five plates ; Chenopodium, nov. var. in Britain, Dr. Aellen ; Scirpus americanus Pers. in Lancashire, R. E. Baker ; Weingaertneria canescens in S. Lancashire and Circaea alpina in Carmarthenshire, by Mr. Justice Talbot ; Potamogeton Drucei in Dorset ; Galium constrictum (debile) in the New Forest ; Rosa Afzeliana at Blore, Stafford ; Bursa rubella in Surrey ; New Taraxaca ; Orchis praetermissa var. and Thymus zetlandicus, in Harris ; and Notes on the Flora of Cyprus, etc., G. C. Druce ; Alchemilla subcrenata, Buser, Cave Hill, with A. reniformis, Buser, Druce ; A. britannica, Jaquet and Druce, N. Aberdeen, M. Turreff ; Rosa Desvauxi, Dean Station, Mrs. Wedgwood ; Eryngium campestre, L., Guildford, Surrey, F. Clarke ; Hieracium praecox, Handcross, Sussex, Lady Davy ; Vaccinium intermedium, Ruthe, Dolgelley, Miss Vachell ; and in Derby and Yorks, Gourlay ; Pyrola rotundifolia, L., Bagley, Berks. ; Thymus zetlandicus, Ronn. and Druce, Isle of Harris ; Dondia fruticosa, Dr., Gibraltar Point, N. Lincs, D. W. Smith ; Betula pubescens, Ehrh., Zetland, W. R. Price ; Lolium remotum, Schrank, near Letterkenny, Donegal, Druce ; Pimpinella Saxifraga var. ovata, Sprengel, Cornwall, W. Tresidder, and E. Anglia, Mrs. Sandwith ; Crepis bulbosa, Anglesey, Horwood ; and Chenopodium mixtifrons, Didcot, Berks., and C. deltophyllum, Murr., both sub-species of C. album.

Appointments for the Ensuing Week.—Tuesday, April 16 : Royal Horticultural Society's Daffodill Show (old hall, two days). Wednesday, April 17 : Royal Horticultural and Arboricultural Society of Ireland's Exhibition (two days) ; Midland Daffodil Society's Exhibition (two days) ; Herefordshire Spring Flower Show. Thursday, April 18 : Royal Botanical and Horticultural Society of Manchester and Northern Counties Exhibition (two days) ; Ipswich Gardeners' Association's meeting. Friday, April 19 : Manchester and North of England Orchid Society's Exhibition ; National Rose Society's Show ; Tewkesbury Daffodil Show.

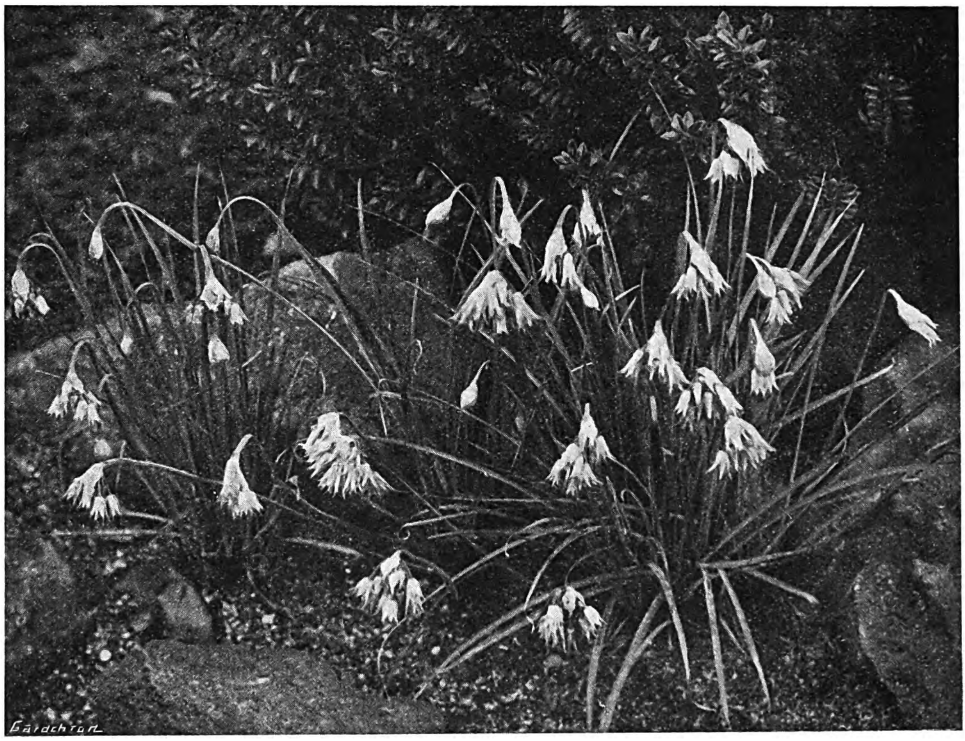


FIG. 141.—ALLIUM BEESIANUM.

(see p. 276.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Crystal Palace : Interior Planting.*—The report of progress in the grounds at Sydenham, which appeared lately in our columns, will have shown how rapidly the gigantic works in the park and garden there are approaching completion. To the decoration of the interior we have not hitherto alluded, nor are we prepared even now to say more than that we entertain no doubt that the effect produced within the building will be worthy in all respects of the exterior. It is, however, to be remembered that while effect is easily given to the open ground by shifting the position of large trees already growing there, it is quite different with the landscape gardening of the interior. For this purpose an abundance of tender plants of considerable growth is absolutely necessary, and they cannot be procured among the nurserymen. The purchase of Loddiges' noble collection by the Directors of the Crystal Palace, almost exhausted the plant market ; a few straggling specimens may have been procurable elsewhere, but their presence could scarcely be discovered in so vast a building. That such plants exist, however, plentifully in private collections, we have no doubt. Almost everybody who possesses large conservatories must have specimens either already too large to be confined within them or rapidly becoming so. The usual fate of such plants is destruction, greatly to the regret of those under whose eyes they have been reared for so many years. In the nave of the Crystal Palace they would find a ready welcome, such good treatment as would ensure their future health, and free space in which to develop their natural magnificence. We therefore venture to suggest that all who possess fine specimens of plants too large to be longer retained in their own conservatories should hasten to confide them to Sir Joseph Paxton, at Sydenham. Under any circumstances this would be better than destroying them ; we have reason to know that they would be gratefully received, and every donor would have the satisfaction of feeling that he, too, has contributed something to a palace which promises to become the eighth wonder of the world. *Gard. Chron., April* 15, 1854.

Publications Received.—*Perfumes, Cosmetics and Soaps, with Special Reference to Synthetics* ; Volume II, by W. A. Poucher ; third edition, revised and enlarged ; pp. 251, with sixty-six illustrations ; Messrs. Chapman and Hall, Ltd., 11, Henrietta Street, Covent Garden, W.C.2 ; price 25s. net.—*Starting Early Vegetable and Flowering Plants under Glass,* by C. H. Nissley ; pp. 302, illustrated ; the Orange Judd Publishing Co., 15, East 26th Street, New York ; price $3.00.—*Pruning Hardy Shrubs*, by A. Osborn ; and *Salads and Salad-making*, by C. Herman Senn, M.B.E. ; R.H.S. Pamphlets, revised, post free, 6d. each.—*Every Day in My Garden*, by F. Hadfield Farthing ; pp. 414, illustrated ; Alfred A. Knopf, 37, Bedford Square, W.C. ; price 7s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Cattleyas and allied Groups.—The numerous species and varieties of Cattleyas and Laelias, and the various hybrids derived from them, also many of the bi-generic hybrids obtained from the crossing of Brassavola Digbyana and Sophronitis grandiflora with the above, require similar cultural treatment, and may be treated as one group. The varieties are too numerous to enumerate, but collectively these Orchids form a remarkable and important group of gorgeously-flowered subjects. The flowers, many of which have a pleasing perfume, are in great demand for decorative and cut flower purposes, while well-flowered specimens are always very attractive. If a house is set apart for the cultivation of these plants, their requirements are more easily attended to. They thrive well in an intermediate temperature, which may be raised by sun-heat, as only sufficient shade is necessary to prevent scorching of the foliage, which will occur if direct sunshine is allowed to reach the plants after the leaves feel hot when touched by the hands; but shading should not be dense at any time. During the growing season a genial and moist atmosphere should be maintained, sufficient air being admitted to keep it buoyant. Water should not be afforded at the roots in large quantities, except when the growth is nearing completion and the roots are very active; the quantity required varies with the stage of growth, and much depends on the amount of light and air allowed to reach the plants, and the atmospheric moisture in the house, which should always be studied in conjunction with watering the roots. Drastic and sudden changes of temperature should be avoided so much as possible.

Repotting.—Many Cattleyas, etc., are now showing signs of activity, especially the late summer and autumn-flowering kinds. Any plants requiring fresh rooting material should be attended to at this stage. The spring-flowering kinds may be repotted as they pass out of flower. Plants to be dealt with should be carefully turned out of their receptacles, and all sour material and decayed roots removed, especially in the centre of the ball. Retain three or four sound pseudo-bulbs to each lead and pot them in well-drained pots, in a compost consisting chiefly of Osmunda or coarse A.I. fibre, adding a little chopped Sphagnum-moss and lump charcoal; this should be made firm among the roots, and the pseudo-bulbs should be secured to neat stakes. Large specimens should be repotted with a view to leaving them undisturbed for two or three years. After repotting, the surroundings should be kept moist, and the pots and compost surface sprayed frequently on favourable occasions to encourage root action. Very little water is required at the roots for some time, until root and growth action are well advanced, when larger quantities will be needed. Scale insects often attack the plants and should be removed by careful sponging.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Peach Tree Disbudding.—The disbudding of Peach and Nectarine trees is generally performed when the fruits have set. The work requires to be done very gradually and at an early stage, when shoots removed leave scarcely any scar; but if they are allowed to become somewhat woody at the base, the bark is liable to be torn in the process, and gumming and other diseases may follow. The first disbudding should be the removal of all badly placed and fore-right shoots when these are sufficiently long to be easily handled with the finger and thumb. In about a week or ten days time, a second thinning of the shoots should take place, this time preserving the most promising shoot or shoots near the base, one or two about the middle of the fruit-bearing branch, and one at the apex. These last-mentioned shoots are termed "sap drawers," and are stopped at the fifth or sixth leaf. All that is required of these shoots is to convert the sap into food material for the benefit of the fruits. When these fruits have matured, and are cleared, each fruited growth is pruned back to the successional shoot retained at the base. The only exception to this rule is when it is desired to extend the framework of the tree. Then the apical shoot on suitably situated branches should not be stopped, nor, for that matter, should the two laterals, but retained, in herring-bone fashion, to furnish the branch. No growth should be allowed where there is not sufficient space for the leaves to develop. This is an essential condition, as light and air are necessary for the ripening of the wood and to ensure fruitfulness.

Apricots.—The foregoing system, with some modifications, applies to Apricots. These fruit on the spurs, so well as on the wood of the preceding year. There should be an early removal of all fore-right shoots, which only result in useless breast-wood, and the thinning down of the side-shoots where these are numerous. Those retained should be stopped at about the fourth leaf to form spurs, although an occasional shoot should be allowed to extend unchecked to ensure a succession of fruiting wood, and laid in close to the branches from which they arise. With care and judgment in disbudding and stopping, winter pruning of Apricots may be reduced to a minimum.

The Watering of Wall Trees.—Owing to the exceptionally dry spell during February and March, when we registered less than an inch of rain, there is grave danger that wall fruit trees may be suffering from lack of moisture. These trees need abundance of water at this period, and where it is convenient to water with the hose-pipe, they should have a thorough soaking. A mulching of half-decayed manure applied now will help to conserve moisture and sustain a healthy growth on the trees.

The Pear Midge.—The adult insect appears from early April to the middle of May, and commences to lay its eggs in the blossoms, usually on the anthers. Sometimes there are ten or more eggs in each bloom. These hatch into minute maggots which infest the young fruitlets and eat out the interiors. By June they leave the decaying fruits and bury themselves in the soil until early winter, when pupation takes place. The application of kainit to the soil during June is recommended, when the maggots are entering the soil. Running poultry in the orchard from June to August has been found effective. About the only preventive measure that may be applied now is to spray the unopened flowers with soft soap and Nicotine to prevent egg-laying. This wash is made up as follows:—To make one hundred gallons of spray, dissolve 8 lbs. of soft soap by boiling, and add this to one hundred gallons of water; then add 5 oz. to 6 oz. of Nicotine. Mix thoroughly and apply with a coarse nozzle on the sprayer.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Vines.—As days increase in length and the sun gains power, work in forcing houses will increase daily. Vines and other fruits will require greater quantities of tepid water and copious syringings twice a day. When the Grapes have finished stoning, attend to the final thinning of the bunches, see that all ties are sound and not too tight, and keep a sharp look-out for red spider on the foliage in dry corners. If red spider puts in an appearance, sponge at once with warm soap water, but the best preventive is good inside mulching and liberal feeding with warm, diluted liquid manure, and good syringing with clean soft water wherever the foliage can be reached without spraying the berries. If laterals continue growing freely—the best proof of moderate cropping—all the weakest may make full growth, but the strongest should be pinched, otherwise they prevent a free circulation of air, which may result in scalding of the main foliage. A little night air is an excellent preventive of scalding, but it should be shut off early in the morning for the two-fold purpose of economising fire and favouring the early re-opening of the ventilators for the day. Successional houses, in which the vines are in various stages, will now require incessant attention, as nothing pays better than performing every operation at the right time. Disbudding is a piecemeal operation, but once the work is finished the shoots push on apace, and in a few days the most forward are ready for the removal of superfluous bunches, stopping and tying down. Some vines are more tractable than others, but in all cases pressure at the first operation of tying the growth in should be very slight, as it is better to allow them time to settle down by degrees than to break them by undue haste. Stopping the growths should not be delayed, as every leaf made beyond the second or third joint after the bunch represents wasted energy.

Late Vines.—This year these vines are later than usual, and should now be helped forward by moderate fire-heat, early closing, and a good syringing with tepid water twice a day. Years ago, spring firing was considered unnecessary, but this trusting to fickle seasons has gone. Where all border space has been made up, a thorough mulch of fresh, rather short, good stable manure is a great help, not only as a root stimulant, but as a never failing source of atmospheric moisture. Late Grapes need a temperature similar to that required by Muscats—55° on cold nights, 65° to 70° by day, and 75° to 80° with sun-heat and moisture after closing, will not be found too high from the time the buds begin to break until the bunches are prominent. From this stage forward another 5° may be given at night and still more by day, when 65° should be the minimum. When the vines come into flower, warm diluted liquid manure may be given to old vines that need it, and tepid water only to young vines; cold, stagnant water should never be used.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens Wisley, Surrey.

Evergreens.—Where evergreens are to be planted in quantity, no time should be lost in commencing and completing this interesting work. The sap of these will soon be rising and root action will commence almost at once. Choose, if possible, dull, showery weather for this work; if dry conditions prevail, then spray them overhead during the evening; large specimens will benefit greatly by this treatment. In every case, irrespective of the weather conditions, leave a basin around each plant and give a thorough soaking of water. Afterwards apply a good mulch of half-decayed leaves or other vegetable matter to check evaporation. Stake all large specimens securely to prevent them being damaged by wind.

Sweet Peas.—Seeds of these popular annuals should be sown in the open at the earliest possible opportunity on sites prepared previously. Those raised under glass may be transferred to their flowering quarters in mild, sheltered districts, provided they have been thoroughly hardened off. From the point of view of garden decoration, nothing is so satisfactory as good Hazel stakes as a means of support. Whether grown in lines or clumps, do not overcrowd the plants—from six to nine inches apart will be close enough. Give support immediately after planting by placing small, twiggy sticks around them; this will also give the necessary protection from ground frost.

Seed Sowing for Spring Bedding.—Seeds of Polyanthuses and Primroses should be sown under glass and the resultant plants hardened off gradually so soon as large enough to transplant to the open border. By sowing now, large plants will be secured by autumn, which will flower profusely the following spring. Choose a half-shady, moist position for the growing quarters during the summer, as they very soon object to drought. Seeds of these come fairly true to colour, especially the white and yellow Polyanthuses. A good strain of the Blue Primrose is always welcome in the garden; seeds of this are rather irregular in germinating, and for this reason it is wise to keep the seed pans for a considerable time and, like all Primula seeds, they should never be allowed to become dry.

Spring Bedding.—The beds and borders containing spring-flowering plants should be hoed, as the surface in many cases has become consolidated. Remove all decaying foliage, of which there is a considerable amount on such plants as Polyanthuses, etc. Daffodils, Hyacinths, Tulips and other bulbous plants will all benefit by having the soil stirred around them.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain,
Brocket Hall, Hertfordshire.

Salvia splendens.—This Sage is a fine subject for growing in the conservatory, and also for grouping in the dwelling-house. Old plants that were cut back late last year should now be producing strong shoots which should be secured as cuttings; these will root readily in a propagating frame in a warm greenhouse, and so soon as they are rooted they should be potted singly into small pots. During the early stage of growth they should never become impoverished, but should be kept growing freely in the greenhouse or frame until the final potting. S. splendens, in its many varieties, is a gross feeder, therefore a good, rich compost should be used, one similar to that employed for Chrysanthemums being suitable. After the final potting the plants may be placed out-of-doors in a position shaded from the direct midday sun. During late summer and autumn they should be fed liberally with soot-water and liquid manure. The growths should be stopped at intervals until about six weeks before they are required to flower. If necessary, a later batch of cuttings may be inserted about the first week in June to produce plants for flowering during mid-winter. Watch for red spider, which attacks these Salvias if they are grown under dry conditions, and if this pest appears, dip the plants in a weak solution of Volck, or some other insecticide.

Begonias.—Tuberous-rooted Begonias may now be started into growth in boxes, the compost at this stage consisting chiefly of leaf-mould and sand. Where some were started into growth earlier, they should now be ready for potting off singly, the size of the pots employed depending on the size of the tubers. The compost for this potting should be on the light side, but for subsequent pottings the soil may be of a heavier nature, care being taken to ensure good drainage. Seedling Begonias, raised as advised previously, should now be ready for pricking off using pots for preference.

Gloxinias.—As growth advances, Gloxinias should be potted on into larger pots, in a compost of turfy loam, peat, leaf-mould and coarse sand. Gloxinias require a moist atmosphere and shade from bright sunshine, and so soon as the receptacles are well filled with roots liquid manure should be given twice a week. Seedlings raised in January should now be ready for pricking out singly in small pots.

General Work.—As seedlings of Streptocarpus, Grevillias, Asparagus medeoloides and Asparagus plumosus, Clerodendron fallax, etc., become ready for transplanting, pay strict attention to their requirements and keep them growing steadily, never allowing them to remain in soil that has become soured.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Peas.—Further sowings of mid-season Peas should be made. The distance between the rows will naturally depend on the height of the variety or varieties employed. The seedlings should be staked early, and a mulching of short litter should be placed between the lines to keep the ground in a moist condition.

Potatos.—The planting of early Potatos should be completed so soon as possible, after which the second-earlies may be attended to.

Marrows.—Marrow seeds may be sown now in four-inch pots. A good system of growing Marrows is to plant them in specially prepared beds of one foot depth, filled with good turf and decayed manure mixed well together and made fairly firm by treading. If plenty of turves are available they may be built up around each bed to permit of flooding when the Marrows are in active growth.

Asparagus.—Now is a suitable time for planting new beds of Asparagus, provided the ground has been prepared thoroughly. The surface of the bed should be forked lightly and made level, after which the plants may be put in with a trowel, making the holes of sufficient size to allow the roots to be spread to their full length.

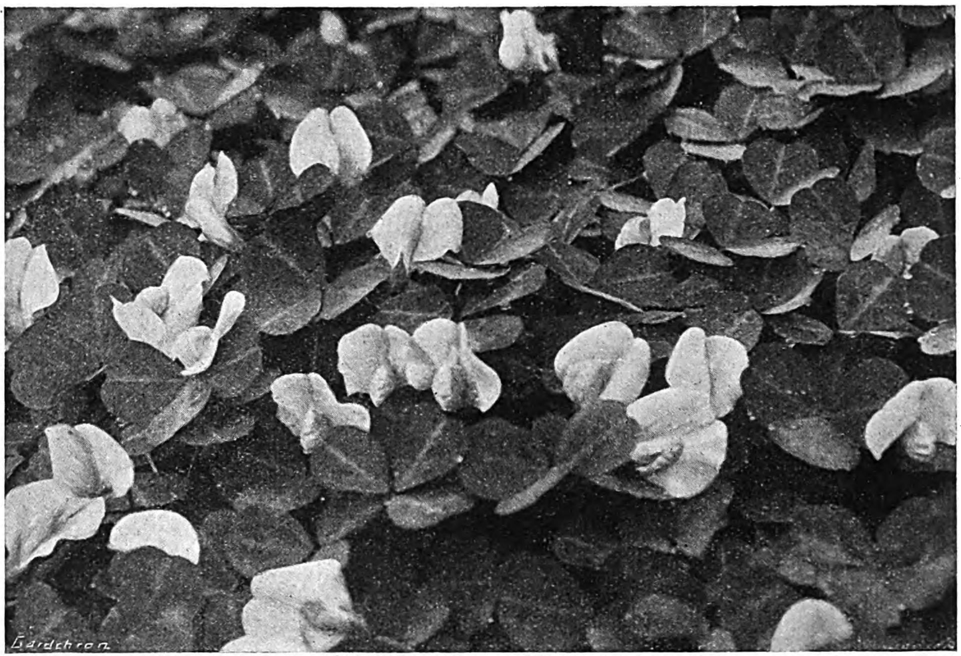

FIG. 142.—PAROCHETUS COMMUNIS.
(see p. 276.)

Salsify.—Salsify and Scorzonera may now be sown in deeply-worked soil, allowing sixteen inches between the drills, which should be two inches deep. When the seedlings are large enough, thin them to not less than one foot apart.

Brassicas.—Final sowings of Cauliflower, Cabbage, early and late Broccoli, Kale and Savoys, may be made with a view to securing good stocks of plants.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemount, Monkton, Ayrshire.

French Beans.—Successional sowings should be made to keep up a regular supply, for French Beans are always in demand. If grown in pots, a larger size—ten-inch,—should now be used, as the plants will be more vigorous than the early ones. Feed these with liquid manure, applied in small doses when the soil is wet, and give an occasional application of an approved chemical fertiliser.

Brassicas.—The main sowing of these should now be made to provide a supply from late autumn to next spring. Little trouble is being experienced in preparing seed-beds this year as the ground has seldom been in better condition. But, even so, it is advisable to take no risks on soil that is naturally heavy, and the seeds should be covered, as usual, with old potting soil. Thin sowing should be practised and the bed covered with netting as a protection from birds.

Second-early Potatos.—These should now be planted, the distance between the rows and sets being regulated by the variety used, as some produce much stronger haulm than others, and it is a mistake to crowd the plants. The advice governing early plantings applies also to this crop.

Early Cauliflowers.—These may now be planted out in a warm border which has been well prepared. Early varieties, such as Sutton's First Crop, if treated generously and watered in dry weather, make beautiful little heads, but under poor cultivation they merely form "buttons." Even although well hardened off, some protection for the plants should be kept at hand and applied in cases of sharp frosts, or great damage may result. Flower pots of a suitable size inverted over them afford admirable protection, and are easy to handle.

Annuals.—Most hardy annuals may now be sown in the open, and many of them, if carefully treated, make a grand display over a long period. The ground chosen should be light and sandy, if possible, and not liberally manured, or the result will be luxuriant growth at the expense of flowers. If required for cutting, they are best grown in beds, Malopes, Lavateras, Lupins, Nigella, Eschscholzia, Larkspurs and many others being invaluable for this purpose. The above-named sorts should be thinned to at least twelve inches apart, and care should be taken to select seedlings of moderate or event weak growth for retention, as in most instances these give the best results. If grown for display, the group system of sowing is much the best. It is easiest to sow them in shallow drills one foot apart, with other drills crossing them at right angles so as to secure irregular groups. Thinning should be done early and thoroughly, the ground frequently hoed, and a few twiggy branches given for support. If space permits, large patches should be sown, as they give much the best effect.

ALPINE GARDEN.

SAXIFRAGA ELIZABETHAE.

In long past years those of us who admired the Saxifrages ardently desired a good yellow-flowering Kabschia species or hybrid which would flower more freely than the two best known at that time—S. sancta and S. juniperifolia. The position was complicated by the fact that what was sold as S. sancta was generally the inferior S. pseudo-sancta, and it was not possible to have flowers with any profusion on S. juniperifolia, which some of us had to cover with a sheet of glass for the greater part of the year to induce it to flower. Nowadays, we are more fortunate in the possession of free-flowering yellow Saxifrages of the Kabschia section, and among these, S. Elizabethae soon acquired and retained a high place. It bears the name of the late Queen, Carmen Sylva, of Roumania, and has for its parents S. Burseriana and S. sancta. The foliage is spiny, as in S. Burseriana, but of a deep green, and the plant forms a more spreading mass, but is, all the same, remarkably neat. In early spring it is thickly spangled with clear, soft yellow blooms, smaller than those of S. Burseriana, but of much purer yellow than those of S. sancta. They are borne in loose heads on two-inch, pink stems.

The habit of the plant is good, but it appears to the writer that there are two plants grown under the name of S. Elizabethae. The one forms a much closer, denser mound than the other, and is the better form of the two. In cultivation, I find S. Elizabethae very easy in poor, stony soil, with annual top-dressings of sand and loam, and some grit well worked among the foliage in autumn. I give it full exposure and grow it both in a moraine and in the rock garden. The only failing the plant has—and it is one common to many rock plants—is that the centre of the mound, when the plant becomes large, is liable to become bare. Should this happen, which it is almost certain to do, the plant must be lifted and taken to pieces, inserting these in soil composed of loam, sand and grit. I may add that this year S. Elizabethae is late, and to-day (March 20) it is only in bud, awaiting a little more favourable weather to delight us with its bright flowers.

ANEMONE RANUNCULOIDES.

It is pleasant to see that your able contributor, *M. W.* (p. 200), speaks so favourably of Anemone ranunculoides, although he cautions the reader to avoid planting it where it might encroach upon other subjects. I agree with all he writes about this bright little Anemone, and I should like to mention two varieties of A. ranunculoides which are, or were, recently in cultivation. The one is the double variety, A. ranunculoides fl. pl., which is in commerce, and is quite a good little plant, although some do not care for it on account of its flowers being double. Yet it is quite pleasing and suitable for any place where the single form is grown. I do not seem to have seen the other variety offered in catalogues for some time, but it is a very desirable plant, and one which I grew for a number of years. I received it originally as A. ranunculoides var. pallida, but I have observed it named A. ranunculoides var. sulphurea. I first obtained it somewhere about 1906, and to my mind it is even prettier than the type. The flowers are of a pale sulphur-yellow, slightly paler than those of the hybrid A. Seemannii, and are of similar size to those of the typical A. ranunculoides. These forms of A. ranunculoides are all good for carpeting of dwarf, early bulbs, and, in the case of singles, where grown along with or near A. nemorosa, there is every possibility of the hybrid A. Seemannii appearing among seedlings. *S. Arnott.*

GYPSOPHILA CERASTOIDES.

Among the numerous beautiful rock garden plants that the Himalayas has given us is the diminutive and very attractive little Gypsophila cerastoides, a distinct, non-trailing member of this popular genus.

It forms neat, close-growing and spreading tufts of hairy foliage, above which, on stems two inches or so high, the comparatively large flowers are produced during May and June; they are white in colour, delicately veined with purple.

G. cerastoides presents no difficulties in the matter of cultivation, being at home alike in a crevice or on the level, in not too hot and sunny a position, and in loamy soil to which a little leaf-mould and grit has been added to ensure good drainage in winter. It is hardy, and by no means difficult to increase by either cuttings or division, while it may also be raised from seeds. *Kent.*

BULB GARDEN.

ALLIUM BEESIANUM.

So far as can be ascertained, specimens of this exquisite plant collected by Mr. G. Forrest in 1904, were described and named by Professor W. Wright Smith in *Notes* of the Royal Botanic Garden, Edinburgh, Vol. VIII, p. 176, in 1914. It was there stated as coming from the eastern Lichiang range, in western China, where it occurs at altitudes of 12,000 feet and upwards.

Allium Beesianum (Fig. 141) is very closely related to both A. cyaneum and A. kansuense (the latter is figured in the *Bot. Mag.*, t. 6,451); they all come from the same district in western China.

The flowers are borne in hemispherical umbels one-and-a-half inch in diameter, which nod their heads likes groups of hyacinth-blue stars at the apex of slender, stiffly-erect, glaucous-green stems some eight to fifteen inches in height. The individual flowers are somewhat campanulate in shape, a quarter-of-an-inch in breadth, and one-eighth-of-an-inch in depth when fully expanded, with pedicels of half-an-inch to three-quarters-of-an-inch arising from the base of a beautiful, membranous spathe.

The leaves, like the stems, are glaucous-green, rather flat in shape, twelve inches or more in length by a quarter-of-an-inch in breadth, emitting, when bruised, the strong Garlic odour of the tribe, and having the usual trailing habit of that particular section.

Once well established in comfortable surroundings, for A. Beesiana is by no means fastidious as to soil, the bulbs will quickly multiply and provide a host of flowers from the beginning of June right on into August, when flowers on the rock garden are on the wane. The species may be regarded as quite hardy, for in the rock garden at Kew the clump appears to be even larger this year than last, even although it has been exposed to extremely severe weather. *A. Edwards, Kew.*

HARDY FLOWER BORDER.

SYMPHYANDRA PENDULA AND S. HOFMANNII.

These two members of the small genus Symphyandra, which is closely related to, and therefore inclined to be over-shadowed by, the genus Campanula, are valuable subjects for the front of the herbaceous border, both being free-growing and prolific flowering during the later part of the summer. S. pendula is the most attractive of the race, for it forms a large mound, nine inches or so high, and quite eighteen inches to two feet across, of soft, bright green foliage, which is smothered from July onwards (for quite two months) with the lovely, indeed, exquisite, large, campanulate bells of wax-like texture in the most delicate shade of creamy-white, with just the faintest tinge of green, which does not, however, detract from their beauty, and these are produced in such lavish abandon that they weigh down the branched stems, and their beauty would be lost were it not that they form a complete mound of creamy-whiteness. However, a few light twigs of Hazel placed among the flower sprays as supports improve the attractiveness of the plant considerably by lifting the lovely bells and exposing them better to view. S. pendula is also very effective when grown on the rock garden, where it should be planted on a ledge above the level of the eye, when its flower sprays will need no support and its blooms may be viewed in all their exquisiteness.

S. Hofmannii is more erect in habit, and attains a height of eighteen inches, the branched growths being clothed with whitish, bell-shaped blooms, beautiful, but in some way lacking the appeal of S. pendula. Moreover, S. Hofmannii is a useful subject for growing in cool, shady positions, conditions which it would appear to prefer.

Both these Symphyandras are generous in the production of seeds, which germinate with unquestionable freedom, and provide the best means of obtaining fresh stock. They should be grown in deeply-worked and well enriched soil, for there is nothing delicate about their constitution and no lack of freedom in flowering results from generous treatment; they are both perennial, but, perhaps not so long-lived as many of the commoner herbaceous subjects, and may require to be replaced every few years with fresh young plants.

There are other members of this genus in cultivation, notably the lovely S. Wanneri, which requires, however, to be confined to the rock garden, for it is of dwarf habit, its flower-bearing stems being spreading and flattened on the ground, the branching lateral growths all bearing lovely campanulate bells of rich violet-blue, very beautiful. But S. Wanneri lacks the constitution of S. pendula and S. Hofmannii, and often it dies down after flowering, seemingly to seek rest after its magnificent efforts, and fails to appear again. *M. W.*

BOG AND WATER GARDEN.

PAROCHETUS COMMUNIS.

Although not usually considered hardy, some large patches of this interesting plant have survived the severe frost, tender green leaves now (early April) appearing among the bleached and very lifeless looking tangle of last year's growths. On other occasions I have noted that while strong old plants of P. communis, especially those growing in or near the bog, will survive, smaller ones in drier and more sheltered spots have succumbed. Further, of the several slightly different forms of this plant some are undoubtedly more robust than others. The most vigorous grower here has rather pale green leaves, the usual purple or slaty markings on the leaflets being all but absent. This one seems able to withstand anything, and to grow anywhere with extraordinary heartiness, whereas another with leaves of a darker shade, with stems and leaflets stained with purple, and flowers of a richer blue, is comparatively feeble and shy.

P. communis (Fig. 142), a Himalayan plant with a remarkable likeness to a Clover in its leaf and manner of growth, always surprises those who do not know it, not only by producing Pea-flowers, but these of a blue not less pure and rich than that of Gentian verna. The dense crop of leaves does not rise more than about four inches above the mat of trailing, rooting stems, and the flowers, borne singly or in pairs, just peep out of their forest of green with a most charming effect. In a warm, moist soil with full sun, a lusty plant of P. communis will envelop a square yard in the course of the season. The first flowers usually appear soon after mid-summer, and from their coming onwards to the first frost an unbroken succession of bloom will be maintained. This is a first-rate waterside plant, but it often does well in the rock garden, provided it has a good vegetable soil and does not lack moisture in summer. It is easily increased by division and those who deem it desirable to winter a stock in a cold frame will have no difficulty, since any rooted scraps will survive if potted up. These should be put out early in May. *J.*

PLANTS NEW OR NOTEWORTHY.

RHODODENDRON SP. (FORREST 21,488).

This Rhododendron, apparently of the 'Racemosum' series, is an upright-growing bush, two to three feet in height, well furnished with oval leaves, one-and-a-half to two inches long, three-quarters-of-an-inch broad, slightly cordate at the base, with a small mucron at the apex. They are deep green on the upper surface, glaucous underneath, and aromatic when crushed. The stems are slender, reddish-brown in colour. Flowers axillary, in groups clustered at the tops of the stems, not spread down them, thus forming a rather conspicuous head. Each flower is three-quarters-of-an-inch across, very open, a clear rose colour fading to delicate pink. The stamens are prominent, the style is long, considerably exceeding the stamens in length.

This is an attractive shrub; it appears to be hardy and, as it flowers freely during the second and third week of March, is a valuable addition to the smaller Rhododendron series, which are so suitable for planting at the edges of Rhododendron beds or in the alpine Rhododendron rock gardens, which are deservedly becoming popular.

In the Field Notes of Rhododendrons found by Mr. George Forrest in 1922, No. 21,488 is described by him as "Rhod. species ? (section ?) Shrub two to four feet. Flowers ? In fruit. Foliage aromatic. Open situations amongst rocks and scrub on the margins of forests on the Chien-Chuan Mekong Divide."

He adds this note:—"Certainly new to me, rather a striking plant distinguished by its broadly elliptical foliage, the grey under-surface of same, the persistent flower and leaf-bud scales. From examination of dried fragments, I should say the flowers are rose ? "

The plants here described are growing at Headfort, Kells, Co. Meath, in a clearing on an island, in the natural soil which is not altogether free from lime. The trees on the island are chiefly Oak, Beech, Ash, Sycamore, and Scots Pine of mature growth. The deposit for many years of the leaves of the hardwoods seems to have added sufficient humus to the soil to neutralise such lime as is in it. Many big-leafed Himalayan Rhododendrons are planted in similar clearings with satisfactory and encouraging results. *Phylis Moore, Willbrook, Co. Dublin.*

TREES AND SHRUBS.

DAPHNE CNEORUM.

It would be difficult to mention any rock garden flowering shrub which rivals Daphne Cneorum, and it is excelled by none. Not only does this delightful European species blossom copiously, but its flowers are a very attractive shade of pure deep pink, and generously fragrant. Then its habit of growth is good, its foliage is a pleasing green at all seasons, and the plant is usually at its best in spring, maintaining a show of blossom throughout the most important period of the rock garden year.

That D. Cneorum is not always an easy subject must be admitted. Like others of its race, it has its likes and dislikes in regard to soil, and if it is not actually difficult it is sufficiently fastidious to excite the enterprise and test the skill of the grower. What the conditions are which this Daphne needs one hardly dare suggest, since it may often be seen doing remarkably well in one garden under treatment which it would disdain in another.

In central and southern Europe it is generally found growing in peat overlying limestone, and most authorities seem to agree that lime in some form is essential. In my own garden, however, where there is no lime, the red, gritty loam being acid and full of iron, D. Cneorum grows abundantly, some of the oldest plants each covering a space between three feet and four feet across (Fig. 143). All they ever get in addition to the natural woodland loam is leaf-mould, which, of course, is also acid, and I find no appreciable difference in results between plants thus treated and those given lime. The soil, I may add, is very sharply drained, and becomes exceedingly dry during rainless periods in summer. A light top-dressing of leaf-mould and sand is given occasionally, but layering is not attempted as a regular practice. That this latter might prolong the life of a plant is not doubted, but I find it better to discard old specimens so soon as they get lanky, and replace them with new ones.

D. Cneorum varies somewhat in the size of the flower clusters and the compactness of its growth, a form usually listed as var. major being much superior to the average wild plant. Then there is a white one, and the curiously distinct D. C. var. Verlotii, with its smaller and looser flower heads. *A. T. J.*

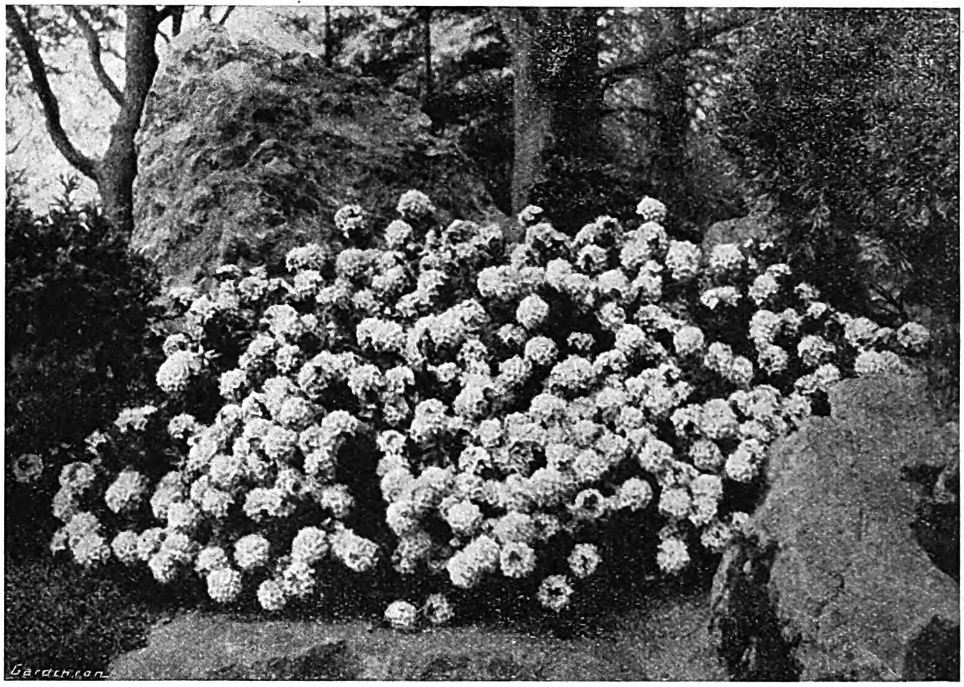

FIG. 143.—DAPHNE CNEORUM.

SPIRAEA DISCOLOR.

Shrubs flowering in late summer are not so plentiful that we can afford to omit this example from our gardens; nevertheless, S. discolor (syn. S. ariaefolia) should not be planted unless there is ample room for its proper development, since it will grow into a big, spreading bush eight or ten feet in height, and as much through. It is preferable to grow it as an isolated specimen (just as Berberis stenophylla should be), so that its long shoots may effectively display their creamy plumes without being fettered by obstructive neighbours. A wise gardener, too, would take care that a darker background was present to augment the beauty of this shrub —Conifers or evergreens used as windbreaks are excellent for this purpose.

For approximately a century the name S. ariaefolia has been in common use for this shrub, but so far back as 1830 John Lindley expressed his dissatisfaction that this group should be included under Spiraea, since it differed from that genus both in habit, foliage and fruit—in the latter character the carpels are one-seeded in the plant under notice, but several-seeded in most Spiraeas. In American text-books, the recognised name is Holodiscus discolor var. ariaefolia; in the type the leaves are whitish-tomentose beneath, but in the variety ariaefolia, grey-green and pubescent. Whether this rather cumbersome title will ever come into use in this country is another question; but it would appear, at all events, to be botanically correct.

The easiest method of increase is by hard-wooded cuttings, taken in late October or early November, and inserted either in a sheltered spot outside, or under the protection of a cold frame; in either case they will root readily, and growth is rapid when they are planted out into their permanent quarters. As regards soil, this Spiraea is not particularly fastidious, provided the site is well-drained, but the flowering qualities are often better in a poor, rather than rich soil. In pruning, which may be carried out in November, first remove all weak growths, then the old flowering wood, provided there are sufficient young shoots to replace this; if not, then merely spur back each lateral shoot to within one inch of the base.

S. discolor is a native of western North America, including British Columbia and California, and was originally discovered by Menzies; it was introduced, however, by Douglas, about 1827. It is figured in the *Botanical Register*, t. 1,365, and there is a supplementary plate, depicting a large specimen, in *The Gardeners' Chronicle* for October 11, 1902.

OLEARIA VIRGATA.

From other members of the genus, O. virgata, together with its close relatives, O. Hectori and O. Solandri, stands quite apart in habit, foliage, and the manner in which the flowers are borne.

It forms a tall, slim shrub, growing to over twenty feet in height, and should therefore be planted towards the back of the border; there are usually several main stems arising from near the ground level, and from these a perfect shower of slender, graceful branches descends, so that its beauty is appreciated even in mid-winter. Frost seems not to affect it at all. The leaves are opposite, from a quarter-of-an-inch to one inch long, linear-oblong, spathulate at the tip, and covered beneath with a white tomentum; in the case of O. Solandri this tomentum is yellowish, while in O. Hectori the leaves are from one inch to two inches in length, with the veins distinctly marked.

The flowers are rather inconspicuous and not particularly attractive in any way; they are borne on short pedicels, either solitary—which is usually the case with young bushes—or in clusters; the white ray florets, from five to twelve in number, being the most obvious parts.

This shrub is a native of New Zealand, being found in both North and South Islands, and also in Stewart Island. In these habitats it seems to prefer damp or even boggy positions, but in cultivation it will thrive perfectly well even in very sandy soil in the open border; it will produce flowers when three feet high.

There is an excellent figure of it in Cheeseman's *Illustrations of the New Zealand Flora*, Plate 91, which depicts the branching and inflorescence of this unusual shrub. *B. O. M.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XVIII.—On the Threshold.

APRIL 21 was wet, and we spent the day in camp. On the following day I climbed the ridge, finding several Rhododendrons. The next two days I took short local walks in the valley, and on the 25th, our last day here, we went up to the top of the ridge, nearly 9,000 feet, from where we saw the divide ahead of us. Below our camp the stream was lined with subtropical forest, Tree Fern, Altingia excelsa, Elaeocarpus, climbing Bauhinia, and a fine species of Pentapterygium with flowers two inches long. So much emphasis is laid on Rhododendrons, and from the horticultural point of view rightly so, that one is apt to overlook the fact that there are a great many other genera and species of Ericaceae in these forests. Possibly there are as many species of Rhododendron as all other Ericaceae put together, and in sheer bulk, of course, there is no comparison; if all Rhododendrons were swept away, the effect would be monstrous, whereas if all other Ericaceae were wiped out, leaving only the Rhododendrons, one would hardly notice anything wrong. Even so, the smaller Ericaceae are a feature of the vegetation, and the botanist, at any rate, would miss them if they were absent. I collected over thirty species, distributed somewhat as follows:—Pieris about five species, Vaccinium about nine, Gaultheria nine, Pentapterygium five, Agapetes two, Cassiope two, Enkianthus two. Many of these were more or less familiar to me, some having been collected in the Seinghku valley in 1926 for the first time. Among well-known species were Pieris ovalifolia, Enkianthus himalaicus, Cassiope selaginoides and Pentapterygium serpens. Of the new species, few were out of the common; a Pentapterygium was noteworthy for its large leaves, and a Gaultheria for the blood-red colour of its breaking leaf-buds.

It was no great climb from our camp to the beginnings of the forest where the first Rhododendrons were met with—R. arboreum, R. dendricola, the 'Stamineum' and 'Big Bill.' A little higher up were at least half-a-dozen species of Oak, Magnolia rostrata as usual, Birch, and a new species of Engelhardtia, its small, Elm-like leaves furnished with drip tips. That such tailed leaves, although characteristic of tropical forests, are really a rain and not a temperate phenomenon is proved by their frequency in these temperate forests; species of Quercus, Ilex, Ficus, Engelhardtia, several Ericaceae, and other trees and shrubs displayed them.

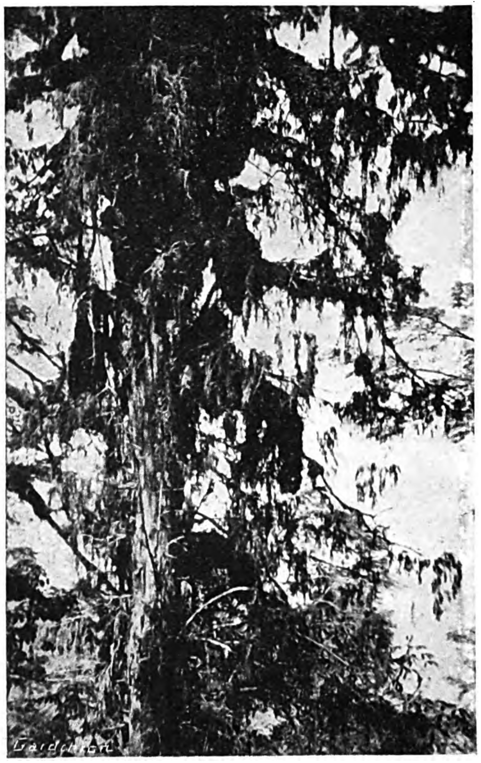

FIG. 144.—A HUGE JUNIPER FESTOONED WITH MOSS AND LICHEN.
Temperate Rain Forest, 9,000 feet alt.

The next forest Rhododendron met with was a small tree 'Neriiflorum' with waxy flowers of swarthy scarlet and small, oblong leaves, blue-grey with wax beneath. From the garden point of view, it was remarkable for the lasting quality of the flowers, dangling bells whose molten colour rings sharply against the cool glaucous alloy of the foliage. First seen in flower on April 22—and it must then have been open some days—it was still flowering merrily, elsewhere, in the third week of June. One particular bush I kept my eye on lasted three weeks, and that in spite of perpetual rain. From the botanical point of view, it was remarkable for the crimson-headed, glandular hairs on petiole, pedicel, and young growth. It is at home in the temperate rain forest, where its sleek, copper-red trunk and contorted branches are a familiar sight between 7,000 and 10,000 feet; but it is not likely to display its real worth before it is mature.

On a windy ridge were huddled together quite a collection of shrub Rhododendrons, one of the best being akin to R. aureum, but with paler flowers of a more refined yellow and leaves not deciduous. There were fine blobs of bloom on it, and although they lacked the hard glitter of R. aureum, this was not to their discredit.

Two first cousins of the 'Maddeni' family struggled in the tanglewood. One looked like R. Maddeni, the head of the house, but it had larger leaves. The squat, mahogany-red flower buds were tightly shut, and did not open until July, when the flowers recalled R. crassum rather than R. Maddeni. However, there should be plenty of three-year-olds of this fine summer, lily-white Rhododendron at home, since I collected it in the Di Chu valley in 1926.

The second was R. megacalyx, which was just coming into flower. It has become increasingly clear of late that the 'Maddeni' Rhododendrons, (among others) are not, individually, quite so restricted in their range as was believed when Hutchinson published his monograph of them then years ago.* Take R. megacalyx as an example. Since I first found it on the Burma-Yunnan frontier in 1914, I have collected it as far north and west as the Tsangpo gorge in Tibet, in 1924, and at two intermediate points, giving it a continuous distribution from the eastern Himalayas practically to Yunnan. Other species also have since been found wandering beyond the bounds then assigned them—R. Lindleyi, R. Nuttallii and R. dendricola, for example. R. megacalyx is without question a grand plant, and when I saw it in full bloom again at the end of May, with six-flowered trusses, I ranked it as high as anything in its class. Unfortunately, it is tender, at least no hardy form of it has been collected yet. The Delei valley form (and for that matter the Seinghku valley form) promises to be as hardy as any, coming from 8,000 feet; but delicate health is constitutional rather than typographical. The Burmese form, and also, probably, the Tibetan form from the Tsangpo gorge, both brought up in the lap of luxury, are likely to be expunged from the open in Britain. But, like R. Nuttallii, R. megacalyx will survive under glass by sheer merit.

Rhododendron bullatum—or its double—also grew here, but the flowers were over. By far the best of the smaller bush species, however, was a chrome-flowered 'Boothii,' which carried a neat head of vivid yellow, red-anthered blossoms, whose dazzling complexion more than compensated for an awkward figure. It is a leggy stripling, as shrubs which pull out of the struggle and betake themselves to sun-baked rocks, there to mope alone, are apt to be; the leaves, too, are odd-looking, hairy, dark green above, and wine-purple below. At first glance they appear to be only hairy, the petiole fairly bristling, the margin with long, curly hairs; but closer inspection shows that the under leaf surface is, in fact, densely lepidote as well as hairy, each scale sunk in a deep pit, for which reason these scales are overlooked until the surface is examined under a lens. This is one of the best and brightest yellow-flowered Rhododendrons I have ever seen; if it proves hardy, as it well might do, and keeps a trim figure, it ought to go far.

But to the botanist, this species is chiefly of interest for the great cunning it displays in the cross-pollenation business; it is, indeed, a crossword puzzle of high artistic merit, and it took me some time to solve it. If it does not ensure cross-pollenation it certainly deserves to. The contrivance is as follows. The corolla is flattened, and stands on edge, that is, more or less parallel to the pedicel. The three upper or posterior lobes are spotted with mahogany and have broad bands of pubescence reaching from the base of the shallow tube half way up the limb. The ten stamens are about equal in length; nine of them form a continuous pallisade around the front and flanks of the ovary, the filaments being hairy for less than half their height, the long hairs interlocking, thus further barring access to the ovary in this direction. The uppermost or posterior stamen is free, being kinked below and bent backwards against the limb of the corolla; its filament, too, is hairy, but all the way up instead of only half way, and the filaments to right and left of it are rather more hairy than the remaining seven, these three posterior filaments being in close touch with the three bands of pubescence on the corolla. The isolation of the tenth stamen is neatly effected by a posterior swelling on the disc, the filament which springs from its base having to bend outwards and over the lump, thus leaving a tiny passage on either side through the staminal fence; honey is secreted by the disc, between the staminal fence and the ovary, *only* on the posterior side, and is squeezed through the two lateral ports one on either side of the posterior stamen, where it is freed from the rest of the ring fence. Finally, the short style is bent sharply down and tucked through the front portion of the fence. If this description of the structure is clear, the *modus operandi* is easily followed. We have a flower (1) in which insects (in all probability bees), or birds, are lured by marks to a particular spot, where they can find honey; (2) in which stamens and pistil are kept well apart. The three posterior stamens trail their pollen chains over the pubescent bands, where they are entangled, and where insect or bird, seeking honey at the base of the posterior stamen, cannot fail to pick them up. The first object presented to any visitor, however, is the butt of the stigma projecting through the pallisade in front—for, remember, the flower stands in the vertical plane; so if everything functions properly, cross-pollenation must result. Finally, it is possible, although of this I have no proof, that if the cross fails, the anterior stamens may drop their pollen chains on to the languishing stigma beneath, which is, at any rate, directly in their way. *F. Kingdon Ward.*

PROBLEMS OF PLANT LIFE.

I.—Do Plants Possess Nerves?

The intensive study of plant-life is calculated to develop a feeling of reverence and wonder. He who is on most intimate terms with flowers and trees often feels that he must, like Moses by the Burning Bush, remove his shoes from off his feet. The place is holy ground. The mystery of the "Bush which burns yet remains unconsumed" is but a symbol of all life's mysteries, alike in the vegetable kingdom and in the animal. One comes to share the view of Wordsworth who held that every flower enjoys the air it breathes. To treat even a bloom from the hedgerow ruthlessly seems to be an act of sheer brutality. Life is a sacred thing, even although it be but the life of a Daisy; and he who cultivates a feeling of reverence for a thing so full of mystery has partaken of something that is sacramental. Tenderness nurtured in the garden will be reflected in the home; he who loves his plants would hardly be harsh to his children, and he who stands by in reverence at the sight of an opening bloom will be likely to treat his fellow men with courtesy and respect.

As the result of recent research, many new facts in relation to the life of plants have been brought to light, and it may be of interest alike to the practical gardener and to the student of theory, if I devote a paper or two to the more interesting and important of these results. It often happens that an investigator alights upon a fact which suggests a new line of thought which for one reason or another he is unable to follow out. He makes a passing reference, suggests what he thinks might be discovered if the subject were pursued, and thus sows the seed which sooner or later may germinate and bear fruit in the life-work of another student. Almost every great discovery has been foreshadowed more or less dimly or clearly long before it has been really made. Ages ago men held that plants sometimes acted as if they had reasoning powers. They responded to various stimuli, were capable of acting intelligently, showed a determination to act in a given way when attempts were made to force them against their will, and were even held to manifest a sympathetic relationship towards human beings, so that they drooped and died if their patrons were taken ill, or revived when health and prosperity abounded.

All this might be regarded as utterly unscientific, and was put down as folklore; but as observation became more exact, and experiments were brought to bear, facts emerged which led scientific men to think that plants did indeed possess powers akin to those of animals, and might even be endowed with nerves. Perhaps their heart-beats might be counted, their pulses felt, their reasoning powers studied, and a new psychology built up as the result.

One of the first biologists to give these ideas expression in scientific form was the famous Swedish chemist Berzelius (1779-1848). In his laboratory at Stockholm he was able to carry out some investigations which were in after years to bring him world-wide fame. His chemical researches, however, led him on to the study of the phenomena of life, and he argued thus:—The phenomena of animal life are distributed between two systems, the more important of which is represented by the nerves. The conditions which enable the animal to live depend on the other system, for which he had no definite term.

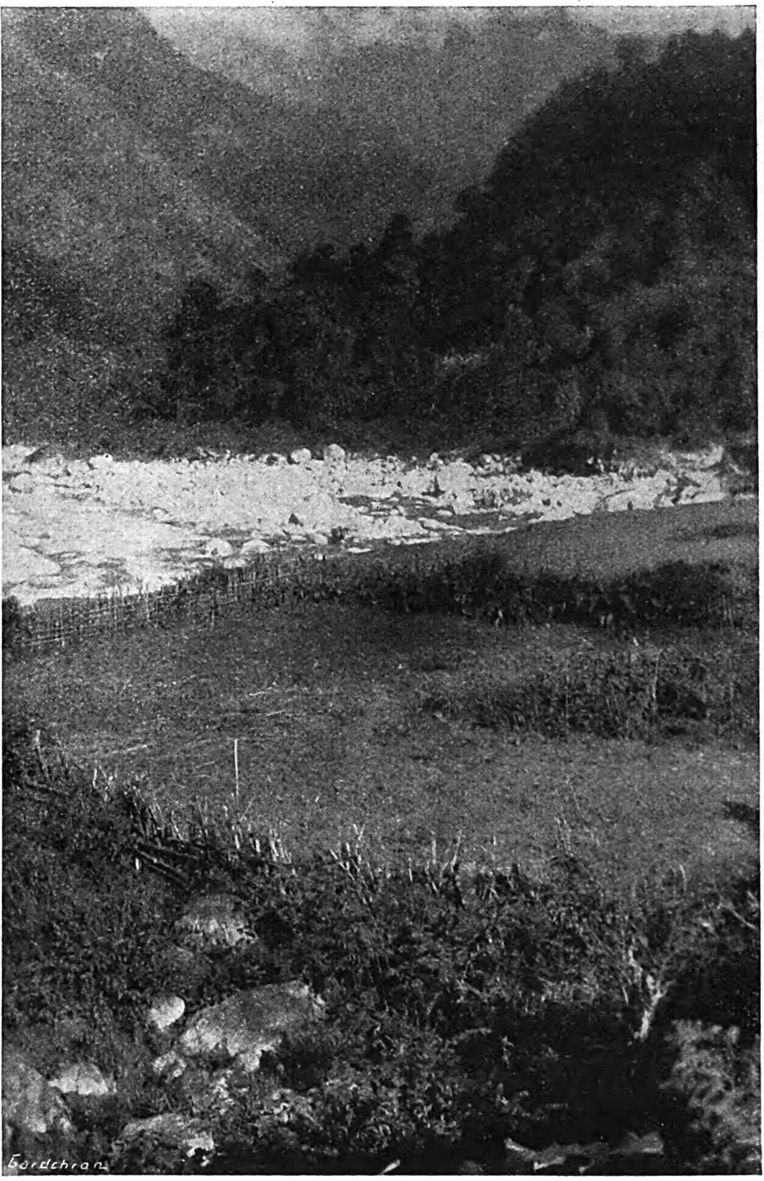

FIG. 145.—TROPICAL FOREST IN THE DELEI VALLEY.

Now the same system sets forth the difference between the organic and the inorganic. The inorganic is destitute of nerves, the organic is endowed with them; and since plants are organic they, like animals, must possess a nerve-system. This system, however, was still unknown. We may find a serious flaw in the logic if we are so disposed, but our business is to show that this careful biologist was convinced that plants had nerves. Berzelius hesitated to state what were the functions of the nervous system, and had a horror of theories and hypotheses. He was content to observe and study the facts of life and leave their interpretation unattempted until fuller knowledge enabled the student to see their meaning and purpose. The position is commendable, but one may be too conservative; and everyone is aware that while a false theory may do immense harm, much good has resulted from adopting an hypothesis as a basis for further research.

Berzelius, then, about the beginning of the nineteenth century, advanced the idea that because plants were organic they must be in possession of a nervous system. At the beginning of the twentieth century this idea was taken up in earnest, and made the subject of most careful experiment and investigation. How far Sir J. Chunder Bose was influenced, directly or indirectly, by Berzelius' views we cannot tell. He makes no reference to his great predecessor in the fascinating account of his researches which he has recently published under the title *The Motor Mechanism of Plants*, but we must not on that account withhold from the former his due.

In the volume I have just named the famous founder of the Bose Institute in Calcutta summarises the results of his researches on the movements of plants which have been appearing from time to time during the last twenty years, and we have here not only reference to the visible external movements which occur naturally or under the action of various stimulants in the laboratory, but also to the invisible internal movements which are constantly going on, as, for instance, in the propulsion of the sap. This really remarkable volume, which is very fully illustrated, shows that the mechanism of plants is exceedingly complex and wonderful. By experimenting in the first place on such responsive plants as the Mimosa and Desmodium—plants which have for many years claimed a large amount of attention on the part of botanists and biologists—he was able to push his investigations into other fields, and show what he calls the heart-beat of a plant by means of the rhythmical contraction of the cells. By the use of drugs, plants are made to droop or revive exactly as would any patient in the animal world. Changes of heat, light, moisture and electrical discharges were used with amazing effects, and we have the author's assurance that his results have been confirmed by scientific authorities whose credentials are beyond dispute.

The net result of Sir Chunder Bose's researches may be stated to be that there is no physiological line of cleavage between animals and plants. The volume is therefore at once a testimony to the truth of evolution, and a particularly valuable aid to the study of animal and human—so well as of plant—physiology. Experiments on men and dogs, even in the interests of human well-being, may be regarded by some as unjustifiable, and vivisection will always have its opponents. There can, however, hardly be any objection at present to the use of plants for experiments intended to determine the nature of the nervous system, the mechanism by which movement is directed, and the methods by which life is maintained and rendered effective. I think it may safely be conceded that some plants at least possess nerves. That they are in every respect like our own is, however, not to be admitted so readily. *Hilderic Friend.*

(*To be continued.*)

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

A rough estimate may now be formed of the injury inflicted upon trees and shrubs by the rigours of the past winter. The full extent of mischief among herbs will not be apparent until later. It is remarkable that, although in this maritime district no more than 12° of frost was registered, many shrubs which had passed unhurt through far lower temperatures in former seasons have been badly disfigured, and in some cases killed, in this one. This seems to be the result of the long duration of frost, accompanied by violent east and north-east winds in February. Several species of Cistus have been killed outright. Even C. cyprius and C. laurifolius, which I have never known to be injured in former years, have had their foliage browned where exposed to the wind. Much havoc has been wrought upon some varieties of Veronica speciosa, but V. Traversii and V. salicifolia remain unhurt. Drimys Winteri and Genista hispanica are severely scorched, but will recover; the foliage of Tricuspidaria lanceolata is discoloured in places, but the flower buds, which I have known to be destroyed in former winters, remain quite fresh. Eupatorium Weinmannianum seems past praying for. Tall plants of Myrtus Luma have been disfigured where the wind caught them, which I have never known happen before. Senecio Hectori is a very sorry sight, its great leaves hanging lifeless, but they will be replaced from the young buds which are still fresh; and Senecio Huntii has suffered no harm. Large bushes of Hypericum patulum have been badly cut, but the varieties Henryi and Forrestii remain unhurt.

Among shrubs of more or less doubtful reputation for hardiness, the following have suffered no injury whatever in the open ground: Desfontainea spinosa, Pieris formosa, Leptospermum scoparium (with its variety Nichollii), L. ericoides and L. pubescens, Rhaphiolepis japonica and R. Delacouri, Abutilon vitifolium, Lomatia ferruginea, Eucryphia cordifolia and its Nymans hybrid, Olearia semidentata, O. nitida and O. insignis, Gaya Lyallii, Cordyline australis, Styrax Obassia, S. Helmsleyanus and S. japonicus, and Griselinia littoralis; the last-named is really remarkable as a vivid evergreen, never flinching from the blizzard.

So much for shrubs in the open. Among those against walls Feijoa Sellowiana is badly discoloured; next to it on one side, Helichrysum rosmarinifolium seems defunct, while on the other side Billardiera longiflora remains quite happy, having carried its shining purple fruits right through the winter. Myrtus communis is a sorry sight, but is not seriously hurt, and the same may be reported of Abelia floribunda; both having suffered from cruel winds. Two plants of Rhodoleia Championi were killed in the open during the winter of 1927-8; but a third remains quite vigorous on a south wall, having been protected by a screen during the frost.

Among Rhododendrons, we have no losses to record; indeed, the prolonged cold has proved a protection to those species which are dangerously prococious in growth. The promise of flowers on most Rhododendrons is indifferent this year; R. decorum, R. oreodoxa, R. Fargesii, with the "Triflorum" and "Heliolepis" series being notable exceptions.

If these notes should catch the eye of a lady who, in her bounty, sent me some Gloxinia tubers about a month ago, will she kindly understand that the only obstacle to my returning thanks for the gift direct is that the letter which accompanied it did not reveal her address. *Herbert Maxwell, Monreith.*

SOME APRIL-FLOWERING ANEMONES.

That delightful plant, Anemone blanda, has been so retarded this season that it is only now (early April) coming into its best. This means that instead of being over before the A. nemorosa clan and others make their appearance, it has added the charm of its peculiar brightness to the main display of the woodland Anemone season. A. blanda is such a delightful thing in all its forms that one hesitates to make comparisons between the latter, but the dark blue, almost violet, varieties are especially appealing. A. b. var. scythinica, with white flowers stained on the reverse with deep blue, is also distinct and choice, and then there is A. b. var. rosea whose long, narrow rays are a fresh pink. In striking contrast to some groups of these in a sunny woodland corner is A. Seemannii (intermedia). This, I am told, is a hybrid between A. nemorosa and A. ranunculoides. It is an Anemone of much daintiness and the finely-cut foliage, being a deep bronzy-green, makes an attractive setting for the delicate loveliness of the soft primrose-yellow flowers

If the blue forms of A. nemorosa do not attain the intense brilliancy of A. blanda, they are not less enchanting in their tender shades of lavender-blue, in which direct sunlight will nearly always betray a hint of pink. A. n. var. Allenii is still, I think, the best of these blues. It is an exquisite subject for a partly-shaded woodland retreat, the conspicuous wreath of yellow anthers being in delightful harmony with the blue of the broad sepals. All of this class, of course, have their golden centre, which is so effective, and A. n. var. Robinsoniana, another large-flowered one, rivals the above in its gracious beauty, as well as in size. Still bigger in the blossom is the later, A. n. var. Blue Bonnet, with enormous, clear blue-lavender flowers of wonderful substance, and there are many others, not forgetting the little, pale-blue and rosy Welsh forms of the wild type which are plentiful in some mountain pastures and not less entrancing in the woodland garden. A. n. var. alba plena, a double-flowered development, is always worth a choice place, as is A. n. var. bracteata plena with its double white blossoms and curious green bracts.

Of the same kinship as the above is A. trifolia, and among the white-flowered dwarf Anemones I know of none more useful and pretty than this little European alpine. It grows about eight inches tall, and its bright green leaves, which are broader and less cut-up than those of our native Wind Flower, afford an attractive setting for the firm, milky-white stars which are about an inch across. Growing in dense colonies and naturalising freely, this species is one of those happy plants which take care of themselves and carry-on indefinitely, gathering increasing beauty year by year.

A. ranunculoides, which appears to be allied to A. nemorosa, is also a European sub-alpine with an attraction of its own. It does not exceed four inches in my light loam, nor does it spread with the hearty vigour of the preceding. But it is a dainty little plant with flowers of a good yellow, and there is a semi-double variety. This species, like most others, varies considerably in size and colour, so that it is always worth while looking-out for forms which have broken away from the family tradition and developed a quality of their own.

Some seedlings of A. Pulsatilla, the parent plant having flowers of a rich violet-purple, are giving an attractive assortment of colours ranging from a washy lavender to deepest violet, and from a pale lilac to a rich blood-crimson. These all do well in very poor soil, mostly stones and grit, and under such conditions even our humid westerly winters are not resented. Yet A. Halleri, with similar treatment, cannot be relied on as a permanency, nor can the elusive A. P. var. Mrs. van der Elst. A. sylvestris is another spring-flowering species which has been a disappointment. It is perfectly easy to grow in some gardens, but will not be comforted in this one, no matter how ideal the soil and position may seem.

A. vernalis is the trump card of these April Anemones here, and it is as good (in dry moraine) as it is beautiful. Long-lived, perfectly hardy, pest-proof and endowed with a dozen more excellent qualities, the "Lady of the Snow" is a plant of strange and magnetic attraction. Perhaps the flat rosette of bronzy, rather weedy-looking leaves may to some extent serve to emphasise the peerless beauty of the flower, but the latter has an intrinsic loveliness which no accident of contrast could embellish or defeat. The tawny, iridescent fur which envelops the stem and backs the outer parts of the sepals is more vital and colourful than the shaggy silk of A. Pulsatilla, the inside of the chalice more chastely beautiful with its shell-gleam whiteness and eye of gold. This arresting plant, high alpine that it is, does not only flourish year in and year out with the best of goodwill under cultivation, but it sets any quantity of seeds. These, moreover, are easily germinated, and the seedlings demand no special care.

Among the many other April Windflowers which might be mentioned here, A. apennina is one that cannot be omitted. This is a very precious species for the woodland or grass land, since it naturalises so freely under favourable conditions, and there is nothing lovelier in the spring garden than its brilliantly blue, Daisy-like flowers in association with Daffodils and Primroses. Although A. apennina takes so willingly to our climate that it has made some claim to be regarded as an adopted member of the British flora, it does not do well in my shaley loam. This is probably more the fault of dried tubers than of the plant itself, and I am cherishing the prospect of some day being able to get it agoing by planting the active roots before the foliage disappears in early summer. *North Wales.*

DISEASES OF GRASSES.

Some Observations on Epichloe typhina, (Fr.), Tul.*

Epichloe typhina (Fr.), Tul., is an Ascomycete fungus which causes a disease of wild and cultivated grasses. The popular name "choke" aptly describes the symptoms. Early in May, infected plants show white patches of mycelium and conidia on the largest tillers. These tillers are potentially fertile, but the panicle fails to emerge since the enclosing leaves of the shoot are firmly bound together by strands of mycelium. Infected plants are often completely barren by reason of the "choke" disease. The disease is therefore of first importance when grasses are grown for the purpose of seed production or for experimental study. A large collection of different strains of Cocksfoot (Dactylis glomerata) growing at the Welsh Plant Breeding Station, Aberystwyth, has suffered severely, over fifty per cent. of the plants being attacked in 1927.

---

* Abstract of a paper by Miss K. Sampson, read before the British Mycological Society on March 16.

During the summer, the colour of the fungus changes from white to yellow, and finally to brown, the mycelium mass thickens, and perithecia are developed. The thread-like ascospores are shot out and are capable of immediate germination. By the end of August the perithecial stroma dries up or decays, and until May comes round again the plant shows no external symptoms of the disease.

Microscopical examination of the leaves and stems during the winter months reveals the slender, septate mycelium of the fungus running between the cells. It is not surprising to find, therefore, that vegetative propagation of the host results in a multiplication of the parasite. One experiment carried out at Aberystwyth may be quoted. An infected plant of Cocksfoot was broken up in order to give the greatest possible number of new plants. Among the 287 plants which were produced, only one was found in the following season to have escaped infection. This shows how extremely wide and uniform is the distribution of mycelium in the host.

Red Fescue (Festuca rubra) is included among the eight species of Gramineae which have been from time to time attacked by "choke" in the neighbourhood of Aberystwyth. It has received special study because it presents certain features which are of peculiar interest. In this case the panicles are only rarely trapped in the sheath by the fungus. Normally they emerge, and frequently they carry aloft the white conidial stromata. A single infected plant often produces fertile tillers with trapped panicles, panicles which are exserted but are wholly or partly destroyed by the fungus, and others which show no visible sign of attack. Seeds were collected from several plants of this type in 1923 and 1924, and families including in all over a thousand individuals have been under observation during the past five years. Every family which came from an infected female parent showed a considerable amount of the disease, the number of individuals attacked by Epichloe varying in the different families from eighteen to ninety-six per cent.

Microscopical examination has again revealed the parasite in the vegetative organs. Typical slender intercellular mycelium has been traced from these up the flowering stem and into all parts of the flower. It has been found in the pales, the filaments and anthers, the ovary wall, the integuments, and in the nucellus of the ovule. Mycelium is abundant in the ripe grain of infected plants, occurring for the most part immediately outside the aleurone cells. It occurs frequently round the embryo, and it has been seen in the first leaves of seedlings germinated in the laboratory, and in the older seedlings grown outside in experimental plots.

It is evident, therefore, that when Epichloe typhina occurs on Red Fescue it can be transmitted by infected seeds. The experiments indicate that infected plants rarely produce individuals which are free from the infection, although external symptoms of the disease may not be developed for several seasons in succession. In other words, it is possible to find a plant of Red Fescue which is superficially quite healthy, but which, under the microscope, is found to be invaded by mycelium. A plant of this type suggests a close and interesting parallel to the endophytic fungus of Darnel (Lolium temulentum).

In conclusion, it may be stated that Epichloe typhina is undoubtedly a parasite. In addition to the wholesale destruction of the inflorescence, the adverse influence of the fungus on Red Fescue is shown in the number, weight and viability of the seeds produced by infected plants. The influence varies in intensity from plant to plant, but it is evident not only in plants showing visible symptoms of the disease, but also in those which contain only the hidden mycelium. *J. R.*

NOTICE OF BOOK.

A Book on Lilacs.

In a key to the species of Syringa contributed to this work* by Mr. A. Rehder, he admits twenty-eight species. It is not often that a genus of this size, of almost purely horticultural interest, and presenting no special botanical problems or cultural difficulties, has had devoted to it a volume so large and so sumptuous as this. Mrs. McKelvey must be complimented on having done her work with absolute thoroughness. The mere references for instance to the first species with which she deals, S. Emodi, fill more than a quarto page; the whole discourse on it occupies ten pages, and is illustrated by five full-page plates. The article on S. Josikaea fills thirty pages. It follows that every aspect of the genus Syringa—historical, botanical and horticultural—has been fully explored, and it is difficult to imagine that anything further of value remains to be written about the species and varieties known to exist at the present time.

The genus as a whole is clearly divisible into two main groups. The first is the section Ligustrina, or Privet-like Lilacs, which consists of three species—S. amurensis, S. pekinensis and S. Fauriei. (The shrub or small tree we have known and cultivated in this country as S. japonica is, in this work, reduced to a variety of S. amurensis). They have small, Privet-like, white flowers, the tube of whose corolla is shorter than its lobes. The second and more important section consists of the true Lilacs (Eusyringa), whose flowers are mostly lilac, pink or purple, and whose corolla has a tube much longer than its lobes.

The true Lilacs are again divisible into two groups, one of which is typified by the common Lilac, S. vulgaris; in this the shoots do not form a terminal bud, and the leafless flower trusses come from lateral buds of the previous season's growth; the other, represented by S. Emodi, S. Josikaea, etc., produces its flowers from a terminal bud on a panicle leafy at the base.

Mr. E. H. Wilson contributes a chapter on the history and distribution of the genus, and gives, in particular, a very interesting account of the Persian Lilac whose real home, he informs us, is not Persia, as the specific name would imply, but the Chinese province of Kansu, a region "traversed by one of the great highways which the ancients used to journey across the heart of Asia." It was by this highway that the Persian Lilac is assumed to have reached Persia.

The great bulk of the book we owe to Mrs. McKelvey's wonderful industry. What it must have cost her in time and patience it would be difficulty indeed to calculate. She has apparently searched every botanical and gardening book of any standing that has been written in English, French, German, Italian and Latin, and extracted from them everything of botanical and horticultural interest concerning her subject.

Of the common Lilac and its history she gives a very fascinating account, and of apparently every one of its numerous varieties a description and history, so far as it could be ascertained. To it alone nearly two hundred pages have been devoted, sufficient in itself to constitute a volume of moderate size. A chapter on cultivation and forcing is contributed by Mr. T. A. Havemeyer, and one on diseases and insect pests by Dr. W. T. Councilman.

The book is illustrated with one-hundred-and-seventy-two full-page plates, the majority of them process reproductions of photographs taken in the Arnold Arboretum, where the collection of Lilacs—both species and varieties—constitutes an admirable and prominent feature. Of many species, five or six figures are given representing the winter buds, the expanding buds, the flower truss and foliage, and the entire plant in blossom, fruit, and bark. With all this, Mr. Rehder's key and the author's very full descriptions, it must surely be a dullish intellect that fails to distinguish any species in cultivation. In order that the colour descriptions may be correctly appreciated, Mrs. McKelvey has provided four colour charts based upon Ridgeway's *Colour Standards and Colour Nomenclature*. When, therefore, the student encounters such colour terms as "vinaceous purple" or "chalcedony yellow" he is able by reference to these charts to ascertain the identical shade meant.

We can only conclude by congratulating the author on producing a work of such learning and infinite research which is likely long to stand alone and unapproachable as an example of completeness in a monograph of its kind.

THE GENUS PRIMULA.

(*Continued from p.* 266.)

MERRILLIANA (Schltr.). Merrill's P.
(Pinnatae.)

A REMARKABLE, deciduous, perennial species with a rosette of thin, smooth leaves, one-and-a-half inch to two-and-a-half inches long, including the stalk, with pinnatifid blades like those of a Carrot; the numerous lobes are oblong in shape, more or less oblique, and edged with coarse teeth or small lobes. Flower stem erect, slender, slightly downy, two-and-a-half to four-and-a-half inches tall, bearing an umbel of two to five blossoms, on short stalks sparsely clothed with fine hairs. Corolla tubular, about half-an-inch long, divided almost to the middle into five broadly oval, blunt, slightly oblique lobes about a quarter-of-an-inch across; tube cylindrical below, dilated above the middle, about a quarter-of-an-inch long. Not in cultivation.

This species is a native of Anhwei, in eastern China; the colour of its flowers and the conditions under which it grows have not been recorded.

Culture: Conditions as for P. Filchnerae would probably prove suitable.

METRIA (Balf. f.). Pumthang P.
(Soldanelloideae.)

A dainty, low-growing perennial species with small rosettes of oblong, oval, elliptic or nearly heart-shaped leaves, blunt or rounded at the tip, abruptly or gradually contracted into a wedge-shaped stalk, in all from one to one-and-a-half inch long; margins furnished with rounded, regular teeth; both surfaces densely covered with minute, jointed hairs. Flower stem about two-and-a-half inches tall, downy, bearing a short, erect, capitate spike of pale blue or white, deflexed, stalkless flowers. Corolla about five-eighths-of-an-inch long, funnel-shaped, divided to the middle into five wedge-shaped, truncate, slightly cleft lobes, internally covered with minute, glandular down; tube cylindrical, about a quarter-of-an-inch long, smooth outside, downy within. Flowers in June.

Grows in damp, shady places in Bhutan, in the eastern Himalayas, in Champa Pumthang.

Culture: Peat, friable loam and sand, in a cool, shady spot, with protection from damp in winter, are indicated.

MEYERI (Rupr.). Meyer's P.
(Vernales).

This desirable deciduous perennial is a subspecies of P. amoena (Bieb.). It produces a tuft of more or less oval leaves two to five inches long, blunt at the tip, almost heart-shaped at the base, abruptly contracted into a winged stalk; margins edged with blunt, rounded, regular teeth; upper surface smooth, underside at times hairy on the nerves. Flower stem three to seven inches tall, bearing one to three reddish-purple blossoms. Corolla about three-quarters-of-an-inch across, with broadly oval, lightly notched segments; tube cylindrical, about five-eighths-of-an-inch long.

---

* *The Lilac*, by Susan Delane McKelvey. 1 Vol. 4to. The Macmillan Co., New York. Price £3 15s. nett.

Grows in cool, shady places in the central and western Caucasus, at 6,000 to 12,500 feet above sea-level.

Culture: Fibrous loam, leaf-soil and sharp grit, in a cool, moist but well-drained spot, are the conditions required.

MICRODONTA (Franch.). Moonlight P. (Sikkimensis.)

A very beautiful, deciduous species exceedingly variable in the tinting of its blossoms. The short rootstock produces a rosette of almost smooth, somewhat leathery leaves with broadly oval blades, gradually tapering to long stalks, in all two to nine inches in length; margins toothed. Flower stem from nine to thirty-six inches tall, bearing one, or from two to four superposed umbels of fifteen to twenty, usually nodding, very fragrant blossoms varying from pale yellow to white, sometimes tinged with violet, and powdered with white meal in the throat. Corolla about three-quarters-of-an-inch across, with rounded, notched lobes; tube funnel-shaped, much longer than the calyx. Flowers in July and August.

Grows in shady bogs and on the margins of mountain streams, in south-eastern Tibet, at 11,000 to 12,000 feet above sea-level.

Var. alpicola (W. W. Sm.). Plant twelve to eighteen inches tall, flowers pale primrose-yellow, dusted with white meal in the throat, fragrant. Flowers in June. South-eastern Tibet, Temo La, at 13,000 to 14,000 feet.

Var. alpicola forma micromeres (W. W. Sm.). A high alpine form with sulphur-yellow, fragrant blossoms. Flowers in July. South-eastern Tibet, Sang La, at 14,000 to 15,000 feet.

Var. alpicola forma violacea (W. W. Sm.). Plant twelve to twenty-four inches tall, flowers violet-purple or wine-coloured, powdered with white meal in the throat, very fragrant. Flowers in June. South-eastern Tibet, Nyima La, at 12,000 to 14,000 feet.

Culture: Good rich loam and peat, and treat as bog plants when in growth. *A. W. Darnell.*

(*To be continued.*)

ORDER OF FLOWERING AND POLLENATION OF FRUIT BLOSSOMS.*

The object of this paper is to show that observations of fruit blossoms and their insect visitors may be used as a guide in orchard planting and in the increase of the crop of fruit.

It is granted that many things are necessary in order to secure a good and profitable fruit crop; one naturally thinks of the need for healthy trees, efficient drainage, suitable soil, proper cultivation, freedom or protection from diseases and insect pests, kindly weather, especially at blossoming time, and, lastly, a remunerative market.

Botany, however, teaches us that the pollenation of blossom is well worth careful and thoughtful study, as without fertilisation fruit is not produced.

By pollenation is meant the transference of pollen grains from the anthers to the stigmas; the pollen grain there germinates, throwing out a pollen tube which travels through the style to fertilise the ovule, which then becomes a seed, around which the fleshy fruit forms.

Agricultural and horticultural research has devoted much of its energy to explaining why many good practices which have been long in existence are right (liming, for example). Our forefathers planted orchards of mixed varieties, whether it was of Apples or Cherries, and kept bees; recent research on fruit pollenation has proved that both were good practices.

The Arabs, certainly so far back as the time of Mahomet, cut pollen-bearing branches from the male Date Palms, carried them up the fruit-bearing trees and tied them among the branches for the wind to distribute the pollen. The Turks must have long known that without a certain little wasp they could not get a crop of Smyrna Figs. Probably neither the Arab nor the Turk would satisfy the botany examiner of London University as to his knowledge of fruit pollenation, but observation and experience have taught each a great deal, and it has been left for recent years to explain the facts in botanical terms.

In growing our common English fruits we get examples of wind and insect pollenation; self and cross fertilisation.

WIND POLLENATION.

Cob and Filbert Nuts, and Walnuts, each produce dust-like pollen which is carried by the wind to the female flowers; in each of these botanical observation has something to teach. To ensure a crop it is necessary that the pollen be shed at a time when the stigmas of the little Nut flowers are receptive. The catkin-bearing branches must not be pruned off before the Nut flowers are fertilised; some varieties do not bear many catkins, and in other kinds the time of pollen shedding and opening of the female flowers do not synchronise, so that it may be advantageous to have a few trees of another variety to assist the pollenation. The late Mr. George Bunyard recommended planting an occasional Cosford Cob through the Nut plantation, it being a variety that bears many catkins. Professor E. J. Wickson, of California University, has shown that for growing Walnuts commercially it is advisable to interplant several varieties, as in some sorts the pollen is shed too early or too late for the female flowers on the same tree. In the garden of an uncle at Sheldwich, Kent, there were two Walnut trees standing about ten yards apart; one was a soft-shelled Walnut, the other a hard-shelled form; he kept an account of the yield, and in twenty-nine years the trees bore 330 bushels of Nuts, which sold for £66 10s. (besides some kept for the house). I believe the good and regular yield was due to the fact that they were different varieties and cross-pollenated one another efficiently.

INSECT-POLLENATED FRUITS.

The Strawberry is pollenated both by wind and insects. Raspberries and Loganberries are self-fruitful and mature fruit perfectly with pollen of the same plant, but they need insects to carry the pollen. If insects are excluded from the blossoms, the fruit is imperfect and deformed. Hive bees are very fond of Raspberries, they undoubtedly increase the crop, and the Raspberry is one of the best plants for honey production.

Gooseberries, Red Currants and Black Currants all mature fruit perfectly with pollen of the same plant, but their pollen is glutinous, like minute grains of boiled sago, which clings together and cannot be transported by the wind, so they are dependent on insects to carry it from the anthers to the stigmas.

Where a large acreage of Gooseberries or Black Currants is grown, there may not be sufficient wild insects to visit the blossoms, and growers find that by placing hives of bees in their plantations they get more fruit.

FRUIT TREES.

In fruit trees, profuse blossoming does not necessarily foretell a large crop; weak trees sometimes flower excessively to the disadvantage of maturing fruit. Super-abundance of flowers apparently wastes energy.

In the case of Apples, Cherries, Pears and Plums it is found that the blossoms are practically entirely dependent on insects for fertilisation; experiments show that wind carries very little of the pollen from flower to flower. In these fruits a new factor comes in, viz., that a large number of the varieties will not mature fruit when pollenated by pollen of the same variety. A new variety is originated as a seedling and is propagated by budding and grafting on other stocks; consequently, the pollen is similar, whether it comes from the same flower, the same tree, or another tree of the same variety, although it may be growing at a distance.

Self-fertile or self-fruitful are terms applied to a variety that matures a considerable proportion of its blossoms into fruit with pollen of the same variety.

Partially self-fruitful means that only a small proportion of the flowers will mature fruit with pollen of the same variety.

Self-sterile is a term applied to varieties that will mature no fruit with their own pollen, or mature only perhaps one fruit in a thousand blossoms, and is, therefore, for practical purposes, self-sterile; there are varieties of Apples, such as Cox's Orange Pippin and Lane's Prince Albert, which in many trials have shown themselves to be self-sterile, although one flower out of 2,000 may eventually mature a fruit under glass.

Of Apples grown in the open about two-thirds of the varieties appear to be self-sterile, and no variety is sufficiently self-fruitful to plant profitably in a block alone.

About half the varieties of Pears are somewhat self-fruitful, but they are relatively less self-fruitful than Apples.

With Plums, about half are more or less self-fruitful and half are self-sterile, or nearly so.

Among Cherries, Morello is perfectly self-fertile. Flemish and Kentish preserving Cherries and May Duke are to a small extent self-fertile, but the Sweet Cherry varieties are all either absolutely self-sterile, or self-fruitful to the extent of only one or two per cent. It is, consequently, not surprising that there are Cherry orchards which year by year crop badly, especially as some varieties of Cherry are inter-sterile, *i.e.*, will not mature fruit with pollen of the other variety.

As cross-pollenation is shown to be beneficial in increasing the crop, it is necessary to ascertain that the varieties which it is proposed to plant together flower at about the same time; one should avoid planting early-flowering with late-flowering, unless there is a mid-season flowering variety which will pollenate both.

It may be stated that, provided the two varieties are in flower at the same time, the pollen of one variety is as good in the production of fruit as the pollen of another variety. In the United States, however, in experiments with Apples, some varieties were found to cross-pollenate better with the pollen of one kind, than with that of another. Personally, I believe there is a difference (especially in some of the shy bearing varieties) and that a variety may bear more fruit with one kind of pollen than with that of another. I think this may be more the case with fruit grown in the open than that grown in the more congenial glasshouse.

It is interesting to find that different varieties of the various fruits flower in a definite order, in the same way as the flowers of the countryside, where the Snowdrop is followed by the Aconite, the Crocus by the Hazel, Lesser Celandine by the Coltsfoot, Almond by Wood Anemone, and so forth; in like manner the different varieties of Pear, Plum, Apple and Cherry flower in fairly regular succession. In former days orchards were planted with a large number of varieties which mutually cross-pollenated one another, but in wishing to lessen the number of varieties and in order to grow a large quantity of a remunerative variety, some orchards have been planted with one variety only, or with two varieties that do not flower at the same time or, in the case of some Cherry orchards, with varieties that do not cross-pollenate.

Careful records of the order of flowering of Apples, Pears and Plums have been kept at six or eight observation stations in Australia for several years, and these records correspond fairly nearly with those kept in England; thus Black Diamond Plum flowers early and Pond's Seedling late; in Pears, Brockworth Park flowers the earliest, with Keiffer's Hybrid, while Williams's Bon Chrétien, Marie Louise, Glou Morceau and Beurré Capiaumont flower late, showing that the order of blossoming in Australia closely resembles that in England. In Australia, many more English varieties of Apples, Pears, Plums and Cherries are grown than in Canada and the U.S.A. One wonders why European varieties of Apples should thrive better in Australia than they do in America.

(*To be continued.*)

---

* A paper read before the Royal Society of Arts, Wednesday, February 13, by Mr. Cecil H. Hooper, F.L.S., of Wye, Kent.; Mr. H. V. Taylor, O.B.E., Commissioner for Horticulture, Ministry of Agriculture, presided.

CYCLAMEN LIBANOTICUM.

I enclose a photograph (Fig. 149) of the rare Cyclamen libanoticum, of Siehe, described on p. 97 (February 9). It flowers in the months of February-March, and is very fine and fragrant.

In my former note, I forgot to mention Cyclamen maritimum, of Siehe, which is really a very fine form of C. graecum, with thick, dark green leaves, very sharply crenate-dentate. The flowers have ovate sepals and ovate-lanceolate petals, both very obtuse and even rounded. This flowers in autumn, and its colour is light rose. It was sent me by Siehe twenty-five years ago. *H. Correvon, Floraire, Geneva.*

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

The Control of Slugs.—Now that the season has arrived for the sowing of both vegetable and flower seeds, I wish to place before readers of *The Gardeners' Chronicle* my experience with regard to a British anti-slug preparation called Slug-Mort—which has recently been put on the market—in order that all may know of, and derive benefit from the use of it, as I have done. My experience was as follows. Last autumn I sowed Lettuce seeds in an early and sheltered border under a wall; no seedlings appeared. Upon investigation, I found the ground was full of slugs, which had penetrated the soil and devoured the seedlings immediately after germination. I then proceeded to make a second sowing, at the same time smothering the drills with Slug-Mort, mixed with bran in somewhat stronger proportions than advised in the directions, raked the soil level, and scattered more of the mixture on the surface. The result was a ninety-per cent. germination, and the crop grew away without any further attack from the slugs and no harm whatever to the vegetation. I have also used this preparation most successfully on Chrysanthemum stools in frames, the shoots of which were eaten off as fast as they grew. This exterminator evidently fills a long felt want and could, with advantage, be used in every garden and nursery in the country, as, besides being most inexpensive, it can be applied with safety, and a minimum of labour, large areas being covered at small cost. I am in no way connected financially or otherwise with the vendors of this article, but having found a really good thing, I think it only right that my fellow horticulturists should have an opportunity to share my knowledge of its efficiency, whereby valuable crops can be saved from destruction at an expenditure of a few shillings. *J. Muir.*

Storing Vegetables.—The severe weather recently experienced will long be remembered for the damage done to all growing crops, such as Broccoli, Savoys, Cabbages, etc. In this district, Evesham to Tewkesbury, the acreage of market gardens is very considerable, and here one may see the damage done and the loss entailed. It is really very pitiable to see the large fields of Cabbages which, under normal weather conditions, would have been fit for market, now looking, as the phrase goes, "like a hay field." In a good many cases the losses are from fifty per cent. to eighty per cent. killed; this means, of course, a great shortage of food. In November and December there was a glut of all vegetables. I know of acres of Savoys which were fed to sheep, or even ploughed in, because there was no market, and yet, in London shops, prices for these were high. If only there were better facilities for the growers to supply the consumer, or if there could be more control, and the profits better distributed, then the grower would work for production with the knowledge that he was able to pay his way. I have had considerable experience, including twelve years in Sweden, of storing all kinds of vegetables, and I consider it expedient to practice at least a part of the storing process in this country of fluctuating season and climates. Take, for instance, a late crop of Cauliflowers. If they were lifted and laid in thickly and covered with any light material, such as spoilt hay or straw, their season would easily be prolonged until December. Broccoli could also be lifted and treated in a somewhat similar manner, but with more protection, taking care to protect the stems. Dry leaves and Bracken would be ideal for this purpose, and—when obtainable—much cheaper. This lifting may seem unreasonable, but in private gardens where only a few hundreds are grown, it could be practised with ease and prove economical, and instead of having nothing except half-spoilt Greens, a regular supply of good vegetables would be maintained. Savoys may be cut and, when sufficiently dry, stacked or pitted in the same way as Mangolds, and will keep for a couple of months if not allowed to heat. Surely this would be better than allowing them to stay in the field or garden to rot, as was the case this season. I may mention here that another good point in this method is that the ground can be prepared for the next crop. It may be suggested that such sharp winters only come at long intervals, and the question asked—Why go to all this trouble? My answer is, that, like wars, they come, and it is good to be prepared. Not only the green crops, but also very large areas of Peas and Seville Beans are, or have been, ploughed in; this is very serious for the grower, who has been depending on these crops for existence, and the consumer will feel the pinch later on. *James Page, Showborough Villas, Strentham, Worcester.*

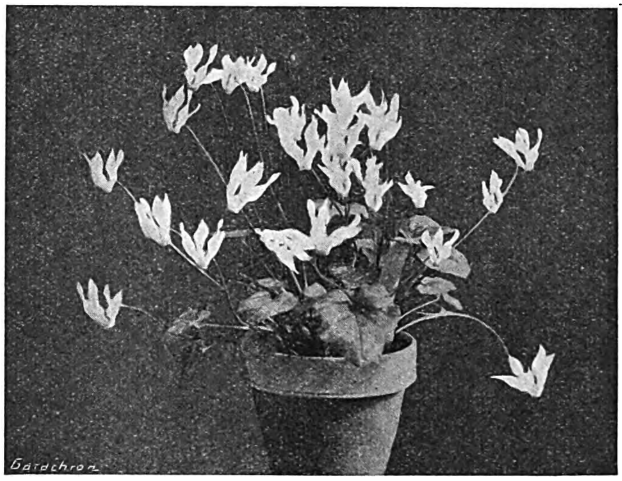

FIG. 149.—CYCLAMEN LIBANOTICUM.

Salix lanata var. Stuartii.—(See pp. 60, 107, 159, 208 and 231). Mr. J. Blades has introduced another Willow in discussing the origin and name of the above, namely, Salix Stuartiana, but that being well authenticated by figures and descriptions, there is no difficulty in explaining what it is. Sir James Edward Smith first described it as a species in the *English Flora*, p. 203 (1830). It is also figured in *English Botany*, tt. 1809, 2586, and in the second edition of that work, t. 1355. He had it from Rev. Dr. Stuart, who found it in the mountains of Breadalbane. This same gentleman sent several Willows to Smith, and I believe he was a son of the Rev. James Stuart, minister of Killin, Breadalbane, who died at the end of the eighteenth century. The son would therefore be familiar with Breadalbane. The same Willow was collected by Mr. W. Borrer at the upper end of the Finlarig Burn, a matter of two miles from Killin as the crow flies. Mr. D. Turner collected it on Ben Lawers, eight miles from the village. I collected it on Ben More, ten miles from the village. The botanist Griselin sent a specimen of it from Siberia to Linnaeus. The Willow in question is a very small, woolly-leaved form of S. lapponum, which I have labelled S. lapponum var. Stuartiana (Sm.) out of compliment to Smith. His S. arenaria was simply a greener, less hairy form of S. lapponum. These two so-called species are merely forms of a very variable Willow not now maintained. That is why Dr. Moss calls S. Stuartiana a synonym of S. lapponum. The S. lanata × lapponum referred to by him was the plant discovered and described by the Rev. E. F. Linton, and published in 1913. S. lanata var. Stuartii is a third Willow in the case, and is stated on good authority (p. 159) to have been originated by Dr. Stuart, of Chirnside, Berwickshire, who flourished in the 'nineties of last century. *J. Fraser.*

Rewards and Other Things.—If I were to exhibit at Westminster six vases, each containing twelve perfect flowers of a variety of Calendula or Tagetes, I might, if lucky, obtain a Banksian Medal, but if I had ten times as many of the same flowers nicely set out in "art" vases on black velvet, with "Asparagus Fern," I should probably get a Gold Medal. An exhibitor asked me "How can I secure a Silver-gilt Banksian Medal for my alpines?" My answer was, "You must have twice as many plants in twice as many varieties, and must introduce more richly coloured forms." And Violets! Their humility is at once their reward and their undoing. Orchids are a class to themselves and obey no law, with this exception, that the R.H.S. fortnightly meetings and other shows constitute the market where nurserymen display their wares for sale—wares cared for like Mr. Cochran's "young ladies." After all, the nursery is the best place in which to buy plants, and next to the nursery, the catalogue in the study. At a show, the perfection of the protected blossom is the snare into which one is led by the enthusiasm of your boy or girl friend. Nowadays, at shows, the exhibits are largely ordinary stock, plants which can be supplied in any quantity. New, rare, noteworthy and uncommon plants are naturally not shown by the trade until a sufficient stock has been worked up to supply orders. From 1830 to 1880 it was otherwise, because in the first place plenty of good plants were being discovered and, secondly, there was a limited demand. Something should be done to encourage the amateurs to show new and rare plants. The two-day show is a real difficulty to the private grower. He has the cost of a van for two days instead of one; he is deprived for a similar period of the services of his gardeners. Then, having sent up a collection of forty or fifty rare plants, he may, if fortunate, receive a Silver-gilt Medal, while the Gold Medal goes to Messrs. Cartons' 120-feet run of Balsams and Viscarias! Why do we never see exhibits from foreign countries? Orleans, Angers, Ghent, Bruges, Hanover, Erfurt, and Naples are towns where any day of the week one may meet the English retail or wholesale nurseryman looking around. But if Messrs. Barmorin are invited to put up an exhibit at Edinburgh or London, that same nurseryman begins to cry out. My good friends in the trade tell me that foreign countries put so many difficulties in the way of English exhibitors that the latter must retaliate to secure reciprocity. Surely, however, this is the task of the admirably organised H. T. A., and is not the concern of the R.H.S., who should aim at getting all new, rare, or noteworthy plants at their meetings, irrespective of origin. There are a few questions I would like to put to the trade. Why is it patriotic to buy from abroad, via a middleman, and unpatriotic to buy direct? Is not the stock on which a Rose is budded more important than the country in which it is grown? I remember seeing an old nurseryman in a southern suburb of London chopping up clumps of Phloxes—received from Holland and for which he had paid 30s. a hundred—into five and six plants to be retailed at 8d. each! However, all is well in the best possible of worlds if you cultivate your garden and, as they say where vegetables are shown in competition, pick out the cork from the Cauliflowers! *William Lawrence.*

FOREIGN CORRESPONDENCE.

SURPRISING VITALITY OF A HYACINTH BULB.

A year ago, I placed some Hyacinth bulbs in water-glasses to bring them on during the winter months, between our German double windows, which are very appropriate for the purpose. One of the bulbs remained behindhand in forming roots for about four weeks, and on examination it was found that about one-third of the bottom was decayed. The decayed portion was scraped out and painted with tincture of iodine. The bulb now, as if it had felt itself to be cured, put forth two roots, but no more, and in course of time flowered satisfactorily, if a trifle below standard. What makes the case so surprising is that this bulb could accomplish with only two roots, that for which luckier bulbs think thirty, forty or even more roots necessary. *Wilhelm Sturz, Berlin.*

VEGETABLE GARDEN.

CAULIFLOWERS.

Those who kept to the old and commendable practice of sowing a good batch of an approved variety of Cauliflower in October last, will have reason to be pleased, for this vegetable is, I consider, one of the easiest to keep through the winter, and it can be forced in batches to suit the demand. I prefer to sow the seeds at the beginning of October and again at the end of the same month, as there is always the danger of quick growth in mild weather at that time of year. The seedlings should be pricked off into seed-boxes or frames, and by about the middle or end of November the plants should be ready to pot into two-and-a-half inch pots, when they should be placed in a cold frame, taking care they have plenty of air. Later, the pots may be placed on the shelves in fruit houses that are "resting." Early in the New Year hot-beds should be prepared for them, and covered with about nine inches of soil, which should not contain too much manure, in which to plant them.

In my estimation there is no vegetable easier to force than the Cauliflower, and by having relays of plants in pots it is very easy to maintain a supply from the beginning of April until a crop can be had outside; these latter also should be secured from the same sowing and grown on in pots. I am quite positive this method is much easier and better than sowing in spring. Spring-sown plants, I have found, turn in immaturely and form small kurds which spread so soon as a few warm days occur.

As to varieties, most gardeners have their own ideas about them; I myself am very much in favour of Sutton's Early Snowball and Dwarf Erfurt. *James Page.*

SOCIETIES.

ROYAL HORTICULTURAL.

April 9 and 10.—The show held in connection with the meeting on these dates was arranged at short notice to take the place of the postponed London Daffodil Show. In the circumstances a small show might well have been anticipated, but the reverse proved to be the case, and the new Horticultural Hall was well filled with a good variety of floral subjects. While Orchids were not quite so numerous as on recent occasions, there were several good groups in which the valuable Cymbidiums again predominated, while Cattleyas, Brasso-Cattleyas, Dendrobiums and Odontoglossums of splendid quality were also included. The Orchid Committee recommended two First Class Certificates and four Awards of Merit to novelties. Flowering shrubs, including very good Roses and Clematises; alpines and Schizanthuses, were the chief general floral subjects. The Floral Committee recommended two Awards of Merit to novelties. There were several excellent groups of Daffodils and a large number of seedlings before the Committee, which recommended two Awards of Merit. There was no business of moment transacted by the Fruit and Vegetable Committee.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Col. Stephenson Clarke, Mr. Lionel de Rothschild, Mr. Fred J. Hanbury, Mr. H. G. Alexander, Mr. J. E. Shill, Mr. Charles H. Curtis, Mr. A. McBean, Mr. S. H. Low, Mr. J. Cowan, Mr. Fred K. Sander, Mr. E. R. Ashton, Mr. Richard G. Thwaites and Mr. Robert Paterson.

First Class Certificates.

Miltonia Lucia var. Molly Paterson.—This was exhibited a fortnight ago, when the flowers were as described on p. 252. On this occasion, however, the colour had developed extraordinarily, with the result that a F.C.C. was awarded. The sepals are light rose, with lighter mottlings and red-purple veins at the base. The petals are crimson with rose apices, and the wide lip is pale rose with rose-red flushing below the golden-brown mask. Shown by Robert Paterson Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, Sussex.

Brasso-Cattleya Springtide var. The Node (Cattleya Mossiae × B.-C. Maroniae).—A gorgeous flower of very large size. The sepals and petals are light, bright mauve-purple and the broad, rounded lip has a lovely fringe of similar colour surrounding a large old-gold, richly-veined central area, with purple shading at the base. Shown by Mrs. Carl Holmes (gr. Mr. T. Penton), The Node, Welwyn.

Awards of Merit.

Odontioda Cardinal Mercier (parentage unknown).—A graceful hybrid with flowers of good size and shape; sepals and petals deep rose, flushed with crimson; lip light, bright rose, with deeper rose and some deep red markings. Shown by Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Odontioda Bluebell (parentage unknown).—A beautiful Orchid, with finely-formed flowers set closely on a stout spike. The colour is bright rose-purple, violet-tinted, flushed with crimson-purple, and with a few paler markings. The disk is golden-yellow and the bases of the petals and upper sepal are white. Shown by Gus Mayer, Esq. (gr. Mr. R. Cottam), Wistler's Wood, Woldingham.

Ansellia congoensis, Witley var.—A very large plant was shown, and one tall stem carried a branching spike on which only a few flowers were expanded. These were dark, red-brown barred with yellow, and with a yellow tip to the brown-veined lip. Shown by J. J. Joicey, Esq., The Hill, Witley.

Sophro-Laelio-Cattleya Gertrude Geidels (S.-L.-C. Flamingo × S.-L.-C. His Majesty).—A very large hybrid for this section. The sepals and petals are purple and the lip is rich crimson-purple, with a pale yellow throat. Shown by Messrs. Charlesworth and Co.

Cultural Certificates.

To J. J. Joicey, Esq. (gr. Mr. J. Mackay), for Megaclinium Bufo, with an unusually fine spike of this quaint species.

To Mrs. Carl Holmes (gr. Mr. T. Penton), The Node, Welwyn, for Odontoglossum Maharajah.

Groups.

The Orchid growers were not in quite such strong force on this occasion, nevertheless, they made a good show along the north side of the hall.

Messrs. Sanders exhibited Cymbidiums in good style, displaying fine spikes of C. Pauwelsii, C. Bullfinch, C. Erica Sander in variety, C. Primrose Queen, C. Elfin, etc. Dendrobium Wardianum and D. nobile added colour to the group, while Galeandra Devoniana, Masdevallia Lowii, Lycaste macrobulbon, Coelogyne Lawrenceanum, Vanda suavis var. Albania, and Cattleya Suzanne Hye de Crom were other good things.

Messrs. Charlesworth and Co. had a smaller display than usual, consisting of fine spikes of Odontoglossum crispum in variety, O. Clydonia, O. Isabel Sander, O. Decius, O. Alvara, and other splendid subjects. In Mr. J. Evan's small group, the chief subjects were Cymbidium Ceres, Miltonia Bleuana, and Bifrenaria Harrisoniae.

Messrs. H. G. Alexander, Ltd., staged a very bright and attractive exhibit in which Laelio-Cattleya Blinor, Westonbirt variety, L.-C. Orange Beauty and L.-C. Orange Gem provided splendid colour. Cymbidium Ladybird, Brasso-Laelio-Cattleya Freda, B.-L.-C. Caligula var. excelsa, Brasso-Cattleya speciosa, B.-C. The Globe var. magnifica, and Cattleya Egret, Westonbirt var., were also included.

Laelio-Cattleya G. S. Ball figured boldly in the group from Messrs. Cowan and Co. Cymbidiums were also shown in excellent variety, in addition to Dendrobium Thwaitesiae, Veitch's var., Masdevallia Chimaera var. stupenda, Odontioda Vuylstekeae and the dark-hued O. Laura.

Messrs. Stuart Low and Co. had a bright group wherein Dendrobium thyrsiflorum, D. Farmeri, D. Thwaitesiae, D. Pierardii and D. Royal Princess were particularly good. With these were associated Cattleya Dusseldorffii, Brassavola tuberculata, Zygopetalum crinitum, Angraecum sesquipedale and several Odontiodas.

Dendrobium plumptonense var. Model was grandly shown by Baron Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Floral Committee.

Present: *Section A.*—Mr. Henry B. May (in the chair), Mr. Arthur Turner, Mr. B. R. Long, Mr. A. E. Vasey, Mr. C. F. Langdon, Mr. D. Allan, Mr. Hugh Dickson, Rev. Rollo Meyer, Mr. M. C. Allwood, Mr. D. Ingamells, Mr. William Howe, Mr. J. M. Bridgeford, Mr. D. B. Crane, Mr. J. B. Riding, Mrs. Helen Lindsay Smith, Mr. Charles E. Pearson, Mrs. Ethel M. Wightman, Mr. R. Findlay and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. E. A. Bowles, Mr. G. Reuthe, Mr. George Harrow, Mr. L. R. Russell, Mr. W. B. Cranfield, Mr. James Comber, Mr. Eric Marston-Jones, Mr. Amos Perry, Mr. Clarence Elliott, Mr. T. Hay, Lady Beatrix Stanley, Mr. E. H. Wilding, Mr. A. Bedford, Mr. T. W. Taylor, Mr. F. G. Preston, Mr. G. Yeld, Mr. R. C. Notcutt, Sir William Lawrence, Bart., Mr. Gerald W. E. Loder and Mr. N. K. Gould, Secretary.

Awards of Merit.

Marica gracilis.—This Brazilian plant is closely related to the Iris, but the flowers are much more short-lived. It was introduced in 1830, and is figured in *Bot. Mag.*, tab. 3,713. A sturdy, well-grown little plant was shown. The outer segments of the flowers, set at right angles, are broadly ovate and white, except at the base, where the colouring is a golden-brown. The inner segments are curiously curved inwards, and are coloured bright blue, with prominent white lines. Shown by Sir William Lawrence, Bart., Burford, Dorking.

Viburnum Burkwoodii.—The parentage is given as Viburnum utile and V. Carlesii. In general habit this hybrid is much more like the former than the latter species. It is an erect-growing, robust, sub-evergreen. The leaves are opposite, ovate-lanceolate, stout, lightly serrated, shining green above and grey below. The panicles of white flowers which terminate the laterals are much like those of a good variety of Viburnum Tinus, and have a pleasing fragrance. The buds are pinkish. Shown by Messrs. Burkwood and Shipwith.

Groups.

At the far end of the hall, Messrs. Blackmore and Langdon set up an admirable group of Schizanthus Wisetonensis hybrids. The plants were shapely and bore large flowers of very pleasing colours. Messrs. Stuart Low and Co. had a group of tall bushes of Mimosas (Acacias) and Camellias, with good Hippeastrums, Anthuriums and Gerberas.

Roses were particularly well shown by several growers. Mr. Elisha J. Hicks included good vases of Clovelly, Ophelia, Mrs. G. Norwood, Madame Butterfly and Mrs. Elisha J. Hicks in his collection. The outstanding varieties shown by Mr. George Prince were Austrian Yellow, Austrian Copper, Orange Reflection and La Reine Elizabeth, in delightful sprays, and vases of Mabel Morse, Richmond and Lady Hillingdon. Messrs. F. Cant and Co. included vases of two new H.T. varieties, Dorothy Hodgson, pink, and Mrs. Hilton Brooks, salmon-blush.

Groups of specimen Polyantha Roses in pots were arranged by Messrs. W. Cutbush and Son, and Mr. J. H. Pemberton. The former displayed much better finish in the arrangement. The chief varieties were Locarno, Sunshine, Golden Salmon, Kersbergen and Ellen Poulsen. Mr. G. H. Dalrymple again set up a large collection of his admirable coloured Freesias. In addition to several vases of interesting seedlings, he showed Treasure, Mrs. R. F. Felton, Mendota, Old Rose and Yellow Hammer. Mr. Baldwin Pinney staged sweet Violets and Primulas.

The several collections of Carnations included many admirable blooms. Messrs. C. Engelmann, Ltd., had splendid vases of Laddie, Red Laddie, Master M. Stoop and Mrs. A. J. Cobb. In their exhibit, Messrs. Stuart Low and Co. showed White Pearl, Melchet Beauty, Thomas Ives and Topsy. Messrs. Allwood Bros. had an imposing group of the most popular varieties and many bowls of the pretty little Dianthus Allwoodii varieties.

Most of the exhibitors of alpines displayed their plants in small rock gardens of sandstone or weathered Cumberland stone. Messrs. Tucker planted good patches of Saxifraga arco-valleyi, S. dalmatica, S. Sundermanni, various Drabas, Primulas and other alpines. Messrs. M. Prichard and Sons had bright patches of Anemone fulgens var. polypetala, with Saxifrages, Primula dentata var. superba, P. altaica var. grandiflora and double-flowered Primroses. Mr. George E. P. Wood planted Violas, Primulas and Arabis, and Messrs. Hollambys had Primulas and Gentians.

In a boldly arranged rock garden, Mr. Gavin Jones displayed Draba Dedeana, Saxifraga Petraschii, S. Godseffiana, Primula pubescens var. alba and other seasonable alpines. Mr. Stephen Sims set out small Conifers, Ericas and Muscari; Ericas, Saxifrages, Primulas and dwarf Irises were the chief subjects shown by Messrs. Maxwell and Beale. A number of good alpines in pots and pans, shown by Mr. Clarence Elliott included Shortia uniflora var. grandiflora, Saxifraga Griesbachii, Wisley variety, S. Myra, S. scardica and some particularly good specimens of the compact form of the upright Irish Juniper. Bevan Rogers, Esq., Henley-on-Thames, had a praiseworthy collection of alpines in pots, among which were various Saxifrages, Primulas, Androsaces and Eritrichium. Mrs. Milford, Chedworth, Gloucestershire, showed alpines set in moss.

C. Scrase Dickens, Esq., Coolhurst, Horsham, staged an interesting collection of the spring-flowering Hellebores. Messrs. D. Stewart and Son had a bright exhibit which included pink-flowered double Cherries, Dielytra (Dicentra) spectabilis, Daphne Cneorum and many other spring subjects. Messrs. W. Wood and Son staged Magnolia stellata and other shrubs with Violas and alpines. Good Rhododendrons, Brooms, Azaleas, Primulas and Primroses were displayed by Messrs. Bakers. Next to their Schizanthuses, Messrs. Blackmore and Langdon set out very good blue Primroses and, near by, Mr. John Hall had sturdy pot plants of Primula denticulata var. Hallii. Dwarf shrubs were shown by Messrs. Patricks. Messrs. Pulham and Son exhibited a sandstone rockery, and the Misses Hopkins had a small rock garden exhibit.

Massed bushes of Forsythia spectabilis in the exhibit of Messrs. Barr and Sons were very effective. They also showed good varieties of Cydonia (Pyrus) japonica, Primula rosea, the old-fashioned Primrose Jack-in-the-Green, double-flowered Primroses, Viola Huntercombe Purple, Arabis Taplow Rose and Narcissus Bulbocodium. Messrs. L. R. Russell, Ltd., had an attractive grouping of Wistarias, Clematises, Azaleas and Boronia megastigma.

The association of various flowering Cherries and Forsythia spectabilis formed a very pleasing background to the exhibit of Messrs. Waterer, Sons and Crisp, who also displayed Aubrietias, Primulas, Daphne Blagayana, Tulipa praestans, van Tubergen's variety, and a good selection of Erythroniums. Messrs. W. H. Rogers and Son staged Azalea Apple Blossom, Skimmias, Morisia, Iris azurea and Anemone fulgens.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mr. G. W. Leak, Mr. G. Monro, Mr. W. B. Cranfield, Mr. A. White, Mr. W. Poupart, Mr. C. W. Needham, Mr. F. A. Secrett, Rev. Rollo Meyer, Mr. C. H. Curtis, Mr. Reginald Cory, Mr. H. Smith, Mr. F. Barchard, Mr. J. L. Richardson, Sir Daniel Hall, Miss E. Willmott, Mr. G. Churcher, Mr. W. Copeland, Mr. J. D. Pearson and Mr. A. Simmonds, Secretary.

Awards of Merit.

Narcissus Fanny Currey.—An exquisite variety of the Leedsii section, of very delicate colouring. The broad perianth segments, slightly ridged and waved, are of a delicate creamy-whiteness, while the frilled cup is rich cream, flushed with apricot on the margin. Shown by Mr. J. L. Richardson, Prospect House, Waterford.

Narcissus Golden Ingot.—A large-flowered Incomparabilis Narcissus, suggestive of a Trumpet Daffodil. The bloom is of fine substance, with broad, oval and flattened perianth segments of rich, bright primrose-yellow; the large cup, nearly one-and-a-half-inch long, trumpet-shaped and frilled at the mouth, is rich golden-yellow. The handsome blooms are held erect on stout stems, while the foliage is very substantial. Also shown by Mr. J. L. Richardson.

Quite a number of seedling Narcissi were exhibited before this Committee, the only variety other than the above two to receive recognition being Advance Guard, shown by Messrs. R. H. Bath, Ltd. as being suitable for market and garden purposes, and this was recommended for trial at Wisley. It is a Trumpet Daffodil, with a large, deep golden trumpet which is crinkled and reflexed at the margin, while the waved perianth segments are of paler colouring.

Groups.

As forerunners to the Daffodil Show next week, there were several magnificent banks of Narcissi displayed at this meeting; that set up by Mr. J. L. Richardson being of exceptional merit, portraying a high standard of skill both in cultivation—every bloom was of first-class quality—and arrangement. Trumpet Daffodils, in many forms and shades, were the dominant feature, but were not so much in evidence as to detract from the brighter beauty of the numerous Incomparabilis, Poeticus, Poetaz and other sorts, all in great variety. Among golden-trumpeted varieties we noted Golden Flag, Master Robert, Luxor, Nimrod, Carlton, Music Hall and Solaria; Marquis of Headfort, Beersheba (magnificent), Moira O'Neill, Tenedos, White Nile, Helen O'Hara, Suda and White Emperor were outstanding pale-coloured sorts, and there were several magnificent seedlings. The finest of the Incomparabilis varieties included Orange Glow, Koko, Damson, Mitylene, Fortune, Silver Plane, Brightling, White Sentinel and Therapia. Scarlet Gem was an attractive Poetaz, while there were also many beautiful Poeticus varieties. A really grand exhibit, possibly the finest in the hall.

Messrs. Barr and Sons staged an attractive group, comprising many varieties of each section. In the centre was an imposing pillar of Sunrise, while among the other varieties which commanded attention, mention may be made of Nero, Polemon, Glory of Haarlem, and Gold Sand, all Trumpet sorts; Lucille, Hera, Fiery Monarch, John Evelyn, and several double varieties, such as Glowing Phoenix, Carnation, Milk and Honey, Romagna and Lune de Noel. A small collection of Narcissi was displayed by Messrs. D. Stewart and Son, in which we noted good examples of the double-flowered Irene Copeland, also Spring Glory, King Alfred and several miniature sorts.

At the far end of the hall, Mr. F. A. Secrett had a grand collection, admirably arranged, and consisting chiefly of Poeticus varieties. There were large pillars of Wide Wing and Winnie Weedon, other splendid sorts in this section being Heron, Dinton Red, and the distinct and dainty Red Rim. A special feature was made of Everlasting, an Incomparabilis of good market quality, while there were also several striking Trumpet varieties, including Alfred Hartley, rich gold, and the beautiful, cream-coloured Kingsley Fairbridge.

Mr. Herbert G. Longford had an arrangement of Narcissi, consisting of pillars of such varieties as Croesus, Emperor, White Lady, Horace, King Alfred and Bernardino, and these acted as a background to Polyanthuses and Primroses in many shades.

Another really magnificent group of Narcissi was staged by Mr. R. F. Calvert, who made special features, in the form of large pillars, of Firetail, Liscarton and Chit Chat, together with Croesus, of grand quality, White Emperor and Medusa. There were numerous other first-class sorts in this charmingly arranged exhibit, not the least attractive being Yukon, Tenedos, Water Lily, Bradwardine, Fortune's Gem, White Sentinel, Amir, Clwyd, Fortune's Glory and Coverack Lad.

A small collection of Tulips was staged by Messrs. G. W. Miller; it contained numerous double sorts, also good blooms of Yorkshire Cheer, Prince of Austria and General de Wett.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. W. H. Divers, Mr. A. W. Metcalfe, Mr. W. Poupart, Mr. W. F. Giles, Mr. J. Wilson, Mr. A. Bullock, Mr. H. Markham, Mr. C. G. A. Nix, Mr. G. F. Tinley and Mr. A. N. Rawes, Secretary.

This Committee had no business of importance to conduct and there were no exhibits of fruits or vegetables in the hall.

MORAY AND NAIRN FORESTERS'.

The Annual General Meeting of this Society was held in Forres, Mr. E. S. Grant in the chair. In his opening address, the Chairman specially thanked those proprietors who had kindly granted facilities to the members for visiting their estates, and also the lecturers for the very instructive papers read before the members during the past winter. The reports of the Secretary, Treasurer and Librarian were submitted and considered satisfactory. The following were elected office-bearers for 1929-30:—President, Mr. F. Machray, Dunphail; Vice-Presidents, Mr. C. Bain, Mr. J. D. Robbie and Mr. A. Warren; Secretary, Mr. C. Asher; Treasurer, Mr. A. Ross; Librarian, Mr. J. Robbie; Auditors, Messrs. J. Clark and M. Feaks; Joint Journal Editors, Messrs. J. Clark and E. S. Grant. Six new names were added to the Committee. Provisional arrangements were made for visiting the following estates during the ensuing summer: Monaughty, Lethen, Sanquhar, Gordon Castle, Logie and Relugas.

PAISLEY FLORISTS'.

The annual Spring Show of this Society, which was instituted many years ago was held on March 29 and 30. Hitherto it was a one-day event, and as the exhibits were crowded into the limited space of one hall, an extension was made this year by staging the Tulips and flowering pot plants in an adjoining hall of smaller dimensions. The schedule contained fifty classes, but competition was not particularly keen owing to the influence of the hot weather on Tulips and Daffodils, some of which were too fully developed to justify special recognition. Hyacinths were a strong section, both as regards numbers and quality, and as an instance of the high standard of culture, it may be mentioned that in the class for three Hyacinths in a pot, Alex. Robertson, Esq. (gr. Mr. Duncan Graham), Bulgone, was first with three flower spikes of Jacques, each measuring eleven inches in length. The Special Prize for the best pot of Hyacinths in the show was awarded to Mr. E. G. Ross, who succeeded in producing twenty-three well-grown spikes of Grand Maitre.

Mr. Graham was the most successful competitor, with a record of twenty first prizes and the special prize for the best plant in the show (Primula obconica). Other prize-winners were Messrs. Hector Fraser, J. Bowie, J. Houston, E. G. Ross, T. Harvey, D. W. Keir and James Thomson. Special prizes were awarded to Mr. Hector Fraser, for the best Narcissus, variety Whitewell; Mr. John Bowie, for the best Tulip, variety Prince of Austria; and Mr. E. G. Ross, for the best Hyacinth, variety Grand Maitre.

The Parks Department of the Corporation was represented by an extensive group on the platform, in which Rhododendron Pink Pearl was used as a background to Hyacinths, Daffodils, Tulips, Deutzia gracilis and Cinerarias.

An interesting collection of Narcissi embracing thirty varieties was staged by Sir John Reid (gr. Mr. John Davidson), Ardencraig, Rothesay. Included in the exhibit was an improved form of Sir Watkin. The flowers were more solid, the perianth was of better formation, and the colour of the latter was a little lighter than that of the type. Other outstanding varieties in this group were Sir Francis Drake, Gloria Mundi, Homespun, Whitewell, Spring Glory, White Queen and Lord Kitchener.

GENERAL BULB GROWERS OF HAARLEM.

The different floral committees of this Society have awarded "Forcing Certificates" to the following Daffodils and Tulips:—

Early Forcing Certificates.

Narcissus Early Perfection (*Poetaz*).—Well-closed perianth, nearly white; cup clear yellow and frilled. Shown by Messrs. R. A. van der Schoot, at Hillegom, January 21.

N. February Gold (*cyclamineus hybrid*).—Perianth sulphur-yellow and recurved; small, orange-yellow trumpet; small flowers. Shown by Messrs. de Graaff Bros., and S. A. van Konijnenburg and Co., at Noordwijk, December, 24, 1928.

Tulip Attraction (*Single, early*).—Deep orange with scarlet shading. Shown by Messrs. N. and J. Roozen Bros., at Heemstede, December 24, 1928.

T. Captain of the Violets (*Single, early*).—Vivid violet, large, oblong-shaped flower. Shown by Mr. Th. van der Vlugt, at Lisse, December 24, 1928.

T. J. A. Geysendorffer (*Single, early*).—Orange-brown. Shown by Mr. L. Schoorl, at Lisse, December 24, 1928.

Forcing Certificates.

Narcissus Lord Wellington (*Yellow Trumpet*).—Very big, golden-yellow flower, large, with flat perianth and long, wide-opened trumpet. Shown by Messrs. A. Frylink and Sons, at Sassenheim, February 4.

Tulip Fascination (*Single, early*).—Soft pink-rose. Shown by Messrs. W. J. Eldering and Son, at Overveen, December 31, 1928.

ANSWERS TO CORRESPONDENTS.

Begonia and Chickweed Foliage Unhealthy.—*C. E. C.* There was no fungus present on the Begonia and Chickweed foliage. The trouble appears to be due to some cultural error. Rapid changes in temperature or unsuitable soil conditions are liable to give rise to this trouble.

Celery Disease.—*J. C.* It is possible to obtain dry Bordeaux mixture, to which water is added when required for use. Either "Cupryl" (Messrs. W. J. Craven and Co., 48-50, Port Street, Evesham), or "Vermorite" (Messrs. Cooper, Pegler and Co., Christopher Street, Finsbury Square, London), may be used for spraying Celery plants in the seedling stage. The wash should be applied in a mist-like form so that the fungicide is evenly distributed over the foliage. Spraying must be continued at intervals after the plants are placed in their permanent quarters.

Colletia teniculata.—*G. P.* There is no evidence that this species has ever been introduced to cultivation. Of thirty-nine species that have been described only four are to be found in gardening dictionaries. They are not particularly hardy in Britain, and have to be planted in sunny, sheltered situations, and that militates against their introduction. They are difficult to describe and some of them are not constant to form. C. teniculata means "rather slender," and you will note that the spines are more slender, more straight and shorter than those of C. spinosa. The flowers of the latter are described as yellowish-white or greenish-white by different authors. The flowers of other species are described as cream, pale yellow and yellow. No doubt the flowers of C. teniculata are some of those shades, but in the dried, herbarium state they are brown, like all the rest. Any private collector might have brought home fruits, without recording the fact, or might have considered it to be C. spinosa.

Control of Club Root with Mercuric Chloride.—*J. C.* Mercuric chloride (corrosive sublimate) has been found to give good control of club root of Brassicas. The method employed is to sterilise the seed bed by watering it with a solution of one ounce of mercuric chloride in six gallons of water (the quantities may be reduced proportionately if less is required), and ten days after germination the seedlings should be watered with a solution of one ounce in ten gallons of water, the watering being repeated seven days later, and again a few days previous to planting time. Before being planted, the seedlings should be dipped for one minute in mercuric chloride solution of one ounce in ten gallons of water (proportionately less if so desired). Among precautions to be observed are:—(1) use only finely-powdered material; (2) do not confuse mercuric chloride or corrosive sublimate with insoluble calomel or "mild mercuric chloride," as it is sometimes called; it is best to ask for corrosive sublimate when purchasing of a chemist; (3) apply enough solution to moisten the soil about the base of the seedlings thoroughly; (4) do not water the seedlings at the germinating stage, but allow ten days to elapse; (5) a weaker solution (one ounce to fifteen gallons of water) should be used on sandy soil, or in the case of uneven germination; and (6) as corrosive sublimate is a deadly poison it should be handled with extreme care. The experiments in controlling club root with mercuric chloride have been carried out over a number of years at the Staffordshire Farm Institute, where it has also been found to give effective control of root maggot, black leg and black rot of Brassicas. The material is not expensive and can be obtained from most retail chemists at a cost of about 1s. 4d. per ounce.

Difficulties with Hot-water Pipes.—*R. E. G. B.* (1) It would seem to us that something is wrong with the escape of smoke and heated air from the boiler to the chimney. A horizontal tubular boiler should be fitted up horizontally. The furnace door in most, if not all, boilers should determine the fixing of the boiler before it is built in with bricks. Erratic methods for the uniform passage of smoke from the furnace to the chimney are to be met with in some establishments, and they are usually very unsatisfactory in heating and also to the stoker, when there are dips and bends in the passage for smoke. If this is straight and always on the rise, the rest is easy, and a proper use of the damper, and the furnace and ash-pit doors, will regulate the fire to a nicety. We think the re-erection of the boiler desirable. (2) One of your statements we do not understand, namely, "the pipes in the second and third (house) are laid much more even than the first three." If you mean "than the last three," that might explain matters. The flow pipe should rise steadily from the boiler to the far end of the sixth house, where an air tap should be situated. Hot water always rises, and it should pass along the flow pipe to the farthest end, if the piping is continuous. It is just possible that the supports of the pipes in the last three houses, farthest from the boiler, were right at first, but may have become sunken in the soil of the floor, and no longer keep the pipes rising. It would be advisable to see to this, and have them raised, if necessary. We do not see the necessity for a stop valve on the return pipe, close to the boiler, because that would stop the circulation.

Insects in Cucumber House.—*H. M. B.* The small insects found in the Cucumber range are a species of Pseudococcus, one of the grass-feeding, soil coccids or root mealy-bugs. There is little chance of the insects attacking the roots of Cucumbers, but they may be eradicated from the borders by injecting carbon disulphide into the soil. Holes, about six inches deep, are made, and the liquid poured into them at the rate of one ounce to each square yard. After pouring in the liquid, cover the hole with a stone or piece of turf to conserve the fumes. The material is highly inflammable, and no naked light should be brought near it.

Names of Plants.—*P. D. F.* Ipomaea tuberosa, a native of central America.—*M. P.* 1, Erica carnea var.; 2, Saxifraga, probably apiculata; 3, not recognised. The material sent was insufficient for accurate identification.

Soil in poor Condition.—*R. R.*—There appears to be a large excess of burnt material in the soil, and no doubt if it was mixed with about one-third leaf-mould, with the addition of sand, it would be suitable.

Tomatos and Foot-rot Disease.—*S. E.* The Tomato plants are infected with the foot-rot fungus, Phytophthora cryptogea. Infected soil should be sterilised by steaming or with a two per cent. solution of formaldehyde. The seedlings should be watered with Cheshunt Compound, which will destroy the disease organisms in the soil, but will not benefit plants already infected, as the fungus is within the tissues of the plant where the liquid cannot reach it. Remove and burn infected plants, and water the remainder with Cheshunt Compound.

Tulips Diseased.—*J. W.* The Tulip bulbs are severely affected by the fungus Botrytis tulipae and by millipedes, Polydesmus complanatus. All infected bulbs should be removed and burnt, while the soil surrounding them should be taken away and buried deeply. Care should be taken to see that all bulbs are removed, otherwise sclerotia will form on the brown scales surrounding the nose of the bulbs, and on the remains of the foliage, and cause the ground to become infected. So soon as the bulbs are removed, the ground should be dressed with crude naphthalene at the rate of two to three ounces to the square yard in order to destroy the millipedes. More efficacious results will follow when the naphthalene is watered in, or applied prior to rain.

Daffodils in a Woodland.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 48·6°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, April 17. 10 a.m. Bar. 30·4 Temp. 54°. Weather, Fine.

Primula kewensis. GRADUALLY, and as though reluctantly, plant hybrids begin to reveal to the patient geneticist some of the secrets of their birth and behaviour. Such, at all events, appears to be the case with Primula kewensis, that hybrid of well-known and peculiar history which chance brought forth twenty-nine years ago at Kew among a batch of Primula floribunda seedlings. The solitary come-by-chance was suspected to be a hybrid between the Afghan species P. floribunda and the Arabian and Abyssinian P. verticillata. Pollenations of P. floribunda by P. verticillata made by Mr. J. Coutts at Kew proved the truth of the suspicion, but, strange to relate, subsequent attempts to reproduce the hybrid by the same cross proved unsuccessful. Cytological examination of the dividing nuclei of P. kewensis shows that this hybrid is what is known as "diploid," that is, it has twice the number of chromosomes (eighteen) contained in the corresponding cells of either of its parents. In this state, namely, with the double number of chromosomes, P. kewensis is infertile. Self-pollenation yields no seeds, nor does pollen of either parent species when used on the stigma of P. kewensis produce viable seeds. Pollen of the hybrid, on the other hand, used to fertilise P. floribunda, does induce seed formation, albeit that the plants so produced are mainly of P. floribunda type with some signs of hybrid influence. This might be explained by supposing that of the pollen grains produced by the hybrid some have more or less the nine P. floribunda chromosomes, and such pollen grains of the hybrid effect fertilisation, whereas other of the pollen grains of the hybrid containing chromosomes of P. verticillata origin are ineffectual and fail to fertilise the egg cells of P. floribunda. If one of the nine chromosomes of a pollen grain were of the P. verticillata type, and the other eight were of P. floribunda type, then the offspring would be P. floribunda with one or two characters of P. verticillata. Although, as has been stated, the diploid hybrid—that is, the original Kew plant with eighteen chromosomes—is infertile, it has happened on three occasions that seeds have appeared in hybrid (kewensis) plants, first in 1905, in the nursery of Messrs. James Veitch and Sons, and later, in 1926, at the John Innes Institution, when it was shown that the plant which so dramatically reversed the traditional habit of the hybrid was, unlike its infertile fellow-hybrids, not a diploid plant with eighteen chromosomes, but a tetraploid, that is, a plant with four times the number (thirty-six) of the chromosomes possessed by either parent. With this sudden doubling of the chromosomes P. kewensis became fertile. For the detailed explanation of why this should be so, the reader may be referred to the account of the investigations by W. C. F. Newton and Caroline Pellew,* on which this summary is based; it must suffice here to state that if the ordinary cells of the vegetative body contain each thirty-six chromosomes, the reproductive cells will contain eighteen. Of this number, nine may be supposed to be of P. floribunda origin and nine deriving from the other parent, P. verticillata. Hence, when male cell unites with the female, fertile issue is produced, because each of the chromosomes of the male finds a compatible chromosome in the female cell, and fuses with it, and so with each chromosome successfully paired the fecund union of male and female cell is assured.

Our Supplement Plate.—As Daffodils occupy the foremost position in our gardens at the present time, we have pleasure in presenting as a Supplement Plate to our present issue, an illustration depicting the fine effect obtained with Daffodils in Mr. Price's woodland garden at Knollwood Farm, Port Chester, New York, U.S.A. The scene presented is typical of many such in large English gardens at the present season, and emphasises the value of the Daffodil for naturalising purposes. Other views showing the effects obtained with Daffodils at Knollwood appeared in our issues of April 21 and June 2, 1928.

Appointment of Members of National Mark Fruit Trade Committee.—In view of the extension of the National Mark Scheme to Tomatos and Cucumbers, the Minister of Agriculture and Fisheries has approved the appointment of Mr. A. G. Linfield, Mr. John Poupart and Mr. E. G. Shoults, to be additional members to the National Mark Fruit Trade Committee, which is responsible for the consideration of applications to use such grade designation marks as may be prescribed by regulations made under the Agricultural Produce (Grading and Marking) Act, 1928, in connection with home-grown fruits.

The Foundling Hospital Site as a Park.—The rescue of the site of the former Foundling Hospital, in central London, from development at the hands of builders appears to be assured, at any rate for the immediate future, by a contract which is being prepared between the owners and Viscount Rothermere, the brother of the late Lord Northcliffe. This provides for the sale of the site to Lord Rothermere at the price of £525,000. A deposit of £50,000 is being paid by Lord Rothermere, together with interest on the remainder at five-and-a-half per cent. per annum until June 30, 1931. If by that time the purchase is not completed the site will revert to the vendors. Lord Rothermere will make a further contribution of £50,000 towards the purchase money, making £100,000, in addition to his liability for interest on the balance outstanding. The only condition he makes is that the entire site shall be used as a children's park, subject to a reservation that for one month in the year it shall be placed at the disposition of the British Boy Scouts Association for a camping ground.

Peter Barr Memorial Cup.—The handsome Peter Barr Memorial Cup, which perpetuates the memory of Peter Barr as a great pioneer in the popularisation of Daffodils, is awarded annually by the vote of members of the Royal Horticultural Society's Narcissus and Tulip Committee. The voting takes place on the occasion of the London Daffodil Show, and on Tuesday last, it was unanimously in favour of Mr. G. W. Leak, of Messrs. R. H. Bath, Ltd., Wisbech, a Vice-Chairman of the Committee, a member of the R.H.S. Council, and a raiser and extensive cultivator of Daffodils.

Rhododendron Association.—The second Annual General Meeting of the Rhododendron Association will be held in the Lecture Room of the Royal Horticultural Society's New Hall, Westminster, S.W.1, on Tuesday, April 30, 1929, at 4.30 p.m., when the Annual Report and Accounts for 1928 will be presented, and officers elected for the ensuing year. We notice, in connection with the Rhododendron Show on April 30, that, of the four new classes inaugurated, one is for six varieties of Rhododendron foliage, and another for "the best foliage Rhododendron plant."

Correct Name of the Larch.—In the *Quarterly Journal of Forestry* (April, 1929), Mr. T. A. Sprague, of the Herbarium, Royal Gardens, Kew, points out that the correct name of the Larch under International Rules is Larix decidua, Mill. In order to ascertain the correct name of a species, all its names should be placed in strict chronological order starting from 1753. In the case of the Larch, we have the following synonymy: Pinus Larix L. (1753), Larix decidua, Mill. (1768), Pinus laeta, Salisb. (1796), Abies Larix, Poir. (1804), Larix europaea, DC. (1805), Larix pyramidalis, Salisb. (1807), Larix communis, Link (1827), Larix vulgaris, Fisch. ex Spach (1842), Larix Larix, Karst. (1880-83). The Rules (Art. 48) provide that when a species is placed in another genus, it should take the earliest legitimate specific epithet, unless the resulting combination is barred by the rules themselves. The earliest specific epithet is Larix, 1753, but the resulting combination Larix Larix, Karst., is barred by Art. 55, 2°, because the specific epithet is identical with the generic name. The next name in chronological order is Larix decidua, Mill., and that is the correct name of the species. To anyone familiar with the International Rules, there can be (on the basis of the known facts) no doubt about the matter, and the name Larix decidua is accordingly accepted by all taxonomists who adhere strictly to the Rules.

Cornish Flower Growers' Visit to Lanarth.—Growers from the Penzance and Tamar Valley districts were entertained on Tuesday, April 2, by Mr. P. D. Williams, at Lanarth. The weather conditions were ideal, and the lawns and grounds looked beautiful under a blazing sun. Glimpses of brilliant colour could be caught in all directions, the fiery-red of Rhododendrons showing up in striking contrast against a background of tall Bamboos and white Magnolias. Drifts of the gold of the Narcissi, and the blue of Scillas formed living carpets of colour. Some forty growers attended to see the results of the work of Mr. P. D. Williams in the breeding of new varieties of Narcissi, and they were conducted to the beds of new seedlings by Mr. Williams, who personally acted as guide throughout the afternoon. The air of expectancy quickly changed to wonder, amazement, and in many cases even to envy. All present admired the wonderful display of some thousands of lovely new varieties. Some of the seedlings most admired included Niphetos, a pure white Leedsii, the shape and proportions of which are considered to be perfect. Seedling No 35 is a beautiful rich yellow of the Jonquil type. Great interest also centred around the grand varieties Fortune, Damson, Tunis and Nimrod, and the seedlings numbered 228, 886, 555, 713 and 938, the last being a beautiful Incomparabilis with a perfect yellow perianth and deep orange trumpet of very fine texture. Later, the growers were entertained to tea by Mrs. P. D. Williams, after which the Rev. A. T. Boscawen, of Ludgvan, proposed a vote of thanks to Mr. and Mrs. Williams, which was seconded by Mr. Rogers, of St. Dominic, and heartily endorsed by all present. Mr. Rogers said that only by such a visit to Lanarth and a personal inspection of the new varieties, could one fully appreciate the work of Mr. Williams, which called for untiring energy and great interest. Mr. Williams, in reply, stressed the importance of keeping bulb plantations free from rogues. He thought there were tremendous possibilities in the bulb industry, especially in the dry bulb trade. Growers in other parts of the country, and the forcers of Spalding and Wisbech, wanted Cornish bulbs as they were earlier than any others, but they wanted clean bulbs true to name, and these could not be produced without closer attention to rogueing. He also emphasised the importance of grading bulbs, separating the "mothers" from the "rounds" and the "rounds" from the "chips," and the growing on of "chips" to produce "rounds" for forcing. He congratulated the growers on their improved standard of marketing, and hoped that they would continue to enjoy the good markets ruling at present, for Cornish produce. A small party, including those from the Tamar valley, afterwards visited the gardens of Mrs. Whale, at Coverack, where more Narcissus seedlings were found growing luxuriantly. Other market flowers were being picked, these including Polyanthuses and Myosotis.

---

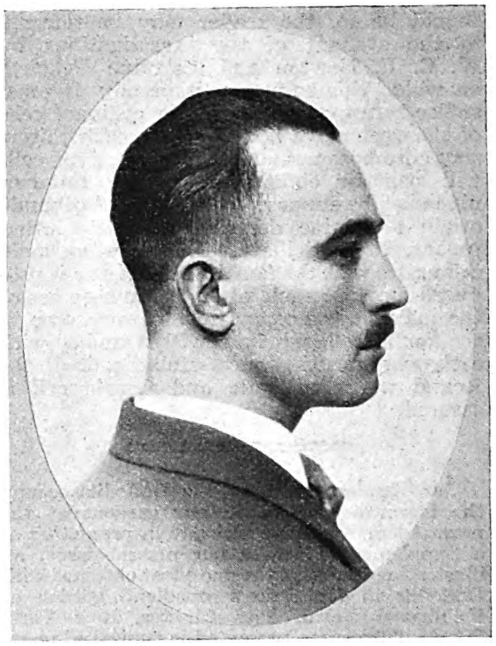
* "Primula kewensis and its Derivatives," by the late W. C. F. Newton, and Caroline Pellew, of the John Innes Horticultural Institution. *Journal of Genetics*, Vol. XX, No. 3, January 1929.

Rosa gigantea in flower at Cambridge Botanic Garden.— Rosa gigantea, so rarely seen in bloom, is now flowering in the Cambridge Botanic Garden. The specimen is in the extreme west end of the corridor and in a positon where it has the advantage of full sunshine. It has only one expanded flower, pale lemon-white in colour, and four-and-a-half inches in diameter, but there is every promise of more blooms, as indicated by nine golden-yellow buds. Mention is made in *The Gardeners' Chronicle* of 1910, Vol. XLVII, p. 370, of Rosa gigantea having borne two blooms at Kew, for the first time. Previous to this, the species was figured in these pages in 1889; flowers were shown on February 25, 1910, from the Duke of Northumberland's garden at Albany Park, Surrey; it flowered in the same gardens in 1903, when two blooms were produced, and again the following year, when the plant carried upwards of a dozen flowers. There are no records of this Rose having bloomed before in this country, excepting in the nurseries of Mr. Cant (see *Bot. Mag.*, t. 7,972). Sir George Watt first discovered the species in Manipur in 1882. Later it was found in the Shan Hills, Upper Burmah, and later still by Dr. Henry in south-western China.

Cider Inspection at Long Ashton.—On Thursday, May 2, at the Research Station, Long Ashton, Bristol, the ciders made during the season 1928-29 will be displayed, and the fruit plantations of the Station will be open to visitors from 11 a.m. to 4 p.m. The Ministry of Agriculture and Fisheries has arranged for a series of demonstrations of the most modern types of small tractors and other implements suitable for fruit-growers and market gardeners. These will be given at intervals during the day. It is anticipated that this feature of the programme will be of particular interest and practical value, and it is hoped that fruit-growers will make a special effort to attend.

Glasgow Flower Show.—The Glasgow and West of Scotland Horticultural Society, in conjunction with the Glasgow Corporation, will hold a great flower show in the Kelvin Hall, Glasgow, on September 3, 4 and 5. The schedule and the "Traders' Prospectus" have both been distributed. The former is enlarged, and now includes twenty-three classes for bee-keepers, while the prize-money is stated to be over £1,200, and there are numerous Challenge Cups, Trophies and Medals. The Glasgow Show is the largest and most important held in Scotland, and attracts visitors from all over Scotland and the north of England. The Kelvin Hall has been specially built by the City Corporation for the purpose of such displays, and is one of the most spacious and interesting buildings of its kind in the country. The Show Secretary is Mr. J. Carrick Weir, 115, St. Vincent Street, Glasgow, C.2.

Mr. L. E. Morgan, N.D. Hort.—The Parks Committee of the County Borough of Stockport, controlling some twenty parks and recreation grounds in the borough, recently appointed Mr. L. E. Morgan, N.D.Hort., as its Parks Superintendent. Mr. Morgan was throughout intended for the public branch of horticulture, and commenced his career in the Parks Department of the Borough of Crewe under his father, Mr. M. Morgan, the Superintendent. A period of five years was spent at Crewe, during which time he also received a clerical and surveying training, and attended Manchester University for botany classes; this was followed by a term at the R.H.S. Gardens, Wisley, under the late Mr. S. T. Wright. From Wisley he went to Mesopotamia on war service, and was transferred to the Civil Administration as Assistant to the Deputy Director of Agriculture for Iraq. At the close of the war he joined the landscape staff of Messrs. Dicksons, of Chester, as assistant, and here obtained further landscape experience in all branches of the work. In 1919, he received an appointment under Mr. W. W. Pettigrew, at Manchester, and up to the time of his present appointment had been Horticultural and General Assistant under Mr. Pettigrew. During this period, following the war, the Manchester Parks Department carried out works costing nearly £400,000, mainly for the relief of unemployment, and it was Mr. Morgan's duty to prepare the plans, estimates and detailed requirements, and to set out and supervise the work in general on the site. In addition, his duties included the laying out of recreation and ornamental areas, and street-tree planting for other Committees of the Corporation and various other authorities, including the very extensive work of the housing estates of the city. Mr. L. E. Morgan holds the National Diploma in Horticulture in public park gardening, and is a frequent lecturer on the subject. He is supposed to be the first to lecture on horticulture through the microphone; this was in January, 1922, from the Westinghouse Station. His activities on behalf of the staff of the Manchester Parks Department are known to our readers, as he inaugurated the Staff Society, the first of its kind. His efforts on behalf of the juniors of the Manchester Parks Department in arranging classes and other instructional facilities, including the series of authoritative lectures and the *Journal* of the Society, have been greatly appreciated by the whole staff, all of whom join in good wishes to Mr. Morgan on his new appointment.



MR. L. E. MORGAN, N. D. HORT.

British Science Guild.—Under the auspices of the British Science Guild, and in connection with developments of British Chemical Manufactures, a public meeting will be held at the Mansion House, London, on Wednesday, April 24, when Lord Melchett, F.R.S., President of the Guild, will preside, at 4.30 p.m. The speakers include Sir Frederick Keeble, C.B.E., F.R.S., who will deal with "Fertilisers from the Air," Mr. A. V. Shearer, who will discuss "Rayon (Artificial Silk)," and Mr. Francis H. Carr, who will discuss "Synthetic Drugs."

Olive-growing in Spain.—An interesting review of the Spanish Olive-growing industry appears in the *Monthly Bulletin of Agricultural Science and Practice*, Part I, and important facts are given relating to the development and present-day importance of Olive culture. Spain is stated to be the chief Olive-growing country, and the one in which the cultivation of this fruit is most highly developed. It produces about half the total production of the world, and the industry is still being developed. Olives are grown throughout the whole Peninsula, with the exception of the north-western district, the total area at present under Olives being 1,759,215 hectares; the average annual production of oil is 3,487,000 quintals, at a gross value of about 700 million pesetas. There are, approximately, 160 million Olive trees in Spain (an average of 91 trees per hectare of cultivated land); the highest proportion is reached in Cuenca, with an average of 207 trees per hectare, and the lowest in Orensa and Tarragona, with 46 and 56 trees per hectare, respectively. Seville is the centre of the Olive-preserving industry, about 140,000 quintals of Olives being bottled annually in this district for export; Cordova is next with 90,000 quintals. About thirty varieties of Olives are cultivated in Spain; the wild Olive, which grows in the mountains and fields and is called Acebuche, is seldom employed for oil extraction, but is frequently used for pig fattening. The most important commercial varieties are:—Picuda, late-fruiting and a heavy bearer; Cornezeula, which is most tolerant of low temperatures, produces a good quality oil, and is grown chiefly in the central districts; Verdial, a late variety, highly resistant to cold and drought, and yielding a high percentage of oil; Morcaleña, a fair cropper, whose fruits are grown more for consumption than for oil, which is of inferior quality; Arbequina, early maturing, and a heavy yielder of good quality oil; Bellotuda, rather late, and suitable for all soils; Lechin, a good cropper and resistant to cold, grown chiefly in Andalusia; Zorzaleña, the most important Olive of Seville, where it forms seventy per cent. of the Olive yards, cropping abundantly and regularly and yielding an excellent oil; Racimas, early, giving oil of medium quality, grown in Caceres but little elsewhere; Cordovi, not grown widely, but desirable as its fruits are suitable for consumption when green; Rapa Sayos, produces little, but very high quality oil, which is valued as a substitute for butter, while its fruits are also preserved; Manzanilla, grown for both oil production and preserving, and tolerant of cold, but not heat; and Cordal Sevillana, much prized for its fruits—the largest—which are preserved and exported in considerable quantities. The usual methods of propagating Olives in Spain are by cuttings, "garrotes," suckers, layers and root-cuttings, seeds and grafting. Prunings are frequently utilised as cuttings, but this method of increase is not employed generally; it is confined chiefly to the vale of the Betis. Propagation by "garrotes" is the method employed most extensively. Two or three Olive twigs are placed horizontally at the bottom of a hole and covered with soil (usually during February and March), and these produce plants rapidly and at low cost. The raising of Olives from seeds is limited, at present, to some very encouraging experiments at certain experimental stations under the Spanish Ministry of Agriculture. In Spain, the Olive is often grown in association with other commercial crops; with the Grape, Almond, or the Carob, in the east; the Hazel, in Catalonia; and with cereals or legumes in Castile and Andalusia. Pruning is the most important operation in connection with Olive culture, and is practised assiduously in Spain. Until the tree is fully developed, "formation" pruning—shortening all secondary and tertiary growths—is practised, and once the tree commences to bear it is thinned and pruned regularly after the harvest. During the summer, any basal or trunk growths which may appear are removed. Like cultivators of other fruits, the Olive-grower would appear to have many pests and diseases to contend with; it would seem that the Olive fly (Dacus oleae), is the most destructive pest, for we are informed that the total losses caused by it represent about five per cent. of the value of the average Olive yield.

Mr. Percy F. Bunyard.—At a recent meeting of the Council of the British Carnation Society, it was unanimously decided to elect Mr. Percy F. Bunyard an Honorary Life Member of the Society, and to present him with a Gold Medal, suitably engraved, in recognition of his valuable services as Hon. Secretary to the Society for the past ten years.

The "Ideal" Apple and Pear Grader.—Fruit growers and representatives of the Fruit and Vegetable Committee of the National Farmers' Union, to the number of about thirty, recently attended, by invitation, a preliminary demonstration of the "Ideal" Apple and Pear Grader, arranged by the Ministry of Agriculture. This grader is of a type used extensively in America, and differs in principle from the better-known Cutler Grader in that sizing is done by diameter, and not by weight. The possibilities of this machine for grading Pears was a matter of general comment. It is intended to give further working demonstrations of this machine in the provinces as opportunity offers.

Wolverhampton Floral Fête.—West Park is, as usual, to be the venue of this year's Floral Fête at Wolverhampton, which will take place on July 16, 17 and 18. The newly-issued Schedule of classes and prizes shows little variation from that of preceding years, except that prizes in general are of increased value, and an entirely new class has been provided for a group of Fuchsias, staged on a space twelve feet by four feet, for which the prizes are £5, £3, £2 and £1, respectively. A special feature this year will be the provision of twenty-eight classes for outdoor exhibits of garden tools and furniture, the prizes in these being medals or Awards of Merit. The usual handsome challenge trophies are offered for special displays and for the best non-competitive exhibits. The Wolverhampton Floral Fête of 1928 was visited by over 60,000 people.

Appointments for the Ensuing Week.—TUESDAY, APRIL 23: Royal Horticultural Society's Committees meet (two days); Cornwall Spring Flower Show (two days); National Bulb Society's Daffodil and Tulip Exhibition (three days). WEDNESDAY, APRIL 24: Newcastle and District Horticultural Society's meeting; Brentford and District Spring Show; Royal Dutch Society for Gardening and Botany's Rotterdam Spring Show (five days). SATURDAY, APRIL 27: Leeds Paxton Society's lecture.

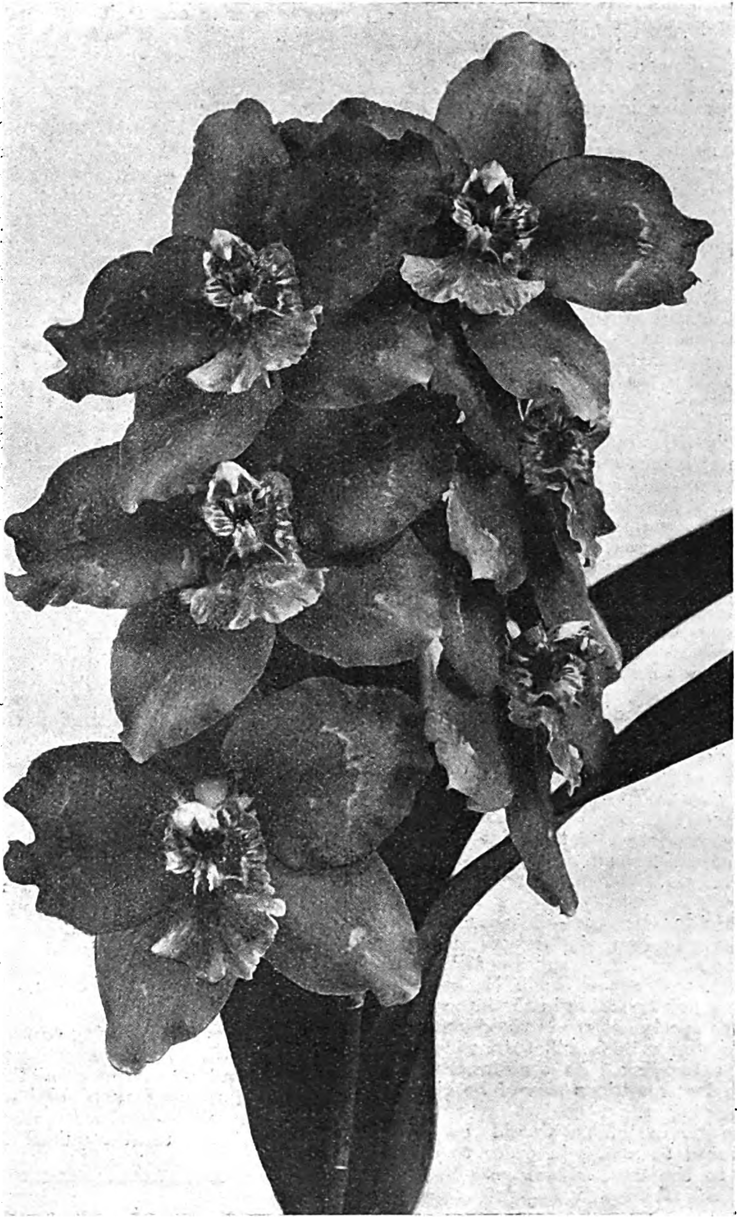


FIG. 147.—ODONTIODA BLUEBELL.

R.H.S. Award of Merit, April 9. Flowers rose-purple, violet-tinted and crimson-shaded.

Shown by Gus Mayer, Esq. (gr. Mr. R. Cottam), Wistler's Wood, Woldingham.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Effects of the late Winter.*—The temperature here, on January 3, 1854, fell 4° below zero, and on the grass 6° below zero, whilst in the valley in the neighbourhood it was 8° below zero. From our own grounds we have cut down above a hundred cart-loads of dead trees within the last month. Cedrus Deodara, every leaf fallen off and some boughs killed, but the plants are recovering rapidly; Cedar of Lebanon, slightly injured; Mount Atlas Cedar, injured; Acuba japonica, much injured, some plants killed to the ground; Viburnum Tinus almost all killed, the bark of the thick wood having been burst by the frost; Arbutus Unedo, all killed, some specimens were thirty years old, the bark forced off the trees by the frost; Pinus Cembra, not injured; P. excelsa, slightly injured; P. insignis, injured; P. Lambertiana, slightly injured; P. Laricio, slightly injured; P. Pinaster, not injured; P. Pinea, injured; Larix pendula, not injured; Abies canadensis, not injured; A. cephalonica, not injured; A. Menziesi, not injured; A. Morinda, not injured; A. Nordmaniana, not injured; A. Pindrow, not injured; A. Pinsapo, not injured; Araucaria imbricata, many killed; Quercus suber, much injured; Q. ilex (Evergreen Oak), many killed, some plants fifty years old dead; Erica mediterranea, much injured; Ilex aquifolium, many killed, all more or less injured, mostly the lower six feet of the trees are quite dead, making nearly all the trees standards; Cupressus funebris, much injured; C. Goveniana, ditto; C. horizontalis, ditto; C. thurifera, killed; C. torulosa, killed; Cryptomeria japonica, not injured; Yucca gloriosa, very much injured, all the branches killed, together with a portion of the stem; Buxus chinensis, killed; B. argentea, injured; Cerasus lusitanica, many killed; Laurus nobilis, killed; L. regalis, many killed; Roses, China and Tea-scented, many killed; Libocedrus chilensis, injured; Hedera Helix, injured; Ulex europaeus, many killed; U. e. flore pleno, ditto; Ligustrum vulgare, injured; Alexandrian Laurel, much injured; Phillyrea angustifolia, trees twenty years old, killed; P. media, ditto; Juniperus chinensis, not injured; J. communis, injured; J. excelsa, uninjured; J. recurva, ditto; J. Sabina, much injured; Taxodium sempervirens, scarcely injured; Tulip Tree, slightly injured; Rhododendrons, many killed, even the Pontic varieties injured; Garrya elliptica, nearly killed; G. laurifolia, killed; Yew (common) some injured; Walnut, ditto. Bees in many hives frozen to death, with nearly 20 lbs. of honey in them. I might have swollen this list, but the above will be sufficient to show that we have not, for fifty years at least, had such a severe cold. It is worthy of remark that in one place, near Nottingham (Watnal), the Bay Tree has not been injured. Probably no part of England has suffered to the extent that we have near here, especially between this place and the Earl of Harrington's and Newark. *E. J. Lowe, Highfield House Observatory, near Nottingham, April 10. Gard. Chron., April 22, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Cycnoches, Catasetums and Mormodes.—For cultural purposes these deciduous Orchids require similar treatment, although their habits of flowering are slightly different. Cycnoches develop their flowers from the axils of the leaves on the upper part of the newly-made pseudo-bulb, while species of the other genera usually produce their flowers from the bases of the pseudo-bulbs. Plants which have been resting in an airy position in the intermediate house since maturing their growths in the autumn, are now commencing to grow, and repotting may be done forthwith. Turn the plants out of their receptacles, remove all old compost, and cut away all decayed roots and useless pseudo-bulbs, after which place them in well-drained pots or pans in a compost of equal parts of Osmunda and A.1. fibres, one part Sphagnum-moss, and a little fibrous loam, adding crushed crocks or charcoal to keep it porous. Avoid over-potting, but make the soil firm; keep the bases of the pseudo-bulbs level with the pot rim and just in contact with the compost. Very little water is needed until the new roots are well established in the soil. These Orchids delight in moist surroundings and a light position in the warmest house, only lightly shaded from strong sunshine, in the early stages of growth. Care should be taken not to allow any moisture to collect in the young growths or decay will quickly set in. Later on, as the leaves become fully developed, full exposure to the sunlight is necessary to ripen the growths, and at this stage the plants should receive plenty of water, until the leaves turn yellow and commence to fall, when they should be removed to a light and airy position, in a cooler atmosphere, to rest.

Chysis.—Members of this genus require careful attention as they start into growth, as the flower buds are produced simultaneously with the young growths. Water should be afforded very carefully and sparingly until both are well advanced, as the buds are easily damaged by water; in other respects, this Orchid succeeds well under conditions similar to those advised for Cycnoches, etc.

Dendrobium densiflorum.—This easily-grown, evergreen Dendrobium, in several varieties, is now producing its racemes of beautiful flowers, which will develop well if the plants are grown in a light position in the intermediate house. If the specimens are watered heavily at the roots the flower buds will turn yellow and drop before expanding. As the flowers open, drier and cooler conditions should be given to assist in keeping them perfect over a long period. The pseudo-bulbs should be spread out and secured to stakes in order to display the flowers to the best advantage.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Thinning the Fruits.—This operation demands quite as much study as disbudding. When Peaches and Apricots set their fruits very thickly the trees should be gone over at the earliest possible moment, and relieved of all badly placed and small fruits, repeating the operation in a few days, and leaving only a few over a full crop; this surplus should be removed after the stoning period. The final distance apart to leave the fruits will depend very much, on the strength and vigour of the tree. Overcropping not only exhausts the trees but leads, undoubtedly, to biennial bearing, which is not good culture or satisfactory in the least. Peaches may be finally thinned down to one fruit per square foot of wall surface to obtain the finest specimens, while Nectarines may have two fruits, and Apricots three or four fruits, to the same amount of wall surface.

Pears.—Many Pear trees are blossoming profusely this year, which is not always a good omen, particularly with weak trees, for it is well-known that a superabundance of flowers is a disadvantage in that it wastes energy, to the detriment of the tree and the crop. Where there is a heavy set of fruits on such weak trees, the earliest opportunity should be taken, where practicable, to relieve the trees of all surplus fruitlets. In many cases whole trusses can be spared, and in others the reduction of the trusses to one fruit will greatly relieve the strain.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—As the sun gains power these plants will require greater quantities of tepid water and copious syringings twice a day. If forced under favourable conditions—plenty of light and heat, and liberal ventilation—the fruits will set freely, and if this treatment is continued, the fruits will attain good size and a well-finished appearance. As batches of Strawberries are removed from the shelves in vineries and Peach houses they should not be replenished; light pits in which a moist, warm atmosphere may be maintained should be employed for the successional batches, to guard them against early attacks of red spider. Plants in the early stages, and late in the season, will do much better in pits than upon dry shelves, where watering two or three times a day soon washes all the goodness out of the soil. Late plants, to produce a supply of fruits during May, should be allowed plenty of room, and should be kept close to the glass in a cold pit, or, better still, in a pit with a hot-water pipe running along the front. These pits are well adapted for Strawberry growing, and plants in them should produce remarkably fine fruits and maintain a succession until early varieties are ripe in the open. If the pits are shallow the pots may be placed four inches apart on ashes, or partly plunged; air should be admitted freely in mild weather, and unless the elements are unfavourable, fire-heat may be dispensed with until the plants come into flower, when gentle warmth will be essential, also a free circulation of fresh air to dispel stagnant moisture. Once the fruits have set, fire-heat may again be dispensed with. The fruit trusses should be well thinned, but the pots must not be disturbed, as much benefit will be derived from roots which escape through the crocks into the ashes. Early morning is the best time to water and feed the plants, and very little syringing will be necessary, as early closing to trap the sun-heat will keep the atmosphere sufficiently moist. Early forced plants intended for planting out should be syringed with sulphur water to free them from mildew and red spider, and should be watered freely until required for planting.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Flowering Plants for the Water Garden.—Among flowering plants there are many that may, with advantage, be grown in bold masses, and extremely fine effects are secured if their colours are reflected in the water. Few subjects are better than the tall, purple-flowered Lythrum salicaria var. superbum. For yellow, there is Senecio Clivorum, S. Wilsonianus and S. Veitchianus. When bright scarlet is desired, Lychnis chalcedonica and Lobelia cardinalis will be found suitable, while Rodgersia's, with their large, bronzy foliage, are choice subjects for employment where peaty loam is available. Saxifraga peltata, with heads of pink flowers which are succeeded by large, circular leaves, and Petasites japonicus, are happy on the moist banks of streams and ponds, and Spiraea gigantea, S. g. var. rosea, S. Aruncus, S. palmata and the numerous Astilbe species and hybrids, are all ideal subjects for such positions. The many species and varieties of Trollius are never seen to the best advantage unless planted by the waterside, where they develop a vigour quite astonishing compared to those grown in the herbaceous border. Primulas, such as P. japonica, P. Bulleyana, P. pulverulenta, P. Florindae, P. helodoxa and P. rosea, love the moist edges of ponds or streams and most of them will soon naturalise themselves if conditions are favourable. No planting by the waterside would be complete without large drifts of Iris Kaempferi; these, producing in June and July their large, Clematis-like flowers in conjunction with luxuriant foliage, give a fine effect. They do not like lime in the soil, nor too much moisture at the roots during the dormant season; therefore, if possible, the water-level should be lowered during winter. Iris siberica and its varieties Emperor and Perry's Blue, are also desirable, likewise Iris orientalis and I. o. var. Snow Queen; Plants suitable for planting in water of from three to twelve inches depth are fairly plentiful. A beautiful native plant is to be found in the Flowering Rush, Butomus umbellatus, which grows and flowers freely if planted in shallow water, while Pontederia cordata, a handsome American aquatic, with long spikes of bright blue flowers and erect leaves, is specially suitable for this purpose, as also are Sagittaria sagittifolia and S. gracilis, both of which require plenty of room. Menyanthes trifoliata, with sweetly-scented, pale pink flowers, is a rampant grower and requires keeping in check, while Caltha palustris, the Marsh Marigold, and, for those who like it, the double-flowered form, may also be grown in the shallowest water. In the milder districts no water garden would be complete without good groups of the well-known Arum (Richardia africana); a severe winter such as the last will result in it being cut down, but the roots below the water surface are seldom destroyed, and new leaves and flowers will be produced freely. Scirpus lacustris is uncommon, and is quite effective in shallow water. Shady nooks by the waterside may be furnished with Ferns and various other shade-loving plants. Among the former, besides the noble Osmunda regalis, the various forms of the Lady Fern are most desirable. In such positions also the Himalayan Meconopsis Wallichii, such Primulas as P. sikkimensis, P. microdonta, and P. m. var. violacea; Trillium grandiflorum, and Lilium pardalinum, will be quite at home and be seen at their best.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Camellias.—Although Camellias are not grown so extensively as in former years, yet they are useful subjects for the cool greenhouse. They may be grown in receptacles or planted out in small borders and trained up walls; they thrive best in a house from which frost is just excluded Plants which need repotting may now receive attention. The compost for them should consist of equal parts good fibrous loam and peat, with sufficient broken bricks, charcoal and sharp sand to ensure efficient drainage. Those planted out in borders may receive a surface dressing of a similar compost after a small portion of the surface soil has been removed.

Caladiums.—Corms that have come safely through their resting period should now be shaken out from the old compost and placed in boxes filled chiefly with fine leaf-mould and sharp sand, and when growth is active they may be potted. The weaker-growing varieties should be grown in smaller pots than the strong-growing sorts. During their early stages of growth a moist atmosphere should be maintained and the plants should be shaded from bright sunshine, but once the leaves have developed well they may inured gradually to cooler conditions and stood in a warm greenhouse, where they will keep in good condition for a long period.

Lachenalias.—Success in the culture of Lachenalias depends very largely on the treatment they receive after flowering. Water should be given until such time as the leaves turn quite yellow, when moisture should be withheld altogether and the receptacles placed on a shelf in a cool greenhouse, or in a frame which is fully exposed to the sun. It is most essential at this stage that they should be kept absolutely dry; should moisture come in contact with the bulbs, this will start them into growth and the flowering quality and general health of the bulbs will be impaired.

Primula sinensis flore plena.—Where this old double Primula is grown, the plants will have passed out of flower, and should be prepared for propagating, as this variety cannot be raised from seeds. The bottom leaves should be cut away carefully and a slit made with a sharp knife in each division of the stem, in an upward direction, placing a small piece of crock in each cut to keep it open. The plant should then be packed around with Sphagnum-moss, leaf-mould and sand, to encourage roots to develop. When it is found that roots have formed, the plants should be pulled to pieces carefully and each growth potted singly in a sharp, open compost. I have always found it advisable to stand the young plants in a propagating frame for a short time after potting, but they should not remain in a closed frame for any length of time or they may damp off.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Cauliflowers.—Plants that were raised under glass and pricked out into boxes or frames should now be ready for planting in ground that has received a fair dressing of well-decayed manure. Allow two feet between the lines and plant them eighteen inches apart, watering them well when the bed is finished.

Onions.—If seeds were sown in January, a good stock of fine, sturdy plants should now be ready for hardening off, by being exposed fully, before planting them out. The bed should be prepared for them now; the soil should be broken up finely by forking and then made level and firm—the latter by treading in preference to rolling. So soon as they are hardened off sufficiently, the first opportunity should be taken advantage of to plant them, so as to secure a good ball of soil with the roots, which should be disturbed so little as possible. If decayed manure was placed in the bottom of the boxes when the seedlings were pricked out, very little root disturbance should accrue when planting them.

Runner Beans.—Seeds of Runner Beans may be sown in boxes and germinated in heat, but when the seedlings are about two inches high, they should be transferred to a cool frame, to retard growth so much as possible. The ground for them should now receive final preparation, by being lightly forked and raked, and later, when the seedlings have been planted, no time should be lost in staking them, as the stakes will afford them valuable protection from cold winds and late frosts, which often do considerable damage to seedling Runner Beans.

Cardoons.—Seeds of Cardoons may now be sown. They should be sown singly in three-inch pots and started in a frame. Trenches for Cardoons should be prepared in the same way as for Celery, the after treatment of the two crops in the matter of hoeing and earthing being similar.

Late Potatos.—The ground should be prepared for the late Potatos, and the planting of them proceeded with forthwith. Some varieties give more satisfactory results than others in certain soils, therefore if any doubt exists as to the most suitable sort to grow, several varieties should be employed with a view to determining the best cropper.

Water Cress.—If special facilities for cultivating Water Cress are not available, and a bed is desired, the difficulty may be overcome by planting it in trenches in a shady corner of the garden. The seeds may be sown in five-inch pots and germinated under glass, planting the seedlings out after hardening them off, and keeping them damp by spraying them overhead occasionally. By this method a good crop of Water Cress may be secured.

Lettuces.—The Lettuce seedlings in boxes, so soon as they are large enough and before they become spindly, should be planted out. When planted, they should be given a thorough watering.

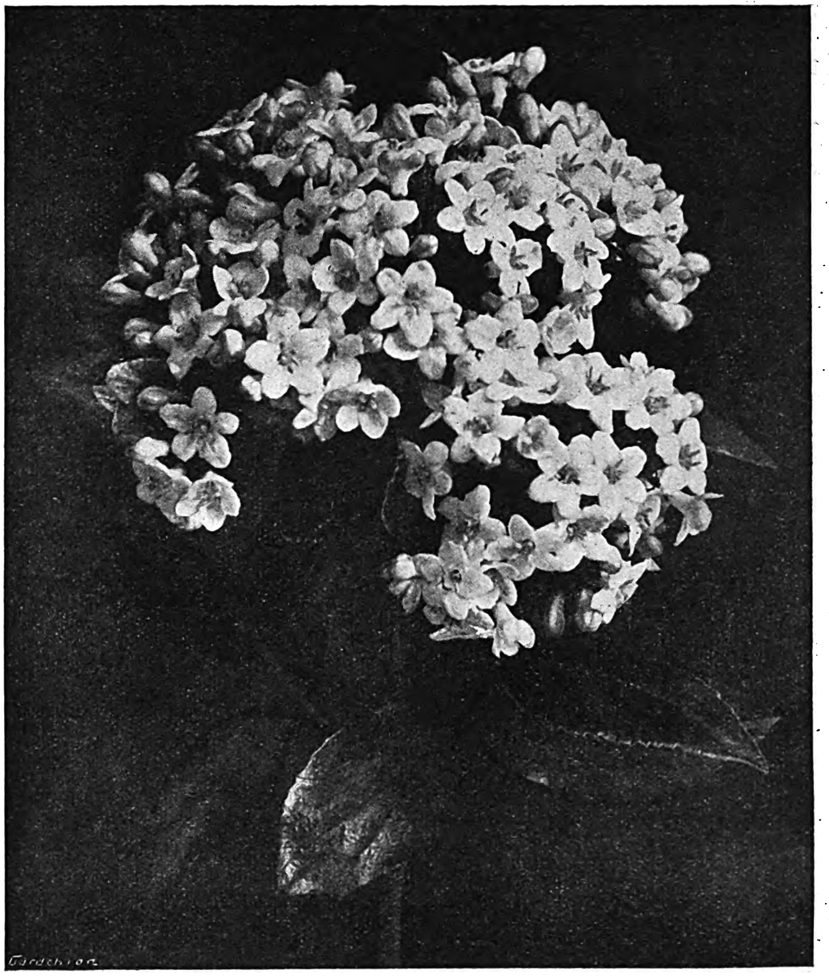

FIG. 148.—VIBURNUM BURKWOODII.

R.H.S. Award of Merit, April 9. (V. utile x V. Carlesii). Flowers white, fragrant.

Shown by Messrs. Burkwood and Shipwith (see p. 285).

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Vegetables.—Early Peas should be supplied with stakes or other supports before they begin to fall over. Cultivate along the rows on both sides with a fork and draw a little soil up to the plants before staking them. If trainers are used, a few branches or twigs should be placed in the centre of the row to support the plants until they take possession of the wires. If the seeds have germinated well it may be necessary to thin the seedlings severely prior to staking. Parsley raised in boxes may be planted out now if well hardened off; in fact, it is inadvisable to delay this operation, as the fairly cool conditions generally obtaining in April enable the plants to establish themselves before protracted dry weather occurs. Deeply-trenched ground is best for Parsley, and where drying off in summer is prevalent, leaf-mould incorporated with the staple soil is advantageous; lime in some form should also be applied in such cases, and at this season air-slaked lime in powder form is safest. As seedlings of all kinds of vegetables make their appearance, hoe frequently between the rows with the Dutch hoe to aerate the soil and prevent weeds from making headway. The Planet Junior Hoe or, in small areas, the Buco cultivator, should be used between crops of Potatos, Brassicas, Seakale, etc., alternately with the Dutch hoe.

Peaches on Early Walls.—As the young growths appear on these trees no time should be lost in removing part of the unwanted or misplaced shoots. Those facing to or directly away from the wall, should be removed at the first operation, and at intervals of five or six days the remainder should be thinned until the requisite number only is left; generally a leader, and one at the base of each shoot, on its upper side. Should mildew make its appearance, spray at once with a very weak solution of lime-sulphur. I find one in one hundred effective; if used stronger, many of the soft young leaves drop.

Seedlings.—Any seedlings in boxes and frames should be kept growing freely by frequent stirring of the surface. Remove all weeds and keep the plants dwarf by pinching or cutting them back where practicable, as in the case of Lobelia, Alyssum, Verbena, Ageratum, etc. As the seedlings approach planting size remove those in boxes to the open and harden them off, but have protection at hand in case of night frosts. Those in frames should have the lights removed or drawn back entirely.

INDOOR PLANTS.

ASTERS AS POT PLANTS.

Asters belong rather to the flower garden than the greenhouse, but as they are valuable for greenhouse and conservatory decoration when grown well in pots, a few words on their cultivation for this purpose may not be out of place at the present time. It is important that the plants should be grown under the most natural conditions possible during the whole period of growth, thus artificial heat should be avoided, and the plants should be given cool, buoyant atmospheric conditions. The seeds may be sown in April in a cold frame, and more satisfactory results are obtained by growing the plants on in cold frames, where they may stand on a cool, moist bottom, than by placing them on a stage in a warm house.

Asters require moderately rich soil to do them justice, and the compost in which they succeed best when in pots is three parts good turfy loam and one part decayed manure. Five-inch or six-inch pots are suitable sizes, growing two plants in a five-inch, and three in a six-inch pot. The pots should be well-drained and filled moderately firmly with the prepared compost, when the seedling plants may be pricked out near the edge as required. The pots may then be placed in a cold frame or plunged in ashes outside. So soon as they are filled with roots, abundance of water and occasional doses of dilute liquid manure will materially assist the production of good specimens. When the flowers begin to show colour the plants may be taken to the conservatory, where they make a bright display for a considerable period. The best for pot culture are the Chrysanthemum- and Paeony-flowered sections, but the Single-flowered types also make graceful and highly decorative plants. *W. A.*

ORCHID NOTES AND GLEANINGS.

HAEMARIA DISCOLOR.

This member of the Order Orchidaceae is rare, and is seldom seen in cultivation. The white flowers are three-quarters-of-an-inch across and have a lemon-yellow blotch in the centre of the lower lip; they are borne in an erect spike, which is furnished with a number of crimson-coloured bracts.

The leaves are dark olive-green on the upper surface, with a thin white mark down the centre of each, while the under surface is reddish, which fact gives to the plant its name Haemaria. The entire leaf has quite a velvety appearance and is somewhat fleshy.

It is advisable to make up fresh specimens of this Orchid each year. This is done by taking cuttings that have a small number of roots already attached, and putting them in shallow pans. The compost should be one of well drained peat, sand and a little loam. The plants require a liberal supply of water at the roots during the growing state, and will commence flowering early in January.

Haemaria discolor is best grown under a bell-glass, which should be stood on three or four inverted sixty-sized pots. *F. H. Wright, University Botanic Gardens, Cambridge.*

RENANTHERAS.

Few Orchids are more easy of cultivation, or more floriferous, than the Renantheras, or Scorpion Orchids, as they are termed. The stems are terete, woody, and usually about a quarter-of-an-inch in diameter, and they emit long, greyish roots from the nodes. They often attain to a length of twenty-five to thirty feet. The leaves are coriaceous and oblong, while the flowers, which are of large size and brilliant colour, are produced in large panicles. The species here mentioned are found in the Malayan Chinese region.

R. Arachnites (syn. Aracnanthe moschifera) has flowers three inches across, the sepals and petals green, with blotches of brown, and the lip white. Owing to the curved lateral sepals and the straight upper one, this species is commonly known as the "Scorpion Orchid." It is a native of Malaya, and is cultivated to a large extent. It possesses a strong, Musk-like scent.

R. coccinea is a species from Cochin China. It is a vigorous plant but rarely exceeds twelve feet in length, while it produces large and much-branched panicles of numerous scarlet flowers, mottled with yellow; these are about two inches in diameter, and have oblong, spathulate and obtuse lateral petals.

R. Maingayi is not so fragrant as the others, and it has smaller leaves, which are seldom more than five inches long and one-and-a-half inch wide. The flowers are arranged in loose panicles and vary in colour. The sepals are linear-oblong and about one-and-a-half inch long, while the petals are curved at the apex and mottled pink or white, the lip being broad, pink, with darker stripes, and sometimes yellow blotches on the side lobes. It is a very beautiful species, but not so floriferous as the former. R. Maingayi is found in Malacca, Jahore, and in other parts of the Malay Peninsula.

R. matutina is dwarfer than the preceding species; it has speckled stems one foot to two feet long, clothed with narrow, ligulate leaves. The scape is about fifteen inches long and often branched. The flowers are loosely disposed about twenty to each spray; they are about two inches across, red or orange, spotted with darker colour, the lip being white with a red centre. It is found in Perak, but is more common in Borneo.

These Orchids are very popular for house decoration, as the flowering sprays last a long time when cut.

They may be propagated by cuttings taken from the growing ends of the stems. *F. S. Banfield, F.L.S., Malaya.*

ALPINE GARDEN.

ALPINE CAMPANULAS.

I have read with the keenest pleasure the admirable article on "Alpine Campanulas," by *M. W.* (p. 263), and am in general agreement with your able contributor. In the course of the article, he refers to the question as to whether C. turbinata is, or is not, a distinct species, or only a form of C. carpatica. It is a question which has given rise to much discussion, and still remains unsettled. I am always inclined to the view that it is either a species or a natural hybrid of unknown origin. It is constant in its ways, and one noticeable feature of the true C. turbinata is that it has never more than a single flower on a stem; while the foliage is hairy, that of C. carpatica being smoother. These features are constant, and seedlings seem to maintain them, so well as plants propagated by division. C. turbinata, true, is a much choicer plant than C. carpatica, and it is a pity that the true plant is so scarce, and that C. carpatica is substituted for it in many nurseries. I do not recollect ever seeing any one tell where C. turbinata is to be found wild. This might settle the question, or, at least, help to do so, as we might learn if C. carpatica and C. turbinata are found together or near each other. C. turbinata is one of our best alpine Campanulas.

By the way, *M. W.* appears to retain the name of C. pusilla for the Campanulas usually grown under that name, instead of adopting C. Bellardii after the fashion of the late Reginald Farrer, and as he does in the case of C. Bellardii Miranda. *S. Arnott.*

PRIMULA SUFFRUTESCENS.

This is an interesting plant inasmuch as it belongs to the sub-shrubby class of Primula. A native of the central Rockies, and almost the sole representative of the Cuneifolia section of Primulas, this species has a semi-prostrate habit, the woody branches trailing about the ground. These are sparsely furnished with tufted rosettes of dull green, glossy leaves which are long and narrow, widening at the tip like an elongated wedge. From the centre of these tufts a slender flowering stalk appears in early summer, this terminating at a height of about six inches in a small, loose head of pale rose-pink flowers, each with an orange eye. There is a suggestion of P. rosea in these blossoms, but the latter have not so brilliant a colour as the waterside plant.

P. suffrutescens is a plant that might be more often seen in gardens, for it is hardy and not really difficult. A light, gritty soil (or sandy peat) which does not get too dry in summer suits it. Full sun is desirable, as is freedom from tree-drip and excessive winter wet. The only troublesome part about the cultivation of P. suffrutescens is in propagation. It does not offer any opportunity of division, seeds do not ripen with me, and cuttings do not root readily. Still, the latter are by no means impossible, even without bottom heat, and another means of securing fresh plants is by layering some of the branches in very sandy peat. *J.*

ARENARIA BALEARICA.

There are some plants which unaccountably find their way into gardens, and yet are appreciated so much as to rank with those indispensable treasures for which comparatively large sums of money are paid. The Balearic Sandwort is one which commands attention, for, although the reverse of pretentious, it has a flair for cropping up in unexpected places and from sources of unknown origin. Once in possession of a suitable situation, this species need not be lost; as a "garden escape" it is pre-eminent, and fortunately it frequently strays into a good home. People who are actively engaged in horticulture are continually being asked to name the plant, sometimes with the aid of living material, but more often from a vague, although quite enthusiastic description, such as "a perfectly delightful creeping plant with small leaves and white flowers."

Scattered about in rock gardens all over the country, this frail little gem has settled down wherever possible. Barely discernible during the dull days of winter, it covers the rock in early spring with a wandering, thread-like network of stems, set with minute, rounded, fresh green leaves, and later on dotted with a multitude of tiny white stars, barely one-eighth-of-an-inch across and borne on half-inch stems that are fragile, yet wiry enough to hold the blossoms well above the mat of leaves. The flowering season extends right through the summer months, from late spring until October.

A. balearica appears to be most at home in a moist position, but it appreciates sunlight, and will grow profusely on either limestone or sandstone. Although it does not require much soil in which to grow, it will at times become so luxuriant as to clothe the rocks with a thick, green sward and then spread out over the soil until it becomes a danger to other plants. In such circumstances, it is fortunate that A. balearica does not object to drastic restriction; it should certainly be kept within bounds, but not destroyed unless it is taking possession of the whole garden. In fact, this charming native of the Balearic Islands, which is so accommodating and free-growing in our climate, should be planted with discretion, and is best kept to that part of the rock garden where the choicest varieties are not grown, and where it can ramble about more or less at will. *L. B. C.*

PLANTS NEW OR NOTEWORTHY.

WATSONIA BEATRICIS.

To those who only know the white or rose-coloured species of Watsonia, the subject of this note will be something of a revelation, for the colour of the petals is as uncommon as it is remarkable. It is described in the *Botanical Magazine*[*] as perigone-scarlet, with the limb (of the flower) verging to orange, and by Matthews and L. Bolus[†] as rich apricot-red;

---

[*] Vol. CLII, t. 9139.

[†] *Ann. Bolus Herb.*, IV, p. 52 (1926).

while Mrs. Dudley Ryder, whom we have to thank for the introduction of the plant to this country, describes it as a hot, dense apricot.

W. Beatricis (Fig. 149) is a new species named after Beatrice Hops, who found it in the district of George, Cape Colony, and it was recently published by Matthews and Bolus *. The plant first flowered in this country early in September, 1925, in the garden of the Hon. Mrs. A. Dudley Ryder, at Durns, on the northern shore of the Solent, between Lymington and Beaulieu, and was sent to the writer to be submitted to the R.H.S. Floral Committee as Watsonia Pillansii. In view, however, of the beauty of the plant, and its novelty, it was placed in Miss L. Snelling's hands in order that a drawing might be made of it, and next day was sent to Mrs. Bolus, the distinguished Curator of the Bolus Herbarium at Kirstenbosch, who was then working in the Herbarium at Kew. Mrs. Bolus recognised the plant as W. Beatricis, which has flowered for several years in the National Botanic Gardens at Kirstenbosch, South Africa, but had not been formally published.

When Mrs. Ryder first saw W. Beatricis on February 6, 1923, it was in full flower near George, in low-lying ground, growing in coarse grass, and sometimes among rushes, but not in boggy places. The seeds were not then ripe, but after her return to England, Mrs. Ryder received seeds of the Watsonia from Mrs. Vincente, who lives at George. These were sown at Durns in May, 1923, and plants flowered in 1925. It was from one of these plants that the plate in the *Botanical Magazine* was drawn by Miss Snelling, and the description prepared by Dr. Stapf.

W. Beatricis grows freely on the veldt between George and Knysna, and in 1927, Mrs. Ryder saw the species in flower again, at the Cape, towards the end of December, but owing to the great drought which prevailed in South Africa at that time, the foliage, which is peculiarly beautiful, was browned and the plants were stunted. A peculiarity of the species is the solid, waxy character of the petals, which are not in the least of papery consistency like those of Watsonia rosea, for example. The flowers are set on the stem with a mathematical regularity approaching that of an ear of Wheat.

The hardiness of the Watsonia genus in general in Britain has long been suspect, and probably rightly so, or else some members of it would be more often seen outside greenhouses than they are. One or two are perennial in maritime gardens on the south and west coasts, and in parts of Ireland, but even W. Ardernei seldom stays long in inland gardens. This may, perhaps, be because it begins to grow anew in the autumn soon after the flowers have withered, so that the new growth is at the mercy of winter frosts of more than a few degrees. Like many South African plants, too, it probably finds our average allowance of sun too little for its comfort, and it certainly enjoys itself in hot summers like those of 1911, 1921 and 1928. In that respect it is like Amaryllis Belladonna, and a good flowering season for one is usually equally appreciated by the other.

Mrs. Ryder tells me that W. Beatricis has come through the severe winter successfully in a boggy place in her garden, where frosts of so much as 21° were frequent in March. A curious point about this Watsonia is the remarkable way it has adapted itself already to our climate. At the Cape, Mrs. Ryder found the species in bloom in February, yet the plants she has raised here from seeds of the February-flowering Cape plants, do not come into bloom until September. At the end of March corms of Mrs. Ryder's plants were just beginning to push up new growths—a few weeks after their relatives at the Cape had finished flowering!

There is something about those members of the family that we know here which leads one to suppose they may be calcifugal, and when they flourish in Britain it usually seems to be in humus.

The illustration (Fig. 149) has been reproduced from the drawing prepared by Miss L. Snelling for the *Botanical Magazine*, and is published by courtesy of the Royal Horticultural Society.
A. Grove.

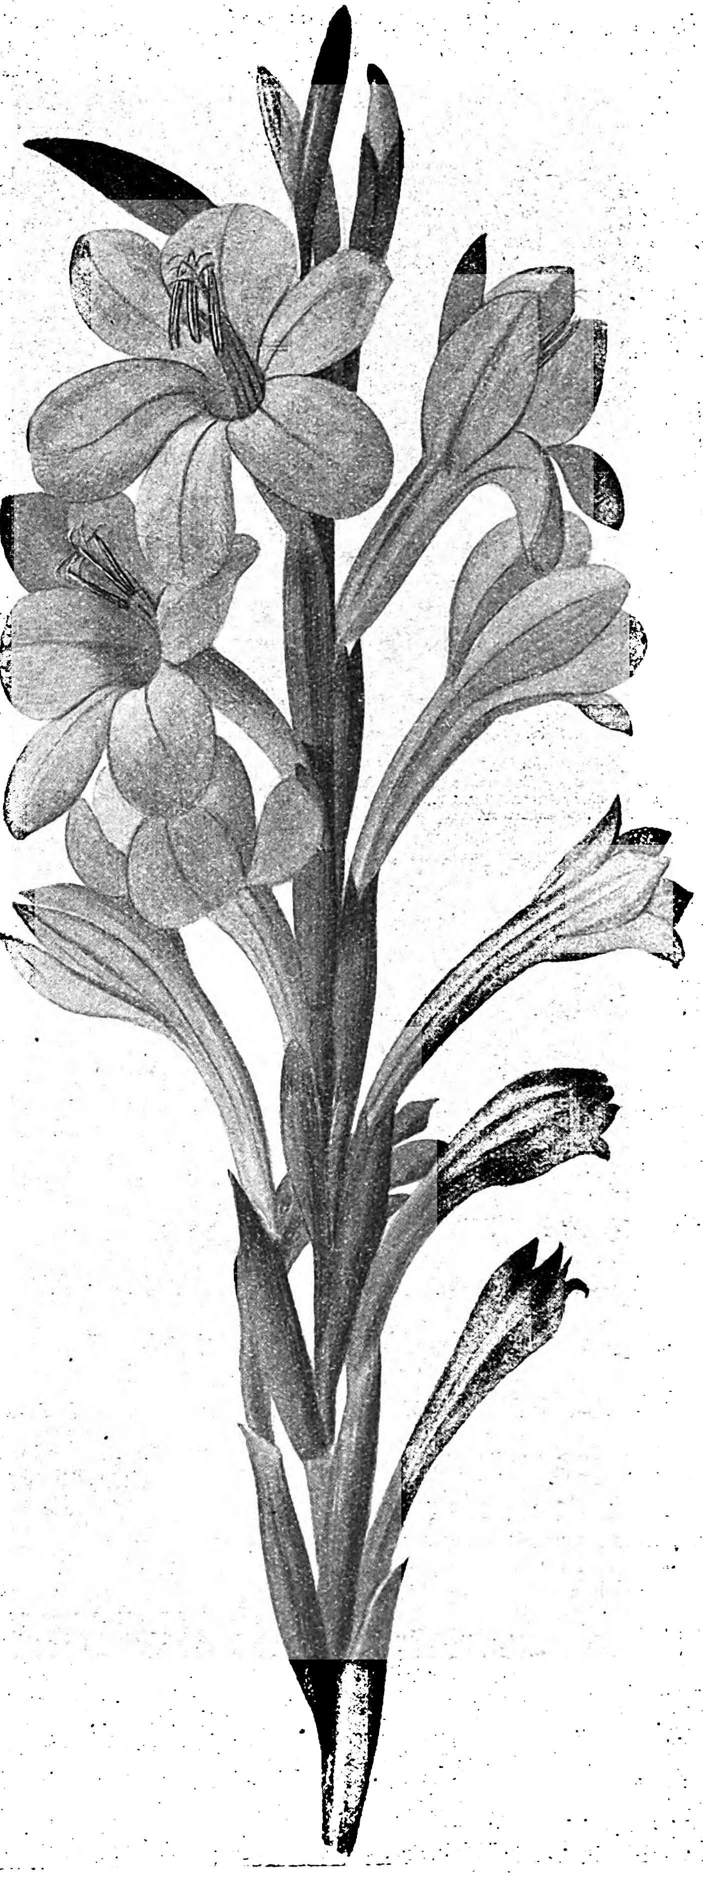

FIG. 149.—WATSONIA BEATRICIS.

From a drawing by Miss L. Snelling, of a plant grown in the Hon. Mrs. A. Ryder's garden, September, 1925.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

THE GARDEN POLYANTHUS.

When searching for particulars concerning the origin and history of the Polyanthus, I made the following notes:—

Dorstenius' *Botanicon*, 1540, contains a record of "Primula veris eo decocto si paralytica membra inungantur, ualde prodest"=If this is boiled down and palsied limbs are annointed with it, great benefit will result.

Most of the old herbals (the earliest one printed was in 1470) allude to the Primrose as Herba paralysis.

The greatest and most typical of sixteenth century botanists, Leonhard Fuchs, 1542, described as the third of the fathers of German botany, makes no mention of Primula veris or of the Tulip in his botanical work.

There is no description of a plant exactly like the Polyanthus by Gerard or Parkinson, or in the works of earlier herbalists. Gerard, in his *Herbal*, 1597, does not differentiate the plant from the Primrose; he notes Cowslips, with coloured flowers, Birds-eine and Bears-ears; Primula Auricula with leaves said to resemble Bears' ears, and states they are grown in our London gardens. He alludes to the use of the Primrose as a remedy for paralysis.

Parkinson (*Paradisi*) in 1629, also mentions Birds-eine and Bears-ears, Primula Ursi; some with colour tending to purple, yellow in the middle, the small yellow circle resembling the eye of a bird; and some of red colour with a whitish eye. Thus we have a note of the antho-cyanin pigment in the petal.

In *Hortus Eystettensis*, 1613, Bazil Besler, describing the plants of the famous Botanical Garden at Eichstadt—founded in 1609 by Abbot John Conrad von Gemmingen, and destroyed in 1634 during the Thirty Years' War—describes the Primula veris pratensis as Herba paralysis; Polyanthus—Primula veris hortensis floro gemimo; and Auricula Ursi as Primula veris, Albo, Purpurea Luteo. There are three illustrations.

John Rea, in 1676, writes of Primula veris and paralysis, and Bears-ears—nobler kinds of Cowslips.

Worlidge, 1683, in the *Art of Gardening*, states: "They delight in rich soil and shade, but not drip of trees, winter in sun, summer in shade. Defend them from wet in winter, but they endure all the cold very well. In your election of them, it is better to trust your eye, or confide in an honest gardener, than in the lame descriptions you meet withal."

There is no indication that Salmon, 1711, knew the Polyanthus as a herb, although he describes a wild hybrid Oxlip, and a red Primula from Turkey; he notes Primula veris major—the Cowslip; Primula veris minor—the Primrose; and P. v. pratensis—the Oxlip. He, too, calls the Primrose, Herba paralysis.

In Mortimer's *Husbandry*, 1716, I find Auriculas, Cowslips and Primroses mentioned, but not Polyanthuses.

Bradley, 1719, in *Improvements in Gardening*, states there are two kinds of Polyanthus, the Primrose kind and the Cowslip kind; he writes of a Polyanthus called Feathers, with blossoms split. He described the perfection of the Auricula in terms even George Glenny might not have found amiss. He wrote: "Auriculas increase so fast, wise men decrease so fast; in a short time this tribe of plants will want men of note to take their names from." He mentions "The Pride of the Garden," of which one root sold for twenty guineas. There is evidence of a Polyanthus "boom" in 1728.

In *The Flower Garden*, of Furber, 1734, the Polyanthus is depicted as of scarlet colour, with a yellow eye and yellow edge, called "Goldfinch." Of Auriculas, some called "Painted Ladies" and one "Royal Widow" sold for ten guineas. He observes the plants may come with thrum eyes one year and pin eyes the next year—I wonder!

J. W. Weinmann, 1737-45, in *Phytanthoza Iconographia*, gives drawings of Auricula Ursi, green edges, perfectly round eyes, red body colour, some dense in shade but mostly striped; and one green, but of starry shape. The Polyanthus he describes as Primula veris—a Primrose clearly.

P. Millers' *Dictionary*, 1752, gives long instructions for care and growth and method of seed-raising: "Sow in December, lightly cover, place in morning sun until 10 o'clock, by no means expose to the heat of the day—one day's sun will kill the young plant.

Eden, 1757, considers the Polyanthus as universally known as any that can be brought into a garden.

The profound and philosophical clergyman, Harvey, 1757, meditates on the Polyanthus with its sparkling beauties, and turns to the Auricula—"with an eye of chrystal and garments of the most glossy satin exhaling perfume and powdered with silver."

In 1761, Polyanthuses were a guinea a root.

Mawes' *Gardeners' Kalendar*, 1767, recommends the sowing of a portion of the seeds in August, but the main part in February.

J. Maddock, in the *Florists' Directory*, 1792, accurately describes the Polyanthus and gives a plate of a perfect pip with a description of the properties of a fine Polyanthus, full instructions for its culture and propagation, and many sage hints as to its care and treatment.

In 1815, Emmerton wrote a treatise on the Auricula. *Flora Historica*, Phillips, 1824, considers "The Polyanthus may justly dispute the prize of beauty with any European flower." He writes of wild Primrose plants in Dr. Buxton's garden at Greenwich; some produced flowers with a scape—not an infrequent occurrence, by the way. He also notes that a change of colour from sulphur to red tint was frequent and describes the "Polyanthus of unnumbered dyes."

The Polyanthus is of mixed descent, of garden origin, and essentially a British flower, partaking more of the nature of the Primrose than of the Cowslip. Professor Hislop Harrison considers the Primrose strain is more potent than the Cowslip strain. Although Parkinson classes the Auricula as a Cowslip, called Primula veris elatior, or taller Primrose, to distinguish it from Primula veris humilis or dwarf Primrose—another old name is Mountain Cowslip—Linnaeus joins the Auricula to the Primula veris (Primrose), and gives long instructions for its care and growth. Most of the authorities classify the Polyanthus as a Primrose, which seems most reasonable, and they call the Oxlip, Primula elatior. *C. W. Needham, Hale.*

CHILE AND THE ANDES.

No. X.

We had a busy week in Santiago. We called upon Professor Fuentes, who was both courteous and helpful, giving us much time and information and putting the Museum Herbarium and Library at our disposal. We called upon Senor Maldenado, of the Ministry of Agriculture, who gave us copies of his work upon the trees of Chile, and conversed with us in English, and we with him in Spanish and French, only twenty-five per cent. of which was, I am sure, intelligible to any of us, although all was very cordial and friendly. We discovered a second-hand book shop where was a copy of Gay's wonderful *History of Chile*. It filled several yards of shelf, and the price was £25, and cheap at that, but we did not buy it; too bulky to cart about, and besides, there it always was when we specially wanted to look up botanical finds, and the owner of the shop did not seem to mind how often we came!

We tried to buy revolvers and to purchase the "world's biggest tortoise." We made no botanical discoveries worth mentioning in Santiago, but in the way of fauna, we became acquainted with the abomination that leapeth by day, and worse still, with the horror that troubleth the night watches. With regard to the revolvers, we were somewhat worried. An English friend who had lived in Chile for a good many years gave us a grave warning—told us we really must not go pottering and poking about in the hills and mountains and country places armed with nothing but trowels. He told us shocking cases of foreigners who had strolled into the country, and been found later at some lonely spot, ripped to ribbons all for the sake of a few pesos in their pockets. Advice from other quarters was conflicting, but the result was that we decided that perhaps we had better be on the safe side, especially after seeing a rather nasty street scuffle. We went, therefore, to choose the revolvers at an ironmongers. Mine was a workmanlike brute like a T-square; but on stating we would have them, we were asked for our permits to carry arms, which we had not, and without which we could not buy. We called at the War Office to obtain permits, but decided that we could not settle down in Santiago for the indefinite period that seemed necessary, and so were saved the cash and great anxiety that the weapons would have cost us The tortoise we met when looking for somewhere to have lunch. A little crowd had collected on the pavement and we thought there must be a dog fight or a street accident. I pushed in to have a look, and there, instead of a dog fight, was the "biggest tortoise in the world." On the wall above him hung a crude poster announcing "Tortoise Soup to-day." I do not pretend to be a testudologist, but I recognised him as one of the almost extinct species from the Galapagos Islands, and far bigger than anything in the London Zoo, so my companion and I decided that at all costs we must save the tortoise from the soup and send him to the Zoo. We lunched at the restaurant—which was excellent—and opened negotiations for the purchase of the tortoise, without much success. The pro-

---

* Previous articles on Mr. Clarence Elliott's expedition were published in our issues of November 12 and 26, December 10 and 24 Vol. LXXXII; January 7 and 28, Vol. LXXXIII; July 28, Vol. LXXXIV; March 28 and April 6, Vol. LXXXV.

rietors imagined, I think, that we were setting up an opposition restaurant and wanted him for opposition advertisement. We were leaving Santiago for Coquimbo next day, so we instructed an agent to buy and hold the tortoise for us, naming a very long price as our maximum, and at that we had to leave it, feeling pretty sure of success.

We left for Coquimbo by train on September 17, the eve of Chile's great national fête day of independence, and we arrived in Coquimbo the following afternoon. It was an exceedingly interesting journey to us, although somewhat slow and crude. But it is a journey which folk who live in the country avoid if they can, prefering to go by sea. At one point a high mountain pass has to be crossed, and here the train has been known to come unstuck in the middle, with hateful results for the rear portion. At every tiny wayside station there were flags to celebrate the great September 18. Children came out and sang patriotic songs, and our engine was decked with flags and flowers. At one station I got down and went forward to botanise on the engine. I had identified Centaurea chilensis, a handsome, cream-flowered species, smelling of goat; two forms of Leucocoryne, and Pasithea coerulea, when the train dashed off without warning, and I only just managed to leap on to the guard's van at the rear, where I was marooned for over an hour, missed lunch—but shared the guard's.

Coquimbo is a deadly little town—I hate writing this, for we received much charming hospitality there. It sits on the shore of a rocky promontory which forms one extremity of a lovely bay. The railway runs down the main street, and above this street, at right angles to it, lesser streets run up the rocky hillsides to unbelievably squalid looking slums. At the principal hotel we were given a gaunt room with two pretentious beds, merely to look at which made one go goose-skinned, and a grimy plush sofa on which, instinctively, one did not sit. To be fair and honest, however, our nights here were less disturbed than we expected.

A road runs from Coquimbo around the beautiful bay to Serena on the other side, ten or twelve miles away, and soon after arriving we boarded a motor-bus and set out on this route, in order to get into the country. Four or five miles out we got down and walked inland, and soon got away from cultivated land among the low, rocky hills. At once we began to find interesting plants. In a small plantation of young Eucalypti we came upon a new Leucocoryne, more sensational even than the blue one. A fine deep lilac it was, shading to a lurid blood-red centre. But it was scarce, very scarce. We only found a dozen or so, and did not secure all of these. The bulbs were deep down in very sandy soil and were extremely difficult to get. There was one drawback to this brilliant Leucocoryne, which, by the way, we never found anywhere else, and that was a strong odour of Garlic when the plant was handled. Several other species have the same defect, especially one of the white ones which has extremely fragrant flowers. We found our blue Glory of the Sun near the lilac and red species, but not very plentifully.

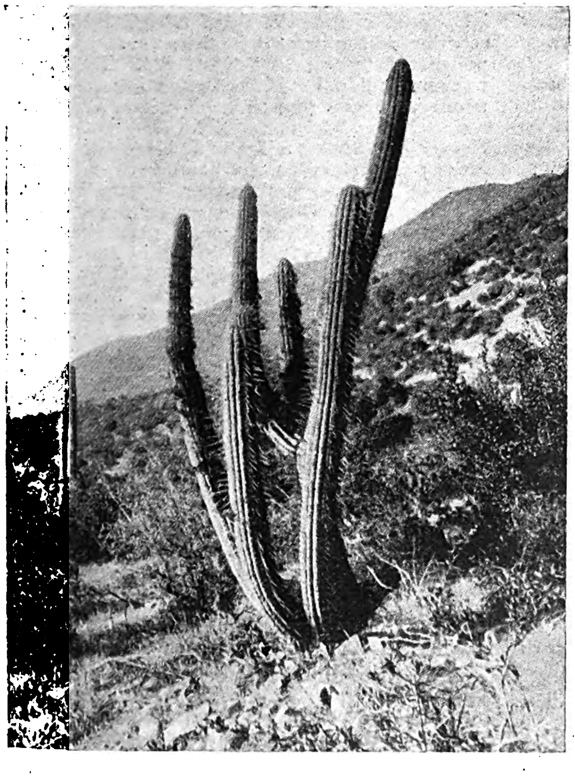

FIG. 150.—CEREUS ON THE HILLSIDE AT COQUIMBO.

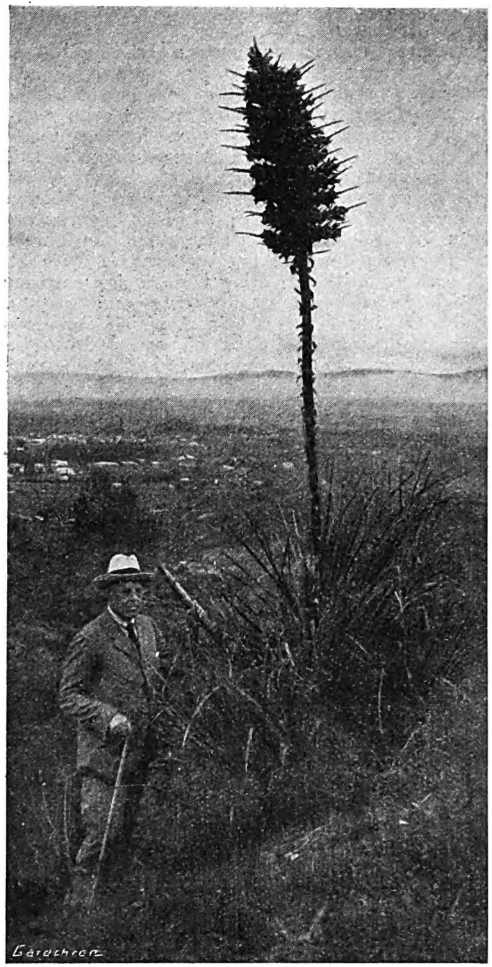

FIG. 151.—PUYA CHILENSIS ON THE HILLSIDE ABOVE VILLA ALLAMAND CHILE.

An interesting plant was Plumbago chilensis, a wiry, sub-shrubby species with dark Oxford-blue flowers. It grew in rocky places, with rather the habit of Ceratostigma Willmottianum, from three to four feet high, and was almost, although not quite, a really good plant. Sometimes one thought it was delightful, and then at other times one would think it was hardly worth collecting, but I did collect and send home seeds, although I have not yet heard of them germinating anywhere. I think the chances of it turning out hardy are remote, and if not hardy, it would be hardly worth while. Even more interesting than the Plumbago was Oxalis gigantea (Fig. 152). This extraordinary Oxalis makes a large, woody bush, often so much as six feet, eight feet, or even ten feet tall. Its erect, slightly branching stems are thickly furnished from top to bottom with short spurs, carrying rather fleshy, green leaves and countless golden blossoms. The trunk is often two or three inches in diameter at the base, and I cut and brought home a stout walking stick of it. Among one of the consignments of specimens sent home to Edinburgh Botanic Gardens, I enclosed a short length of the woody stem of Oxalis gigantea as a curiosity. It took over four months to reach Edinburgh, and there it was pounced upon by Mr. Stewart, who, seeing in it scope for a miracle, set to work to propagate from it! When last I heard from Edinburgh, more than a year after I had collected it, I was told that this piece of Oxalis timber was bursting into leaf!

A very charming plant growing quite plentifully in this rocky country was a shrubby Solanum species (C.E. 11). It formed spreading bushes, with ascending stems four feet to five feet high, which carried panicles of violet flowers in enormous quantity. Both in habit and in flower it is much like S. crispum, although the leaf is pinnate. Finding it in full flower, I hardly hoped to get good seeds, but after long search we found a plant with last year's fruits still hanging. Lt.-Col. Messel (gr. Mr. Comber) showed this Solanum at the R.H.S. meeting of August 28, when it received an Award of Merit, as a tender shrub. That, I think, is how it had better be classed, although I should have little fear for it in the open in mild districts. At Mrs. Carl Holmes' garden at The Node, Welwyn, Mr. Penton recently showed me pot plants of it in a cold frame, whose pots of soil were frozen stiff, yet which were sprouting vigorously from the base. This Solanum has been identified at Kew as S. pinnatum (Cav.). *Clarence Elliott.*

(*To be continued*).

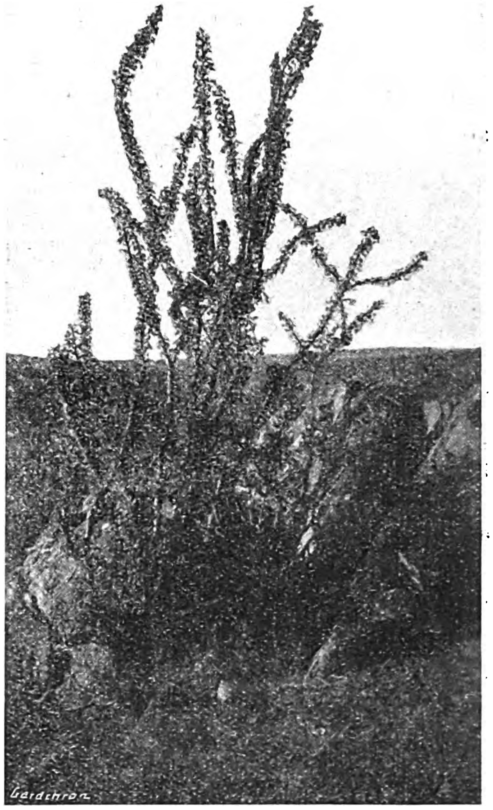

FIG. 152.—OXALIS GIGANTEA AT COQUIMBO.

INVESTIGATIONS ON THE SHAB DISEASE OF LAVENDER.*

Investigations on the shab disease of Lavender have been carried out at the Cambridge University Botany School, and on the grounds of growers of Lavender on a large scale at Worthing and Hitchin.

Field Observations.

Extensive field observations have been continued to determine the point of origin of the disease in the plant. These have now made it quite clear that there are two main methods by which infection can occur (1), through the leaf axils on young developing shoots up to the time when the bark is formed on them; other parts of these shoots are also liable to infection, but infection most commonly occurs in the leaf axils; and (2), through wounds made at the time of cutting the crop, or in various trimming practices carried out with shears.

Field observations have also shown that the fungus which causes the disease grows saprophytically on White Goosefoot (Chenopodium album), which is a very common weed in Lavender fields. The fungus has been isolated and grown in pure culture from this source, and Lavender plants have been inoculated with the cultures thus made. The inoculated Lavender plants became diseased in the same way as those inoculated with the fungus from Lavender. This fungus has not been found growing parasitically on Chenopodium album, nor has it been found growing saprophytically on any other weeds in diseased Lavender fields.

Culture Work.

The fungus which causes the disease has been grown in pure culture, and it has been identified as Phoma lavandulae, Gabotto.

Experiments with hanging-drop cultures have shown that when once the spores have been exuded from the pycnidia they cannot retain their capacity to germinate for more than 114 hours in a dry atmosphere, and begin to lose their viability after sixty-four hours under moist conditions at 15°C. The pyncidia, on the other hand, are highly resistant to a wide range of environmental conditions, and the spores that they contain do not lose their viability for at least a year, and probably much longer.

Inoculation Experiments.

Inoculations of healthy Lavender plants carried out at monthly intervals throughout the year have shown that under suitable conditions infection can take place at any time of year, although least readily in January, and most readily during the spring and autumn. Infections can occur in any month, both in wounded and unwounded plants, but always take place most readily if fresh wounds are present. This is specially so in the winter months. In all cases there is a long lapse of time, usually ranging from two months to as much as a year, between the time of inoculating and the first appearance of disease symptoms, so that a plant may appear to be healthy while the fungus is in a latent condition.

Other experiments have shown that wounds freshly made in August and March are liable to infection only until they are a month old.

Inoculation of different varieties of Lavender have shown that, while most varieties are about equally susceptible to disease, the variety Dwarf French appears to be completely immune. This variety is stated to be of no value in the manufacture of perfume. Lavandula dentata is also immune from the disease.

Inoculations through leaf axils on young stems have shown that infection can occur at these points, but that wounded leaf axils are more liable to infection than unwounded ones.

Control Measures.

Field observations have made it clear that if shab disease becomes established in any field, pycnidia lie about on dead twigs, and on Chenopodium album, and the ground becomes "Lavender sick." Hence, a period of at least one year should be allowed to elapse before replanting any such area with Lavender.

Cuttings should be extremely small and selected only from healthy plants. Minute cuttings in a light soil in a glasshouse have been found to root more readily and to grow more rapidly than larger ones. In one instance many thousands of cuttings which were taken in this manner from a badly diseased stock have so far shown only a small percentage of infection.

A large scale experiment in which bushes were trimmed drastically with shears early in March, resulted in a decrease in the spread of the shab disease by one-half during the ensuing summer as compared with unclipped control plants. Evidence has been obtained which indicates that the result would have been even more satisfactory if the clipped plants had not become infected from the unclipped control rows in their immediate vicinity. Flowering was delayed for a fortnight or three weeks.

Lavender should be afforded clean cultivation, and special care should be taken to eradicate Chenopodium album.

Experiments with manurial treatments have not had time to give conclusive results. *J. R.*

---

* Abstract of a paper by Mr. C. R. Metcalfe, read before the British Mycological Society on March 16.

NOTICE OF BOOK.

Nature in Field and Meadow.*

The above is a naturalist's book of light reading, which some would skim through in the course of a journey from London to Brighton by train, although little of the instructions would be remembered. The beginner, at least, would have to take the book to the field and try to discover some of the objects named by the aid of the descriptions and the illustrations, which are line drawings, with the exception of that on the cover and the frontispiece, which are coloured. There are twelve chapters in the book, dealing with the fields and meadows of England, about the soil, trees and shrubs, grasses, lesser and greater flowers, four-footed inhabitants, smaller and larger birds, butterflies, and miscellaneous creatures of field and meadow. The author must have made many excursions from his home in the first garden city to make observations on wild nature.

The first chapter deals with antiquities, including flint implements of the palaeolithic age, and others down to Roman times, so well as fossils from the chalk. In dealing with the soil the author goes a little way into the ecology of the subject, and states that the Buckthorns grows mostly on the chalk, and would wither away and die if planted by man on damp clay soil. A good gardener, however, would see to the drainage and the Buckthorn would be happy even on clay. A description of the tall Black Poplar shows it to be the Italian Black Poplar. Among the grasses, line drawings of the Meadow Fescue and the Wild Oat (Avena fatua) are true to nature. The Tumid Field Brome Grass might be Bromus secalinus, but is not figured, and could scarcely be B. arvensis, which is one of the least tumid.

We would have described the Daisy differently, for the author states that Bellis perennis means "always pretty," whereas Linnaeus merely meant the Perennial Daisy. If he had taken the name Daisy, he would have found that it came from the Saxon *daegesege*, the day's eye, which opens in the morning and closes at night or late in the day. The ray florets are female, while the disc florets are stated to be male, whereas they are hermaphrodite and ripen seeds abundantly.

He has used a notebook for the past thirty years and chronicled each day's observations, including many red-letter days, but the latter were so vividly impressed upon the memory that written record was unnecessary. That is quite true, but much pleasure can be derived by reading the notes of observations made thirty or forty years ago. He himself writes that, forty years ago he was lifted up to look into a chaffinch's nest in a tangled bush, and the sight of it marked the birth-day of his Nature-lore, his initiation into the life of a naturalist. He has much to say about the chaffinch, and many other of the more common and interesting birds, beasts and insects to be seen in the countryside. The twenty-two line drawings will be helpful to the beginner, and a full index gives the names of everything mentioned in the book, while the type is large, and the contents without technicalities and readable. *J. F.*

RAISING DAFFODILS IN NEW ZEALAND.

This is an ambitious subject for a neophyte to tackle, especially by one whose purse does not allow of the purchase of the more recent and expensive varieties, but the attempt may be justified because, although hundreds of growers are raising seedlings, I see very little written about the matter, and I believe the records of failures are almost as valuable as those of successes; moreover, I have stumbled upon one fact which I have not seen mentioned in any breeding experiments. I would like to stimulate others to record their experiences, so that in course of time complete lists might be made of good and shy seed-bearers, of potent pollen parents and also of the absolute mules; such lists as the late Rev. Joseph Jacob gave in *Daffodils*, of the Present Day Gardening Series.

In a not very extensive garden library, I am fortunate in possessing *The Propagation and Improvement of Flowering Plants*, written by that great gardener, F. W. Burbidge, in 1876. He quotes Dean Herbert's experiments, who found *inter alia* that Narcissus Odorus never seemed to set seeds either in cultivaton or in its native habitats, that the pollen of Soleil d'Or and Double Roman Hermiones (Tazetta) invariably failed, but that of States General pollenated almost every Ajar touched with it.

In my own limited experience I have tried for years to induce Narcissus Odorus to seed, but have always failed; nor have I succeeded in getting seeds from States General, nor my four Poetaz varieties, Elvira, Starlight, Jaune à Merveille and Scarlet Gem. But I have three seedlings of Narcissus triandrus var. calathinus pollenated by Jaune à Merveille. The flower was emasculted, but of the twenty-four seedlings, twenty-one were pure calathinus and the other three showed the cross. The best is Jaune à Merveille, with a fairly wide large cup of the same pure yellow as the perianth. It is very slow of increase and rather a late variety, but very good. One flower out of a truss on a seedling yellow Tazetta, seems to have set seeds with pollen of Soleil d'Or this year.

Another cross I attempted was by using pollen of N. triandrus var. albus on N. Jonquilla; seventy seedlings resulted, of which sixty-nine were N. Jonquilla and one a definite cross. This is a beauty. It is multiplying fairly rapidly, is very free-flowering (commenced in its second year), and is of a lovely luminous citron-yellow with the trumpet somewhat large and paler than the perianth, which is a little reflexed.

Last year I crossed about sixty N. Jonquilla flowers with some dozen varieties of pollen, emasculating every flower as it opened. No seeds set, except with Narcissus triandrus var. calathinus, but the seeds were extremely small and none has germinated. I had a somewhat similar experience with Paper White Narcissi; these seed freely with me, especially when two varieties of it are crossed; last year seedlings flowered contemporaneously with an early white Trumpet, which I believe to be Madame de Graaff, although it never seeds with me; I made many reciprocal crosses, invariably removing the stamens except in one or two flowers; no seeds set on either variety except the two or three Paper Whites which were not emasculated.

These experiences have led me to believe that I have, as I stated, stumbled upon a fact of some importance, viz., that to succeed in a wide cross it is necessary to refrain from emasculating the flowers; the foreign pollen used alone does not stimulate seed production, but if applied at the earliest moment to the stigma to which its own pollen has later access, the latter causes normal seed production and an odd grain of the strange pollen may succeed in reaching an ovule which then is enabled to grow, because of the active metabolism by which it is surrounded. This year, at any rate, I am trying similar crosses with both Paper White and Jonquilla, not emasculated, and hope to be able to record some further successes. I may add that, last year, pollen of Jonquilla produced abundant seeds from Lord Roberts and King Alfred, and this year the Paper Whites (unfortunately much too early for the Trumpets) have set about five hundred seeds without hand pollenation.

If there is anything in the foregoing observation it must apply to many other plants as well, and may help to explain Sir Arthur Hort's success with Iris crosses, for he admits he does not remove anthers; it may also help to explain the difficulty of reproducing Lilium Parkmannii and Lilium testaceum by crossing their reputed parents.

To return to Daffodils, Narcissus triandrus var. calathinus and N. t. var. albus are short- and long-styled respectively, and may by analogy be expected to produce an offspring more vigorous than either parent; the former does badly in most parts of my garden, but one clump is doing very well in a border which is shaded after midday and which has been top-dressed with spent Hops; these same Hops seem to suit most Daffodils very well indeed, but they do not suit N. Bulbocodium var. conspicuus, which is almost a weed in this soil and climate. A neighbour of mine, and a raiser of many magnificent seedlings including peach-coloured Trumpets, uses no other manure than the Hops and gets the best results, but perhaps it is the conjunction with our light volcanic soil which causes the success.

All my earliest crosses were made with pollen of N. triandrus varieties; one considerable success resulted from crossing N. Tazetta with pollen of Snowdrop; the resulting seedlings are wonderfully vigorous, with grand, large heads of very large, well-coloured flowers almost comparable with Poetaz varieties but much earlier. The yellows, as in the majority of N. triandrus seedlings, tend to be light and soft. These seedlings bear seeds freely, and I have seedlings from them from pollen of N. cyclamineus, N. Telamonius, and a very early yellow bicolor Trumpet. N. t. var. calathinus pollen on Trumpets, especially Madame Plemp, has produced flowers close to Bennett Poe, one of them bearing twin flowers with long trumpets, the trumpet colour being paler yellow with an almost white rim; crossed with Dante, it has also produced twins, as has pollen of Bennett Poe itself, but the perianths are narrow and stellate.

N. triandrus var. albus has also crossed with N. minimus, but the results, although interesting, are rather " squinny "; they combine the minimus trumpet with very narrow, reflexed petals.

My poorest results are with N. poeticus seedlings but so far I have done little with Horace and Cassandra.

N. moschatus I have lost, but I have flowered seedlings of it pollenated by Madame de Graaff and N. triandrus var. albus, and also seedlings of Peter Barr, Glory of Noordwijk, and Libra crossed with its pollen. I hope to try crosses between these seedlings to reproduce, if possible, N. moschatus by Mendelian segregation.

N. cyclamineus is doing very well with me and not in the wet conditions advocated by Mr. Peter Barr, although I will certainly try it for them. It has produced seeds with Tazettas and Trumpets, but they are too young yet for me to know their behaviour; the former, especially, are growing vigorously, producing second and third leaves, and I am hopeful they will flower in their second or third year.

I will conclude with one last observation. Firebrand pollen on an Incomparabilis produced normal-sized seeds, which have germinated fairly well, but with Lord Roberts it produced very small seeds, so much so that I thought only five or six were good and labelled the pot with five seeds only, but nine seedlings have appeared! If the resulting flowers exceed expectation as much as their germination has done, I shall count myself very fortunate. *W. M. Thomson, Taranaki, N.Z.*

BULB GARDEN.

TULIPA GREIGII.

This Tulip species is one of the best for the rock garden for those who delight in a sheer blaze of colour. While rather too tall in habit for the small rock garden, it is superb on a sunny ledge in a more imposing structure, its glowing scarlet cups being a most striking sight. Tulipa Greigii (Fig. 153) is also remarkable for its handsome, grey-green leaves which are curiously blotched with brownish-purple markings, and which make a pleasing picture for several weeks before the flowers appear on their twelve-inch stems.

Tulipa Greigii is, perhaps, more insistent than other species on having a thorough baking and drying-off after flowering if the bulbs are to store up enough energy for another display in the following year, so that it is perhaps as well to make sure that wet is not allowed to reach them from after the flowering period until the early spring. This may be effected either by lifting the bulbs when the foliage has died down, and storing them in a cool place until planting time in October or November, or, by covering the bulbs *in situ* with a pane of glass.

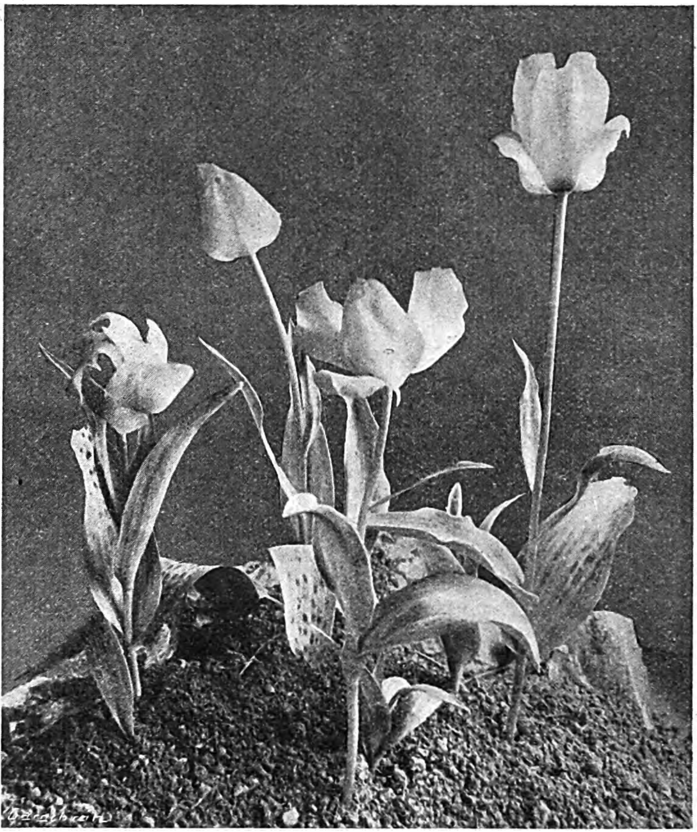

FIG. 153.—TULIPA GREIGII.

Tulipa Greigii may also be grown in pans in the alpine house, where the blossoms may shine undamaged by wind or rain, and where the bulbs may be ripened more easily for another year. In any case, Tulipa Greigii may be replaced each year by imported bulbs if it is found that it will not withstand our summer, and really, the effect in spring makes such an expense well worth while. *Reginald Kaye, The Birch, Sharpthorne, Sussex.*

GALANTHUS NIVALIS VAR. VIRIDAPICE.

One finds that some growers have formed an impression that the form of Galanthus nivalis known as viridapice is identical with G. n. var. virescens, but this is not so. G. n. var. viridapice has not the green inner segments of var. virescens, and the green flushing at the apex of the outer segments of G. n. var. viridapice is fainter and smaller than that on those of var. virescens. I do not know the origin of G. n. var. viridapice, and it was apparently unknown at the time of the Snowdrop Conference of the R.H.S. in 1891, as it is not mentioned in any of the exhaustive papers read then. It would be interesting to know its origin; but it is a much less distinct plant than var. virescens, and I can hardly think that it is a seedling of that form of G. nivalis. *S. Arnott.*

WOODLAND GARDEN.

UVULARIAS.

These herbaceous perennials, mostly natives of North America, are usually among the first to show the fresh green of spring. They are not, as a whole, a particularly ornamental tribe but some of them have their uses, and all posses, a certain elegance of growth which will appeal to those who appreciate foliage plants. For the woodland, for growing between shrubs, or furnishing waste corners and waterside banks, the Uvularias will not be found wanting. They enjoy shady situations and a cool, good soil. With such conditions they will spread into little colonies very much after the manner of Solomon's Seal. Although they do not grow much taller than a foot, they suggest the last-named plant in their pairs of glossy, oval-pointed leaves, the arching grace of their slender stems, and pendulous, bell-shaped flowers.

The best of the genus known to me is U. grandiflora, which bears creamy-yellow blossoms in May. The more leafy, U. perfoliata might be given second place, and there are one or two more, including one from China. All that I have grown are shallow rooters, and as they have no little zest for colonising, they should be given such places as those suggested, rather than the companionship of choicer plants.

The genus Uvularia, of the Natural Order Liliaceae, is closely allied to that of Disporum, and several species at one time known as Uvularia, have now been referred to Disporum. *J.*

FLOWER GARDEN.

NICOTIANAS.

The Tobacco plants form a group of half-hardy annuals of a highly ornamental character, and they are useful for various purposes in the garden. Of a tender nature, it is not safe to plant them out until the end of May or the beginning of June, but they are very quick-growing and not infrequently suffer from being sown too early. The best practice is to sow the seeds in heat about the middle of April, prick the seedlings into boxes so soon as they may be handled, and plant them out from these boxes when conditions allow; such plants will make far better material than earlier-sown ones which have been starved.

The larger-growing species are excellent subjects for sub-tropical beds and groups, their handsome foliage giving them an imposing appearance. The most striking are N. Tabacum, with short racemes of rose-coloured flowers, and N. sylvestris, a highly effective plant of robust stature with long, tubular, pure white, fragrant blooms. N. affinis is a very popular plant because of its delicious fragrance, particularly in early morning and evening; it should be grown in small groups near the dwelling-house windows and by frequented paths. It is also an excellent subject as a pot plant for furnishing the conservatory.

N. Sanderae and its hybrids form a group of highly decorative plants of elegant, branching habit, bearing beautiful flowers on light, graceful stems, and covering a wide range of colours. They are valuable as border plants or for massing in beds, and remain decorative from early July until well into the autumn. *W. A.*

SODIUM CHLORATE AS A WEED-KILLER.

In the issue of *The Gardeners' Chronicle* for February 23, p. 151, it is stated that no reference to the use of sodium chlorate as a weed-killer can be found.

This chemical has been tried out by several State agricultural departments here in America and is highly recommended. Tests conducted recently at Cornell, New York, have proved sodium chlorate to be deadly to Thistles, and in Kansas it was equally successful against Bindweed. At Purdue, Ind., where, I think, it was first tried, experiments were made about 1914 with various chemicals for the purpose of combating weeds possessing deep roots, such as the Thistle, Bindweed and Quack Grass Couch). The substance sought was not for the destruction of weeds on paths, etc., but on agricultural land that had become over-run with the above weeds. No success was attained until sodium chlorate was tried. The first tests killed ninety-five per cent. of the Quack Grass. [See *Gard. Chron.*, March 9, p. 174.—Eds.].

Sodium chlorate is readily dissolved in water at the rate of 1 lb. to a gallon, and it is either sprinkled or sprayed on, the tops of the weeds being thoroughly saturated. The best time to do this work is when the plants start to bloom.

Sodium chlorate is made only by one concern in this country, at Niagara Falls, the cost being about 30s. per 112 lb. drum. One drum is sufficient to spray an acre. The chemical is not poisonous to livestock, and it does not harm the soil. The action of this sodium on plant growth is to oxidise the tissues. There is one danger only in its use; if mixed with small particles of organic matter it becomes combustible, therefore it should not be handled indoors, and all clothing and shoes worn while applying the spray should be washed before they are allowed to dry, as even friction may cause fire.

Sodium arsenite is also used for a similar purpose, but this is deadly poison, and, if used heavily, it will prevent all forms of plant life growing for months, or even years. It is not so penetrating, however, on deep rooting weeds as sodium chlorate, but is to be recommended for walks, hard tennis courts, etc., because of its sterilising character on the soil. *T. A. Weston, New Jersey, U.S.A.*

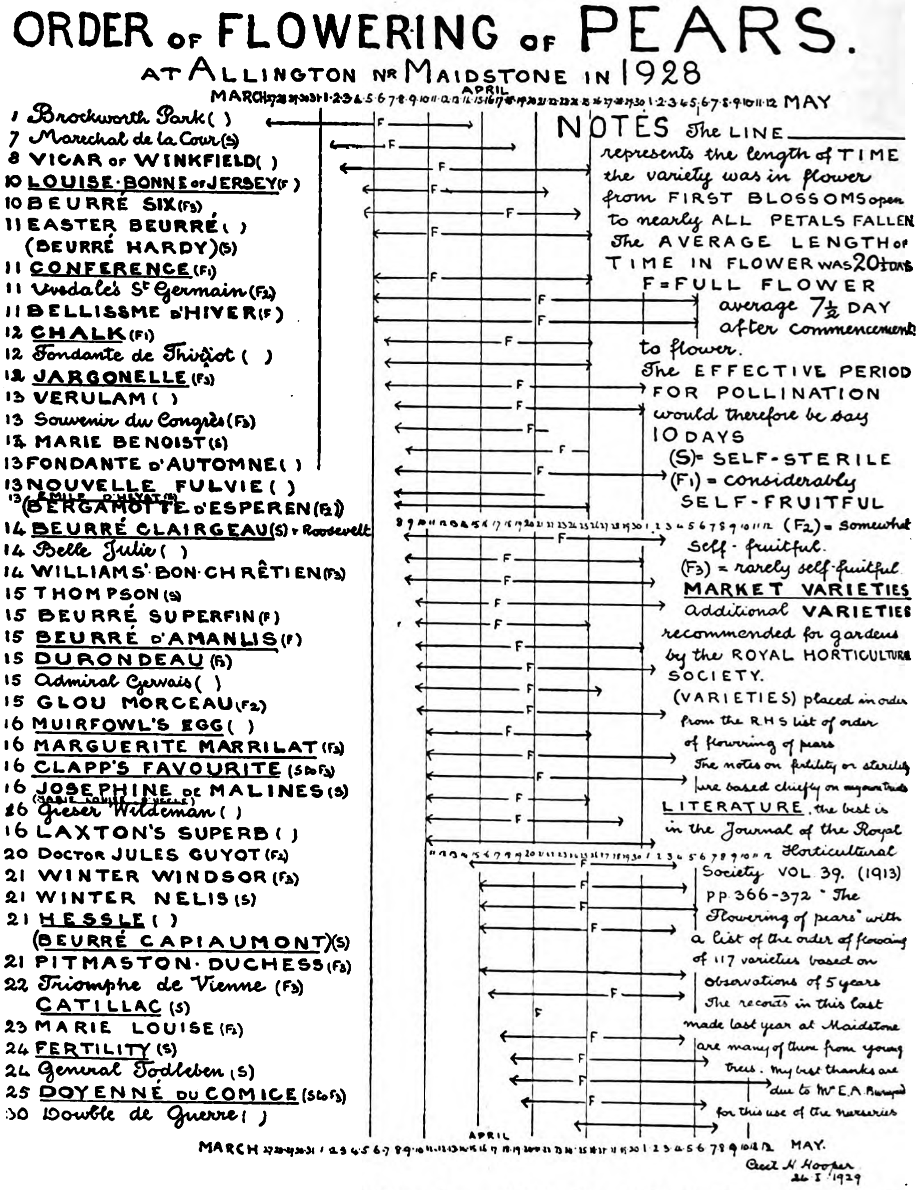
ORDER OF FLOWERING AND POLLENATION OF FRUIT BLOSSOMS.*

(Continued from p. 282).

Pears.

Pears are of special interest in the history of research in fruit pollenation, as it was in 1890 that M. B. Waite was asked by the Department of Agriculture of the U.S.A. to investigate the cause of unfruitfulness of an orchard of 22,000 Williams's Bon Chrétien trees which, although planted fifteen years and healthy, hardly yielded any fruit. In this orchard it happened that three trees of different varieties had been planted by mistake among the Williams' (two Clapp's Favourite and one Buffam). In the neighbourhood of these three trees the Williams' were very productive, bearing down the branches to the ground with the weight of the fruit. His previous experiments led Mr. Waite to believe that this limited and local abundance was caused by cross-fertilisation from the other trees, and this view was fully confirmed by all his subsequent experiments. I had an example of the importance of pollenation in Pears, although on a small scale, when fruit-farming at Swanley, Kent; I planted forty-eight Pitmaston Duchess pyramid trees in an Apple orchard on flat, rather low land; although for four years they flowered well, they did not mature a single fruit. I therefore had them taken up and replanted them on a hill-side about a quarter-of-a-mile away in a plantation of Pears of different sorts and placed a hive of bees among them; the trees then bore well.

In my own experiments I have found the following varieties more or less self-fruitful:—Conference, Dr. Jules Guyot, Chalk, Beurré d'Amanlis, Swan's Egg, Colmar d'Eté, Duchesse d'Angoulème, Marguerite Marillat, Winter Windsor, Jargonelle, Souvenir du Congrès, Beurré Diel, Durondeau, Petite Marguerite, Blickling and Glou Morceau. Only one fruit from each has matured with me out of many trials with Pitmaston, Williams' Bon Chrêtien and Doyenné du Comice. No fruit matured in my trials with own pollen from Clapp's Favourite, Fertility, Emile d'Heyst or Catillac.



At the Royal Horticultural Society's Gardens at Wisley, Mr. F. J. Chittenden and Mr. A. N. Rawes have experimented to a considerable extent on the pollenation of Pears, as well as of Apples and Plums; in a recent letter, Mr. Chittenden gave me the names of fifty-two varieties that had been found to be self-fertile to a greater or lesser extent under glass, and of forty-four that had not, so far, matured fruit with pollen of the same variety.

In Pears, some of the best varieties are shy bearers. Last year I tried twenty-six different kinds of pollen with Doyenné du Comice, but only from six of these did fruit mature; these were from the pollen of Hessle, Triomphe de Vienne, Fertility, Grégoire Bordillon and Madame Lye Baltet; but another year many of the other varieties which failed might mature good fruit.

Careful observations in successful and unsuccessful Pear plantations might yield many facts and suggestions which might be checked by pollination trials.

---

* A paper read before the Royal Society of Arts, Wednesday, February 13, by Mr. Cecil H. Hooper, F.L.S., of Wye, Kent.; Mr. H. V. Taylor, O.B.E., Commissioner for Horticulture, Ministry of Agriculture, presided.

Among successful pollenation results were :—Clapp's Favourite with Conference; Dr. Jules Guyot with Clapp's Favourite, or Roosevelt; Fertility with Conference; Durondeau with Fertility; General Todleben with Conference; Vicar of Winkfield with Winter Cresanne; Williams's Bon Chrétien with Clapp's Favourite, Winter Cresanne or Fertility; Pitmaston with Conference or Williams's Bon Chrétien; Uvedale's St. Germain with Marie Louise; Catillac with Fertility or Uvedale's St. Germain.

Apples.

Although a considerable proportion of Apples are gradually being shown to be more or less self-fruitful (under glass varying from seven per cent. down to 0·2 per cent.), yet all experimenters agree that no single variety can be advantageously planted alone and that all varieties yield more if interplanted with one or more varieties in flower at the same time. Even the most self-fruitful variety will yield three or four times the crop in association with other varieties, than if planted alone.

In 1910, I placed three paper bags over unopened blossoms on trees of sixty-three different varieties of Apple, with the following results :—1, with insects excluded only Irish Peach matured fruit; 2, flowers pollenated with own pollen, eleven varieties matured fruit; and 3, flowers pollenated with a different pollen, forty-eight varieties matured fruit. These were single trials in each case, but my experience since is that this gives a fairly correct idea of Apple pollenation in the open air. Among the varieties found most self-fruitful are :—Stirling Castle, Rev. W. Wilks, Golden Spire, Irish Peach, Christmas Pearmain, Baumann's Red Winter Reinette, Ben's Red, Miller's Seedling, Lord Derby, White Transparent and Tower of Glamis, but after many trials I have never persuaded Cox's Orange Pippin or Lane's Prince Albert to mature fruit with their own pollen.

Where a variety has been planted alone in a block, it is recommended to re-graft or replace one tree in eight with a different variety flowering about the same time; Bramley's Seedling is found to be a specially good variety with which to re-graft. Each third tree in each row of a different variety is considered the minimum proportion for a pollenising variety.

In planting a new orchard it is advisable to plant not more than two or three rows of one variety and then alternate with another variety (see table below for times of flowering).

Experience and experiment show the following to be good varieties to plant together, although other combinations may succeed equally well :—Cox's Orange Pippin with Worcester Pearmain; Bramley's Seedling with Lane's Prince Albert; Newton Wonder with Lord Derby; Blenheim Pippin with Newton Wonder; Early Victoria with Grenadier; Beauty of Bath with Allington Pippin; James Grieve and Cox's Orange Pippin; and Gladstone with Cox's Orange Pippin or Worcester Pearmain. In many trials I have found Cox's Orange Pippin to be a good polleniser, the crosses have almost always taken and matured fruit. R. Florin, in Sweden, found the pollen germination of Cox's Orange Pippin to be ninety-eight per cent.

(*To be continued*).

HOME CORRESPONDENCE.

Oil Fuel for Boilers.—The article on "Stoking" by Mr. A. S. Turner, on p. 188, is appropriate, and very much to the point, after such a spell of arctic weather as we have had recently. Stoking in gardens is very often left to boys, or an odd man, with the result that when heat is most needed on a frosty night the fire is low, then, when the sun is shining during the day there is generally a brilliant fire! On taking charge here, I was told the boilers were not doing their work, and on examination, I found the flues choked with soot, and all the air spaces between the fire bars full of clinkers. The method of getting rid of ashes and clinkers had been to throw them back in a heap behind the boilers instead of clearing them out of the stokehole, and during wet weather when water percolated through the walls one can imagine what condition the boilers would be in surrounded by a heap of wet ashes. We have now had Ray oil burners installed, which burn crude oil, and I can recommend them as far more efficient than the old method of stoking with either coal or coke. Once started, the heat rises to whatever temperature the aerostat is set at, when the burner automatically stops, but when the temperature falls about 5°, the heat starts again, and so the temperature in the house remains fairly constant. The burners are run by electricity, off the main, and the current also lights a gas jet, which in turn lights the oil; when the oil is well alight the gas is automatically cut off. There is a flow and return pipe from the burner to the oil tank, and when the burner stops the oil returns to the tank. We have also a circulating pump attached to the pipes which is a great improvement, and a sump in the floor for soakage water, which is automatically pumped out so soon as the hole is full. All pumps and burners are run by current from the main, and if it is necessary to stop one, all that is needed is to pull down a switch. I do not know yet whether this method is more economical than coal or coke, but it is no trouble, and there is no dirt. The stokeholes are all whitewashed, water pipes painted with aluminium paint, gas and oil pipes red, electricity black, and the floors washed out, which is something quite different to the old method of dust and dirt. I shall be pleased to give any of your readers further particulars if they desire it. *Grigor Roy, The Gardens, Bevendean, Oxshott.*

Frost Injury to Fruit Trees.—With reference to the article under the above heading in your issue of March 16 (p. 209), I may state that while I see no injury from the severe frosts of this winter, last winter's frost did damage to a considerable extent. The only variety of Apple affected was Lord Derby, and the damage done was to the young wood. Current growth was killed and second- and even third-year wood died back. The same may be stated of many spurs. After the pruning was completed, the trees presented a sorry sight, and the heads of the trees were reduced by about one-half. Every Lord Derby on my place was affected, and on a neighbouring farm even more extensive damage was done. These trees developed canker and look complete wrecks, although they are young and were a fine, promising lot. The owner now considers them injured beyond hope, and intends heading them back and regrafting. During the same winter all the Conference Pear grafts I had put in during that year were killed. This winter has not damaged Lord Derby Apple, nor has it injured Conference Pear grafts. This fact appears remarkable, as we had lower temperatures this year, over a longer period, but it is the case that less damage is evident in the garden generally this year. Ivy, Privet and rambler Roses are a few plants which show no signs of injury, but which suffered terribly last year. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

Arenaria norvegica. — In *The Gardeners' Chronicle* of April 7, 1928, the writer of an article on this plant referred to it having been reported from North Ronaldshay, in the Orkneys, by Sir R. Murchison and Mr. Reach (perhaps Mr. Peach, the geologist, was meant). Can he confirm that record, which is not usually credited? I may add that it does occur in several localities in west Sutherland. Confirming the occurrence of Geranium lancastriense on the mainland, may I state that about five years ago, Mr. R. H. Williamson and I found several plants of it near Seascale. *Claridge Druce.*

MARKET FRUIT GARDEN.

In the first three months of this year the rainfall at my place (2·20 inches) was less than one-third of the average. March contributed very little towards it, for rain fell on only two days during the month, and then the total amount was only ·06. Up to a point, this extraordinary drought has been helpful. The prolonged period of frost finished with that rarity, a dry thaw. As a result of this, the land was left in wonderful condition for cultivation. It might almost be stated that the first cultivation had been done for us. Once through the plantations with either a horse-drawn or motor cultivator produced a tilth such as we often have to work for weeks to obtain. Hand-hoeing in the rows of bush fruits, which is generally very hard work the first time over, was mere child's-play. The whole area was finished without the slightest interruption from rain, and there has been no need to touch the ground since. Instead of the struggle to get through essential work, which is usual at this season, it has actually been necessary to find such make-shift work as ditching to occupy some of the men. Now, however, the drought has gone on too long. Fruit trees and bushes have at last awakened to active growth, and they want moisture. So far they have not been harmed, but they are coming to the time when they make a big demand on the moisture in the soil, and they are bound to suffer if they cannot find enough.

DRY GRASS ORCHARDS.

Most of all, I want rain for my grassed orchards. I am particularly anxious to get more vigour into many of the trees, and applied chemical fertilisers in generous amounts in good time, in the hope that they would get washed into the ground and ready for use at flowering time. Instead of this, they lay for weeks dust dry on the surface. The rough grass, scorched by tar distillate wash and by the artificials, and further affected by the frost and drought, has been entirely brown, and even now, when a few green blades are pushing through, brown is still the prevailing colour. It would have been easy to burn the grass off; and I should have done this if the manures had not been lying on the surface. Two wide strips across one plantation did get burnt by accident, and much activity was needed to check the fire. The effect was very pleasing, particularly after the harrows had been run over the surface. On this burnt area the young grass is springing up thickly. I should say that burning off is quite a sound practice; and I should not hesitate to do it another time, provided that it did not involve the burning of an expensive dressing of artificials, with the possibility of loss of valuable ingredients.

There is a mulch of dry grass in some of my orchards, and I am trying various ways of inducing it to rot. The dry weather has been all against this. Even last year's fallen leaves are still whole. It is curious that in some of the orchards the grass mulch, the result of annual mowing, disappears rapidly, while in others it accumulates. In the former case the trees do well; in the latter they lack vigour. Evidently some means must be found of getting rid of the mulch, which seems to prevent manures from acting on the trees; and I believe I am near a solution of the problem. In the absence of rain, however, nothing can be done.

PREPARATIONS FOR SPRAYING.

Apples are approaching the stage at which spraying against scab must begin—when the buds are showing pink, but before the petals actually open. As all the trees have been sprayed with tar distillate, I do not have to worry about aphides and Apple suckers; so the field is clear for that most important business, the control of scab. On this, more than on anything else, depends the value of a crop of Apples. Fortunately, I am in no doubt as to what method to adopt, having had an excellent control of the disease in the past two years. If the weather allows one to spray at the right times, there is not much difficulty in getting a good proportion of clean fruits. At the pink bud stage, home-made Bordeaux mixture is used. Many growers employ lime-sulphur at this stage with success; but, after comparing the two washes on several occasions, I am satisfied that Bordeaux mixture is decidedly the better in my conditions. This year the making of this wash will be simplified by the use of hydrate of lime in place of quicklime, thus obviating the troublesome business of slaking the lime. The hydrate is bought in paper-lined bags, in which it keeps for a considerable time. The lime has simply to be thinned down with water; but it is necessary to use 1½ lb. in place of each 1 lb. of quicklime. My formula is 6 lb. of copper sulphate and 12 lb. of hydrate of lime to one hundred gallons of water; but the lime will be increased to 30 lb. for Cox's Orange Pippin and Beauty of Bath, which are very tender. After flowering, most varieties are sprayed twice, once just as the last of the petals are falling, and again about three weeks later. Bordeaux mixture is still the better fungicide, as numerous experiments have shown; but, unfortunately, one has to consider very carefully the risk of spray injury, which is much greater after blossoming than it is before. Bordeaux mixture, even the excess of lime formula, is, in my opinion, far too dangerous to apply at this time, if only because it russets the fruits seriously. I use lime-sulphur at very mild strength, one part in eighty for most varieties, one part in one hundred for Cox's Orange Pippin and Beauty of Bath. Lane's Prince Albert, which scabs very little with me, is not sprayed at all after flowering, as it is very sensitive to sulphur washes. Stirling Castle is the same, but I do not grow this. Arsenate of lead is added to the lime-sulphur for the first after-blossoming application, partly to kill any caterpillars that have survived the winter spraying, and partly to increase the fungicidal value of the very mild lime-sulphur. I cannot guarantee that even this programme is absolutely safe, unless one can always apply the lime-sulphur in cloudy weather or in the evening, which is impossible on a large scale. Apparently one must risk doing a little harm in order to do a lot of good.

BLOSSOM PROSPECTS.

While it is much too early to write anything about fruit prospects, it is evident that there will be no lack of bloom on Apples of nearly all varieties. Plums, I fancy, will be more moderate, although the buds are not so easily seen at present in this case. Pears are patchy, but Cob-Nuts bloomed very freely. Black Currants, which made splendid growth last year, look very promising. Everything now depends on the weather at blossoming time. As the blossom will be very late, there should be a good chance of it escaping frost. There was, of course, no March blossoming of Plums. It seems likely that April will be far advanced before they open their petals. *Market Grower.*

SOCIETIES.

LONDON DAFFODIL SHOW.

APRIL 16 AND 17.—The postponed London Daffodil Show, which was held in the old R.H.S. Hall, Westminster, on these dates, compared very favourably with its predecessors in quality, but there were many empty places on the tabling reserved for the competitive classes. As many of these unfilled spaces were in full view from the entrance, the first impression was that of a poor show, which was far from being the case. The many trade groups contained a large number of splendid varieties, and were highly decorative. There were rather fewer novelties than usual at this show, and of these four were selected for Awards of Merit and one for Trial at Wisley.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mr. G. W. Leak, Mr. G. Monro, Mr. P. D. Williams, Mr. J. D. Pearson, Mr. W. B. Cranfield, Mr. Francis Barchard, Mr. H. G. Hawker, Mr. C. H. Curtis, Mrs. Brodie of Brodie, Mr L. J. Richardson, Miss Ellen Willmott, Mr. C. C. Titchmarsh, Mr. F. H. Chapman, Mr. H. Smith, Mr. F. A. Secrett, Mr. W. Slinger, Mr. George Churcher, Mr. Peter R. Barr, Mr. C. W. Needham, Mr. W. F. M. Copeland, Mr. W. Poupart, Rev. Rollo Meyer, Rev. G. H. Engleheart, Mr. J. S. Arkwright, Mr. Guy L. Wilson, and Mr. A. Simmonds, Secretary.

AWARDS OF MERIT.

Narcissus Beersheba.—This lovely, pale cream-coloured Trumpet Daffodil, which stands alone and supreme in its class, was given this award as a variety suitable for cutting. It received a First Class Certificate on March 23, 1926, when exhibited as a show flower. Shown by G. L. WILSON, Esq., Broughshane, Antrim.

N. May Molony.—A beautiful Leedsii hybrid of clear colouring and refined appearance. It has large, spreading, pale cream perianth segments, and a rather long, powdered cup of rich primrose-yellow, crinkled and slightly reflexed at the margin. The foliage is large and deep green, and the blooms are borne on firm, stout stems. Also shown by G. L. WILSON, Esq

N. Solleret.—A grand Jonquilla hybrid of large size and firm texture. The slightly waved and ribbed perianth segments are rich yellow, while the tubular cup is deep golden in colour. A beautiful Narcissus. Exhibited by W. B. CRANFIELD, Esq., East Lodge, Enfield Chase, Middlesex.

N. Adventure.—This striking Narcissus, which was shown as an Incomparabilis, but approaches very closely to a Trumpet Daffodil, is of huge dimensions, with large, broad, rich yellow perianth segments, and a spreading trumpet of rich golden colouring, waved and curled, and reflexed at the mouth. The grand blooms are held well on long, stout stems, and the foliage is rich, deep green and ample. Shown by HERBERT CHAPMAN, Esq., Rye, Sussex.

The above are the only novelties which received awards, but Narcissus Edgar Thurston was recommended by the Committee for Trial at Wisley. This is a golden Trumpet Daffodil, with very curled perianth segments and a large trumpet, reflexed, deeply cut and curled at the margin. It was exhibited by F. A. SECRETT. Esq.

COMPETITIVE CLASSES.

In the open section, the only exhibit of twelve varieties, selected from at least four divisions, was a particularly good one from Mr. J. L. RICHARDSON, and it deservedly received the first prize. The dominant varieties were Folly, Princess Miriam, Tenedos and Royalist. There were two exhibitors in the class for twelve Trumpet varieties, and here Mr. RICHARDSON was first with another very good exhibit, which included Master Robert and Alchemist, rich yellows; Kantara and Beersheba, whites; and a bicolor seedling. Mr. G. L. WILSON was second, and he had fine vases of His Excellency and King of the North, both rich yellow.

Mr. RICHARDSON was also first with twelve Incomparabilis, and he included in Festive, Morea, Killigrew and Grackle, four varieties which have beautifully coloured coronas. Mr. Wilson was again second. Mr. Richardson was the only exhibitor of nine Barrii varieties, and he staged Morocco, Danger and Firetail, with vividly-coloured coronas. There was no exhibit of twelve Leedsii varieties in this section, but Mr. Richardson and Mr. F. A. Secrett staged collections of twelve Poeticus varieties which must have caused the judges considerable anxiety. The prizes were awarded in the order named, and the former included beautiful blooms of Thetis, Dactyl and Ringdove, while the latter had equally good specimens of Red Rim, Standfast and Kathleen.

The following classes required six varieties of each of the different sections. Mr. G. L. Wilson was first with (a) Giant Leedsii; (b) white Trumpet; (c) bicolor Trumpet; (d) Incomparabilis, with red colouring, and (e) without red colouring. His best varieties were (a) Suda, which has a long and beautifully tinted corona; (b) Kantara, (c) Rosemorran, (d) Copper Bowl and (e) Damson. With a very even collection which included Master Robert and Alchemist, Mr. Richardson was first with yellow Trumpets, and although alone in the classes for both types of Barrii varieties, was awarded the first prizes for very good blooms. Mr. A. J. Bliss, Tavistock, the only exhibitor, was awarded second prize for Triandrus varieties; and Mr. W. F. M. Copeland was first for double sorts.

Three varieties were required for each of the following classes. Mr. W. B. Cranfield, the only exhibitor, was awarded the first prize for Jonquilla hybrids of beautiful colouring; and the Rev. G. Pearce, Wadebridge, Cornwall, was placed first with Tazetta hybrids. In the class for Poeticus varieties there were five exhibits, and the first prize was awarded to Mr. R. F. Calvert; Mr. Richardson was first with double sorts.

The twenty classes for single blooms of the various sections were very popular, although while the best blooms were usually very good indeed, there was more than a sprinkling of mediocre examples. Mr. Richardson won first prizes with Royalist, yellow Trumpet; Beersheba, white Trumpet; Gregalach, bicolor Trumpet; Damson, yellow Incomparabilis; St. Egwin, bicolor Barrii; Tenedos, giant Leedsii; Venetia, cup-shaped; triandrus, and Golden Goblet, Jonquilla hybrid. A yellow seedling with a widely expanded, recurved corona, and shown by Mr. E. A. C. Thurston, Chandlers, Ford, was the best Incomparabilis without red colouring; and a seedling shown by the Rev. G. Pearce was the best variety with red colouring. Folly, shown by Mr. Calvert, was the best bicolor Barrii, and Kilter, shown by Captain H. G. Hawker, was the best Barrii with red colouring. Coverack Gem, shown by Mr. Calvert, was the best bicolor Barrii with red colouring, and the same exhibitor was first with Silver Salver, a small Leedsii. Mr. Cranfield showed, in Harvest Moon, the best trumpet-shaped, large Triandrus hybrids, and Goodwin, staged by Miss A. R. Baring, was the best Cyclamineus hybrid. With a good seedling, the Rev. G. Pearce was first for a Tazetta hybrid. Dactyl, shown by Captain Hawker, was the best Poeticus variety, and Inglescombe, exhibited by Mr. R. Harris, was first in the class for doubles.

The classes for new varieties were very interesting and contained many especially good blooms. Mr. G. L. Wilson was first with twelve varieties raised by himself, and these included New Moon and several particularly good seedlings. Mr. Richardson was second. In the class for six varieties, the Rev. Rollo Meyer (gr. Mr. J. P. Izzard), Watton Rectory, Hertford, won the first prize with a collection which included some very good seedlings, and the Rev. G. Pearce was first with three noteworthy seedlings.

Although the only exhibitor of twelve varieties not in commerce, Mr. Richardson was deservedly awarded the first prize. His splendid exhibit included Mithian, Brighter London, Jungle Fire, Sunny Trace and Red Planet, which have very vividly coloured coronas. Including a vase of Princess Badura, a vivid Barrii, and a rich yellow seedling Trumpet, the Rev. T. Buncombe, Black Torrington, Devon, was first with six varieties. In his first prize exhibit of three varieties, Mr. Calvert included a fine vase of Coverack Gem and Money, a rich yellow Trumpet.

The competition in the two classes for groups of Daffodils was very disappointing, and in neither the open nor the amateur class did the first prize appear to have been awarded.

Although there were not many competitors, the exhibits reached a high standard of excellence and well illustrated the quality of the best market produce, as well as the skill exercised in bunching and packing. Mr. F. A. Secrett won first prizes with nine superb bunches of yellow Trumpet varieties, and with a similar number of equally admirable Poeticus varieties, and an ideal box of Red Rim. Mr. H. W. White was first with boxes of Tresserve, and of Bath's Flame of equally high merit.

Groups.

The arrangement of the large trade groups at this show could have been improved greatly, for, with the exception of those lining the walls, they were bundled together at one end of the hall, leaving the other end comparatively bare.

Situated on the right-hand side of the entrance was a grand display of Poeticus Narcissi by Mr. F. A. Secrett, of light and charming arrangement, and consisting of blooms of excellent quality. There were huge sheaves of Red Rim, a beautiful sort with reflexed and waved, pure white perianth segments of good substance, and a bright, richly coloured crown—this variety occupied pride of place; other sorts displayed extensively being Narrabri, Charity, of charming form and good substance; Winnie Weedon, and Wide Wing. At the front of this exhibit were charming bowls of Much-Afraid, Papyrus, Kathleen and Peace.

On the other side of the entrance was a grand bank of choice blooms set up by Messrs. Barr and Sons. Trumpet and Incomparabilis sorts were most prominent, of the former, noteworthy sorts being Polemon, King Alfred, Tresserve, Glory of Sassenheim, and St. Hilda. There were several good seedling Daffodils exhibited in this group, while among Incomparabilis and other varieties which made special appeal were Hera, Sweet Rosalind, Sunrise, Snowbird, Fortune's Queen, Mitylene and Abelard.

A really grand display of blooms, of perfect quality, was staged by Mr. R. F. Calvert. At intervals along the group were sheaves of such sorts as Firetail, Dragoon, the double-flowered Cheerfulness, Croesus, the giant J. K. Ramsbottom, and Ideal; while dotted throughout the display were such beautiful sorts as Lucinius; the large, golden, Trumpet variety Herbert Smith; Gaza, Amir, Prince Fushimi, Mitylene, Penzance, Nanny Nun, Darius, White Sentinel, Ettrick, White Conqueror and Irma, these being outstanding, although all were extremely beautiful.

Large, golden Trumpet sorts were shown chiefly by the Welsh Bulb Fields Co., and these were in splendid condition, and included such grand sorts as Remus, Rugby, Bimbo, Nugget, Romulus and Canute; other good Trumpet varieties, of paler colouring, were Alba, May, Tantalus, Melyn, Bronwen and Phyllis Vansittart.

Messrs. Sutton and Sons Ltd. had a tastefully arranged group consisting chiefly of Trumpet Daffodils, many of which were seedlings and, unfortunately, at present unnamed. The blooms were in grand condition and were arranged in decorative baskets in association with Asparagus sprays. Among good named sorts in this group were Midas, a dainty Poeticus variety; Golden Pedestal, Tunis, Treskerby, Cicely, and Nissa.

Another grand display was staged by The Donard Nursery Co., the blooms being in splendid condition. There were fine examples of Brightling, Royal Lancer, Copperbowl, Beauty of Radnor, Croesus, Redlight, Gallipoli and Mitylene, among Incomparabilis sorts, while noteworthy Trumpet varieties were Rosemorran Giant, Tace, Gog, Herbert Smith, Magog, Grenade, Eskimo, Beersheba, White Nile, Kantara, Tenedos and Everest.

Messrs. J. W. Barr staged a small group of numerous sorts, but it was far from decoratively arranged, and the red tag-labels detracted considerably from any attractions the display might have possessed. Messrs. Tyler Bros. staged vases of the rich golden Trumpet variety Grand Master, while among good sorts displayed by Messrs. R. H. Bath, Ltd., were Advance Guard, Golden Sunset, Aerolite, The Don, The Marquis and Golden Sunrise, all Trumpet varieties; several double-flowered sorts, and Brilliancy and Gaiety.

A really grand and very extensive display of splendid blooms was set up by Mr. J. L. Richardson. Trumpet varieties were represented by Golden Goblet, Master Robert, Tipperary Lad, Royalist, Alchemist and Hebron—golden sorts—and White Emperor, Kantara, Helen O'Hara, Halfa, Beersheba (very fine), Tenedos, Marquis of Headfort and Eskimo—cream-coloured varieties. There were grand blooms of such choice Incomparabilis varieties as Brightling, Gallipoli, Folly, Silver Plane, Mitylene, Festive, Hades, White Sentinel, Hymethus and Hera; while outstanding Poeticus varieties were Princess Miriam, Inca, Firetail, Mystic, Sunstar, Minuet, The Sahib, Marco, Dactyl and Matthew Arnold.

Grand blooms of many choice Narcissus novelties were displayed by Mr. G. L. Wilson. He had splendid examples of Beersheba, Lord Antrim, Honey Boy, Tenedos, White Nile, Sorley Boy, Bulwark, Marmora, the delicately-shaded Suda, Nevis, Eskimo and Quartz, together with several good seedlings, among Trumpet varieties; also several very lovely Incomparabilis varieties and, among Poeticus Narcissi, the dainty Mystic, Glorious, New Moon, Fairy Circle and Medusa.

A superb collection of new varieties and wonderful seedlings (under number) was arranged in one corner of the hall, but alas! there was no card to identify the exhibit with any person. The exhibitor, however, was Mr. P. D. Williams, of Lanarth, Cornwall. His varieties Porthilly, Grayling, Crocus, Scarlet Lancer and the deep orange-gold No. 215, were magnificent, while numerous Poeticus, and white Bairii sorts, were scarcely less beautiful.

Messrs. John Wilson, Ltd., had good blooms of Tresserve, Croesus, Mrs. R. O. Backhouse, Mitylene and Red Cross; while Messrs. D. Stewart and Son made special features of Macebearer, Lord Kitchener, Brilliancy, Primrose Phoenix, Mermaid, Tony, a giant Leedsii of charm; Bernardino, Van Waveren's Giant, Sunrise and Buttercup. They also had several miniature Narcissi, including N. Jonquilla, N. triandrus var. calathinus, N. juncifolius, and N. Bulbocodium in several varieties.

Mr. Herbert G. Longford staged, in large sheaves, good blooms of several choice Poeticus and Trumpet varieties.

Messrs. Barford and Perkins, Ltd., displayed one of their bulb sterilising plants, capable of "cooking" 3 cwts. of bulbs at a time—a type popular among commercial bulb-growers in this country.

THE ORCHID CLUB.

At the meeting of the Orchid Club, held on April 12, there was a choice but not large collection of exhibits. Dendrobiums and Odontiodas were the predominating feature.

Premier Diploma.

Dendrobium Renown var. Carmen.—This fine variety received the Club's lower award on April 20, 1928, but the Committee considered that the improvement shown in the breadth and colour of the segments justified the bestowal of the higher award. Exhibited by F. T. Paul, Esq.

New Hybrid.

Cypripedium bellbeechense (*C. bellatulum* × *C. beechense*).— Submitted for registration by F. T Paul, Esq.,

Groups.

Dr. F. Craven Moore (gr. Mr. Gilden) exhibited a select group of magnificently grown and flowered Dendrobiums and Odontiodas. Among the former were several plants of D. Thwaitesiae, Veitch's var., D. Wardianum and

D.Sybil var. superbum. The Odontiodas included O. Cora with a branched spike of thirty-four large flowers; O. Gladys var. superba, a fine variety carrying fifty-five brightly-marbled blooms; O. Marathon, with twelve huge flowers, and several others. The centre of this fine group was occupied by beautiful plants of Selenipedium macrochilum, while Eulophia Saundersiana, with its curious flowers smelling like freshly caught trout, was also noted.

A. T. Cussons, Esq. (gr. Mr. Dalgleish), showed a mixed group which included several plants of the pretty Odontioda heatonensis, O. Brilliant, with a good branched spike; various Dendrobiums, and a few late Cypripediums.

F. T. Paul, Esq., F.R.C.S., staged a few select Dendrobiums including a promising seedling between D. Sir F. Moore and D. Cybele; the fine D. Renown var. Carmen and an interesting new Cypripedium hybrid, raised at Cloudeslee, between C. bellatulum and C. beechense.

B. J. Beckton, Esq. (gr. Mr. W. A. Stewart) exhibited well-flowered plants of Odontoglossum Oerstedii and Pleurothallis astriophora, together with a series of photographs of Orchid species, taken by himself, being additions to the series shown last session. Several species were photographed in duplicate, showing firstly the habit of the plant, and secondly, the flower exactly life size. Among the species illustrated the following stood out as distinct examples of the wonderful modifications of structure which are found in the Order Orchidaceae. Catasetum Darwinianum, C. Bungerothii, C. Oerstedii and C. fimbriatum; Stanhopea occulata and S. ecornuta; Mormodes pardinum, Haemaria discolor, Neomoorea irrorata, Maxillaria Fletcheriana, Cirrhopetalum longissimum, Cypripedium Lowii and Bulbophyllum saltatorium. Coryanthes macrantha was represented by a series of five photographs showing the development of the bloom from the early bud stage to the fully developed blossom, and one full-size showing the curious provision the plant makes for effective fertilisation. A vote of thanks was passed for this exhibit.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall, on Monday, April 8, Mr. T. R. Butler presiding. Two new members were elected. Five members withdrew £21 15s. 4d., *i.e.*, double the amount of the interest on their deposit accounts; and five members over the age of seventy years withdrew £251 12s. 0d. from their deposit accounts. The sum of £209 12s. 3d. was passed for payment to the nominees of five deceased members. The sick-pay for the month on the Ordinary side amounted to £242 7s. 4d., and on the State side to £203 14s. 10d.; maternity claims came to £4 10s. 0d. Grants amounting to £48 19s. 0d. were made to fourteen members towards optical and dental treatment, and several other cases were considered.

READING GARDENERS'.

The final fortnightly meeting of this Association for the spring session was held in the Abbey Hall, on April 8, the President, Frank Moring, Esq., presiding over a really good attendance of members.

In Class 1, for the best floral decoration of a dinner table six feet by four feet, the first prize was awarded to Mr. H. R. Tuffin, The Gardens, Iris Court, Pangbourne (Pink Carnations); second, Mr. R. H. S. Dann, The Gardens, Greenlands, Henley-on-Thames (Carnations and Primula malacoides); and third, Mr. A. W. Gower, The Gardens, Calcot Grange (a deep-coloured P. malacoides).

In Class 2 (for under-gardeners only), for a vase of Daffodils arranged for effect, Mr. R. H. S. Dann was first, and Mr. R. H. Goodchild, The Gardens, Cliffe House, Mapledurham, second.

It being "hospital night," a collection of cut flowers was sent to the Royal Berkshire Hospital after the meeting; it included Carnations, Primula malacoides, Cinerarias and Daffodils, and these were contributed by Messrs. Broomfield, Dow, C. Cook, Fulker, Gower, Moulton, Plumridge, Townsend, Tuffin, Turnham and J. Wynn. A collection taken in the room towards the funds of the institution enabled the Association to send a donation of £3 10s. 0d.

The lecture for the evening was on "Gladioli," by Mr. T. C. Waite, of the Hardy Plant Nurseries, Basingstoke Road, Reading. He stated that Gladioli have been grown in English gardens for at least five hundred years. He described the various species that had been introduced, and gave details of the preparation of the soil (deep digging being essential), planting the corms, fertilisers, watering, mulching, cutting the flower spikes, and lifting and storing the corms. Then followed useful suggestions as to raising plants from seeds, and, in conclusion, the best varieties in the various colours were given. There was only time for a short discussion, at the close of which a hearty vote of thanks was accorded Mr. Waite for his practical and interesting lecture.

Obituary.

Joseph May.—We regret to learn of the death of Mr. Joseph May, who passed away on Wednesday, April 10, after a very short illness, at the age of eighty-one. He was for many years well-known as gardener at Northaw House, Potters Bar, and an account of his career appeared in these columns on October 8, 1927. He retired about seven years ago, and by the kindness of Mr. J. B. Joel was able to spend his remaining years with his son, at the Gardens, Childwick Bury, where, until a few days before his death, he took a keen interest in everything pertaining to the garden. Always keen on hardy fruits, the sight of a well-trained tree would arouse his enthusiasm and give him the greatest pleasure.

Samuel George Randall.—Mr. S. G. Randall, who was associated with the business and public life of Skegness for nearly half-a-century, died at Sleaford, Lincolnshire, on Friday, April 12, at the age of seventy-eight. He went to Skegness from Sandbeck Park, the seat of the Earl of Scarborough, and while an employee of his Lordship he planted practically the whole of the trees in the pleasure gardens, and carried out a great deal of other development work of this nature in the pioneer days of the Lincolnshire resort. Mr. Randall subsequently built up a successful florist and market garden business, and was one of the best known horticulturists in Lincolnshire. He was elected to the old Skegness Local Board, and later to the Urban District Council, on which he sat for many years, being Chairman in 1897-98 and 1909-10.

Friedrich Ries.—We regret to learn of the death, which took place on February 28, of Friedrich Ries, for nearly forty years in the service of the Parks Department of Karlsruhe, Germany, and from 1889 to 1917 Director. When he first came to the town, after a thorough and varied preparatory training, he was partly occupied in the street department, the open spaces being comparatively few and unimportant. During his term of service, however, and especially after he assumed full charge, the parks and other public open spaces increased enormously, and imposed an ever-growing burden which, however, he was only too willing to assume. Ries was a "giant for work," and not only performed most thoroughly the work necessitated by his office, but also found time for the raising of Petunias, a new variety of which he named "Karlsruhe Rathaus," and also —and above all— devoted himself passionately to the growing of Roses, which he loved and perfectly understood. All this imposed a serious strain on his strength, and in 1915 he was forced to apply to be placed on the retired list. The war conditions prevented this until 1917, but from then onwards he has lived in retirement at Durlach, being nearly eighty years old at the date of his death. It is, perhaps, a platitude to state that with him one more of the old school of gardeners has passed away, yet it is in his case particularly true. He was a master of his craft, and although in time his name may be forgotten, the exquisite parks and woodlands of Karlsruhe will bear eternal, although silent tribute to his genius and his toil.

James Vert.—The death occurred at Stowmarket, on Wednesday, April 10, of Mr. James Vert, Chairman of Messrs. James Vert and Sons, Ltd., nurserymen, seedsmen and florists, of Saffron Walden, at the age of seventy-six. He had been in failing health for some time past. Mr. Vert was a noted horticulturist, and for many years he was a successful exhibitor of fruits and flowers. He was head gardener at Audley End, Saffron Walden, to Charles Cornwallis, fifth Baron Braybrooke, and to Lord Howard de Walden, and when Lord Howard de Walden's lease of Audley End terminated in 1912, he removed with him and continued in his service at Chirk Castle, Wales, until his retirement four years ago, when he went to live at Stowmarket. Mr. Vert purchased the old-established business of Messrs. Webb and Brand, nurserymen, of Saffron Walden, about twenty years ago, and when it was registered as a limited company he became Chairman of Directors, and held the office until his death. He was twice married and leaves a widow and eight children. The funeral took place at Littlebury Churchyard, near Saffron Walden, on Saturday afternoon last.

ANSWERS TO CORRESPONDENTS.

Black Hamburg Grapes Failing.—*W. H. S.* It is difficult to give a reason why your vines have failed. You should have stated the age of the vines, and sent some roots and foliage for examination, besides stating the previous treatment given, as last season was a most favourable one for all vines young and old. Failures may occur from various causes, such as over-cropping; a cold, inert border that does not permit the free passage of air and water; too much organic manure; excessive dryness at the roots; or removing a quantity of fully developed foliage at one time. Any of these mistakes may have some bearing on the failure, and although the foliage may look healthy, if the borders lack potash and lime the results cannot be satisfactory.

Destruction of Yew Tree Stumps.—*H. C.* There is really no good way of quickly destroying tree butts that have been left in the ground. It is sometimes stated that by boring holes in them, filling the holes with saltpetre and allowing them to stand for several months, they may then be burnt by filling the holes with paraffin and setting on fire. In practice this rarely acts, although now and then some measure of success may follow.

Names of Plants—*G.* 1, Erica carnea var. alba; 2, E. carnea var.; 3, E. carnea; 4, specimen missing; 5, E. carnea alba; 6, E. cinerea alba; 7, E. carnea var.; 8, Forsythia suspensa; 9, F. intermedia. — *G.* 2. 1, Prunus subhirtella; 2, Forsythia suspensa. — *G.*3. 3, Ribes sanguineum var. atrosanguineum; 4, Epimedium pinnatum; 5, Saxifraga cordifolia var.; 6, Ribes sanguineum; 7, Ribes sanguineum var. carneum.

Pelargoniums Unhealthy.—*P. G. C.* There were no disease organisms present on the Pelargonium shoots, and the trouble is probably due to some error in cultivation. The constricted nodes suggest that the water supply is at fault. Great care has to be taken in the amount of water afforded the plants as they are going to rest in the autumn, and also as they commence growth in spring.

Treatment of Arum Lilies after Flowering. *L. B.* Opinion varies with regard to the treatment of Arum Lilies, but as success is obtained by either method, we suggest that you retain the one that has proved successful in your own case.

International Horticultural Congress, London, 1930.

As already intimated in these pages, the Eighth International Horticultural Congress, held in Vienna, Austria, in 1927, accepted an invitation from the Royal Horticultural Society to hold the Ninth International Horticultural Congress in London. It has been decided that this Horticultural Congress shall be held in London from August 7 to August 15, 1930, immediately before the Fifth International Botanical Congress, which is being held in Cambridge, from August 16 to August 23. The members of the Executive Committee appointed to make the necessary arrangements for the Congress are Professor B. T. Barker, M.A., of the University of Bristol; Mr. E. A. Bowles, M.A., V.M.H.; Mr. E. A. Bunyard, F.L.S.; Mr. F. J. Chittenden, F.L.S., V.M.H., Director of the R.H.S. Gardens at Wisley; Sir Daniel Hall, M.A., F.R.S., Director of the John Innes Horticultural Institute; Mr. R. G. Hatton, M.A., of the East Malling Research Station; Sir William Lawrence, Bt.; Mr. G. W. Leak; Mr. C. T. Musgrave, V.M.H., Dr. A. B. Rendle, M.A., F.R.S., V.M.H., of South Kensington Museum; and Mr. H. V. Taylor, O.B.E., B.Sc., Commissioner for Horticulture at the Ministry of Agriculture; with Colonel F. R. Durham, Secretary of the Royal Horticultural Society, as Secretary. Judging from the preliminary programme received, the Congress should prove immensely interesting to horticulturists, and it is therefore desirable that those whose aim is progress in matters horticultural should take part and express their intention to do so at an early date. The subscription for membership of the Congress will be £1, which should be paid to the Secretary of the Royal Horticultural Society, Vincent Square, S.W.1. The preliminary programme for the Congress is as follows:—August 7, Assemblage of Congress; August 8, Opening of Congress and Lectures in the afternoon; August 9 and 10, Excursions both days; August 11 and 12, Lectures both days; August 13, Excursions all day; August 14, Lectures in the morning, and Flower Show; August 15, Final Report of Congress by Chairman, Flower Show, and Close of Congress. The main subject for discussion at the Congress will be "Propagation, Vegetative and Seminal," for which papers and communications have been and are invited, and Dr. Van der Lek (Holland), Dr. R. J. Graham (Great Britain), Professor Priestley (Great Britain), Niels Esbjerg (Denmark), G. E. Yerkes (U.S.A.), Carl A. Dahl (Sweden), Dr. Webber (U.S.A.), Professor Faes (Switzerland), Franz Richter (France), Professor Denny (U.S.A.), Miss M. E. Reid (U.S.A.), Dr. Redcliffe Salaman (Great Britain), and Dr. Erwin Baur (Germany), etc., etc., have signified their intention of presenting papers. The Committee desires to point out that there will be other sections, and it is prepared to receive suggestions for papers for consideration. An extensive programme for visits to research stations and gardens of horticultural interest throughout the kingdom is being arranged. The Committees appointed at the Congress held in Vienna in 1927 will present their reports:—(I) On Nomenclature—in view of the Botanical Congress at Cambridge, this report, and the discussion on it, will be of outstanding interest; (II) On Awards; (III) On Colour; (IV) On Horticultural Institutions and Research; (V) On International Exchange of Young Gardeners; and (VI) On the Development of the International Committee. Communications made to the Congress by means of papers, or participation in the general discussion, will be permissible in English, French and German. Further information will be published in due course, and also sent to all who signify their intention of attending the Congress. All correspondence should be addressed to the Secretary, R.H.S., Vincent Square, London, S.W.1.

Gardeners' Royal Benevolent Institution.—Mr. Lionel N. de Rothschild, O.B.E., will preside at the eighty-fourth Anniversary Festival Dinner in aid of the funds of The Gardeners' Royal Benevolent Institution, at the May Fair Hotel, on Wednesday, June 26.

Daffodil Sunday at Kew.—At least a week before the Daffodils were at their best, Sunday, April 21, was, according to the daily press, Daffodil Sunday at Kew. Although not quite so luxuriant as in most seasons, due to the cold and dry weather, the thousands of visitors found plenty of Daffodils to admire in the grass and woodland. The varieties are planted mostly in groups and broad stretches of one variety, but there are also some very effective plantings in mixture near the main entrance and elsewhere. Not more than a dozen varieties are planted in large numbers, with the fine, rich yellow, trumpet variety Emperor in the greatest quantity. Most of the large plantings in the Arboretum were made twenty to thirty years ago, and the bulbs have not been disturbed since. In most places the Trumpet varieties predominate and are planted in groups and masses of varying sizes where, in the grass, or with the new growth of the Bluebells as a ground-work, they are much more effective than planted thickly in beds. In addition to Emperor, the Trumpet varieties planted in the greatest numbers are Empress, Victoria, Horsfieldii, Telamonius plenus and pallidus praecox. Of the other sections, Sir Watkin, Barrii conspicuus, Mrs. Langtry, Autocrat, Frank Miles, Stella, John Bain, poeticus praecox, and—the last to flower—the true poeticus, are found to succeed best naturalised in the grass at Kew. On the sunny slopes of the mound near Cumberland Gate, where they are the first to open, there has been a succession of Daffodil blooms for more than a month past.

Cornish Broccoli.—The Prime Minister's recent reference to the exportation of Cornish Broccoli to the Continent has drawn special attention to the cultivation of this crop. Up to about three years ago, the Broccoli produced in Cornwall was grown from local seeds and did not produce the firm, white curds which the market so desires. Seeds of superior strains were obtained through the agency of the Ministry of Agriculture, and Cornish Broccoli graded up in quality. A deputation of Cornish growers, with the County Horticultural Superintendent, visited the Continent in January last to examine the possibilities of marketing Broccoli at the more important centres there. As a result, they came back determined to try to sell on the Continent, to grade and pack the consignments, and incidentally to get permission from the Ministry to use the National Mark on them. The Ministry agreed and made regulations prescribing grades and marks, the whole organisation and arrangement being agreed to by the Cornwall Branch of the National Farmers' Union and the County Horticultural Superintendent. Seven growers applied for permission to use the Mark, and consignments were despatched to Brussels and Cologne.

The Genus Eucalyptus.—It would appear that the publication of the late Mr. J. H. Maiden's monograph on the genus Eucalyptus (*A Critical Revision of the Genus Eucalyptus*) under the authority of the Government of the State of New South Wales, is proceeding apace, as we have now received Part I of Vol. VIII (Part LXXI of the complete work), Part X of Vol. VII having been received barely two months ago. The present issue is a fairly comprehensive one, for in it thirty-eight Eucalypti are described, namely, E. Bucknelli, E. perplexa, E. conglomerata, E. tropica, E. pseudo-piperita, E. urceolaris, E. Callanii, E. pachycalyx, E. subviridis, E. McClatchie, E. Mortoniana, E. Dixsoni, E. Globulus, E. g. var. compacta, E. bicostata, E. St. Johni, E. pseudo-globulus, E. paradoxa, E. oviformis, E. niphophila, E. congener, E. nubilis, E. Grasbyi, E. Kochii, E. platycorys, E. Kingsmilli, E. scyphocalyx, E. Helmsii, E. concinna, E. ochrophylla, E. Nicholi, E. Crawfordi, E. glaucescens, E. Archeri, E. subcrenulata, E. Tindalae, E. Wilkinsoniana and E. nigra.

Gardens and Charity.—The scheme under which many of the most beautiful and interesting gardens in England and Wales were thrown open to the public in 1928 is to be continued this year. Through the great kindness of the owners, 727 gardens were opened between the months of April and September last year, and the generous response already made gives every reason to hope that there will be an even larger number this season. The scheme is organised by the County Nursing Associations and the Queen's Institute of District Nursing, 58, Victoria Street, London, S.W.1, from which address lists will shortly be available, giving the names of the owners and addresses of the gardens, and the dates on which the gardens are to be open. A charge of one shilling is made for admission, and this money is divided equally between the two nursing associations, so that the scheme not only gives pleasure to garden lovers, but helps to provide skilled nursing for those who are unable to afford the services of a private nurse. The Gardens Committee desires to take this opportunity of acknowledging the debt that is due to the many gardeners who give so generously of their time and skill in order to make the scheme a success.

Spraying Fruit Trees in Open Blossom.—The danger in spraying fruit trees when in open blossom with washes containing arsenate of lead is that visiting bees may be killed. The lead arsenate washes are certainly of great value in exterminating the Winter Moths, the larvae of which do considerable damage to the trees, but the spraying should be done either just before the blossoms open, or immediately after the petals have fallen. There may be some little difficulty in arranging this in big orchards, as the different varieties of fruits come into blossom at different times. Nevertheless, it should be aimed at, and certainly there should be no indiscriminate spraying of open blossom with lead arsenate. If any cases are noticed where bees die in numbers in such circumstances as are described, they should be reported to the Ministry of Agriculture, 10, Whitehall Place, London, S.W.1.

The "Classified List of Daffodil Names."—Among spring flowers, the Daffodil takes pride of place in English gardens, and it is appropriate at this season of the year to draw the attention of our readers to the standard reference work on Daffodil nomenclature—the *Classified List of Daffodil Names*—issued by the Royal Horticultural Society, and obtainable from its office, at Vincent Square, Westminster, price 1s. This list has been revised and brought up-to-date. The previous edition, published in 1927, is now exhausted, and since this was issued some six hundred names have been registered by the Society; these, together with a number registered by the National Daffodil Society of New Zealand, are included in the 1929 edition.

Celery Marketing.—At a well-attended Conference at the Midland Agricultural and Dairy College, Sutton Bonington, Loughborough, Mr. A. Jones, B.Sc., Advisory Economist, read a paper on "Celery Marketing." He pointed out that the bulk of the Celery grown in this country is in four areas—Lincolnshire, Cambridgeshire, Lancashire and Cheshire; that the acreage has increased from about 3,000 in 1918, to about 6,000 at the present time; that the increased area was partly to make up for the losses due to disease; that the work of Mr. Stirrup, on spraying, has resulted in heavier crops; that, in consequence, present production meets or more than meets present requirements; that, so far as the Lincolnshire area is concerned, the methods of marketing leave much to be desired; and that, in his opinion, Celery should be graded so that those who want the best may obtain it without having to purchase a certain proportion of inferior sticks in each bundle. As a complement to this paper, Mr. J. G. Murray, Horticultural Organiser for Lindsey, described his experiments in washing, grading and wrapping each stick separately in Celophane. He stated that the retailers obtained a quick and increased sale for such produce and were prepared to pay fifty per cent. more for it. Transport charges were reduced to one-half, and the produce was more acceptable to the shops and to the purchaser. He considered it extremely desirable to increase the demand for Celery, and this could only be done by offering it in a more attractive form. In his opinion, there is a great need for grading and washing by producers at some central depot near the point of production, and that in all probability it would be found an advantage to distribute the washed Celery in crates. The following points were brought out in the subsequent discussion:—Gluts are frequent at certain markets and could, by organisation, be avoided; crops have increased owing to the spraying experiments conducted by Mr. Stirrup, the Advisory Mycologist at the College; much Celery is too big and coarse for the better class consumers, and the retail price of Celery in shops is much too high.

Postponement of F.H.P.I. Conference.—We learn that at the request of the French delegation the annual Conference of the Fédération Horticole Professionelle Internationale, arranged to be held in London, in May, has been postponed until July 3, 4 and 5.

Moray Field Club.—The Annual Meeting of the members of this Club was held in Elgin, the Rev. George Birnie, B.D., President, in the chair. Mr. A. Millar, M.A., Alves, Secretary, gave a highly satisfactory account of the activities of the Club during the past season. The membership now numbers seventy-five, and eight field outings were held. At all of these the great majority of the members attended, with the exception of the joint outing with the Deeside (Aberdeenshire) Field Club. The venue then was rather far away for the convenience of the members, but the hope was expressed that a joint outing would again be arranged, this time nearer the Moray Club's headquarters. A syllabus was drawn up for the coming season's excursions as follows:—May 4, Elgin Cathedral; May 18, Roman Well, Burghead; June 1, Kinloss Abbey and Findhorn; June 15, Leuchars; June 22, Joint meeting with Deeside Field Club, if possible; August 31, Darnaway; September 14, Garmouth. All of these estates and districts should yield a vast amount of pleasure and instruction to those taking part in the outings.

Mr. C. S. Garnett.—Grandson of the late Mr. T. H. Garnett—formerly of Wakefield, and an enthusiastic cultivator of Japanese Chrysanthemums in the earlier years of their development as exhibition flowers—Mr. C. S. Garnett commenced his horticultural experience with Messrs. Horsmans, a firm of Bradford nurserymen and seedsmen that has now disappeared, but even during his school days he was greatly interested in gardening. When his family left the Bradford district he began that scientific training which has proved so useful to him as a consulting horticulturist and plant collector. The war period broke into his studies, but these were subsequently resumed at the University of Sheffield, with special reference to horticultural matters. In 1928 he organised and led a successful plant-collecting expedition to north-central Brazil, with Orchids as the special objective. Mr. C. S. Garnett contemplates another Orchid and general plant-hunting expedition to the mountainous regions of tropical South America. He possesses an interesting collection of Orchids and rare plants at Derby, and has conducted work on the raising of little-known tropical fruits.

MR. C. S. GARNETT.

Edinburgh Royal Botanic Garden Guild's "Journal."—The current issue of the *Journal* of the Edinburgh Royal Botanic Garden Guild is Part I of the second volume, and it is accompanied by the title page and index for binding up with the four parts of Vol. I. It was a happy idea that led to the publication in this issue of an account of Benmore and Puck's Glen, because of the association of the latter with the late Sir Isaac Bayley Balfour—a memorial dedicated to his memory—who was the first President of the Guild. Two illustrations, including the Memorial Rest Hut, accompany the account. "After Thirty Years" is a succession of reminiscences by Mr. D. MacIntyre, with a description of the Moanalua Estate of 8,821 acres he manages at Honolulu. "A few Malay Customs and Beliefs," by Mr. G. D. Forbes, sets forth the superstitions and customs that control the daily life of a Malay, from birth to death. Mr. D. Stewart, in discussing "Horticultural Teaching in the East of Scotland," indicates the facilities for horticultural training afforded by the horticultural section of the Edinburgh and East of Scotland College of Agriculture. In "The Dahlia in America," Mr. G. Masson makes an interesting statement which it would not be easy to substantiate, *i.e.*, "Up to 1912, Europe led in the development and introduction of better Dahlias, but that is not so now, for America not only leads, but has European varieties outclassed, so that we are exporting our better sorts to the Mother Country. As the Dahlia is a native of America, it is not to be wondered at that the States now lead the world in the development of all that is best in this glorious Fall Flower." Mr. G. White gives "Impressions of New Zealand," and draws attention to the fact that Blackberries and Gorse are two of the most noxious weeds in the country, and that "there are few openings for skilled gardeners, and large estates are non-existent." The rest of the *Journal* is occupied by domestic matters, including the names and addresses of members of the Guild.

Agricultural Research Bureaux.—In our issue for December 22, 1928 (p. 482), we announced that definite proposals had been laid before the Government for the establishment of a series of bureaux, or clearing houses, for the collection and interchange of information in eight branches of agricultural science. These proposals were accepted by the Government, and the governing bodies of the various institutes suggested as suitable for bureaux also gave their consent, with the result that three bureaux have already been opened. These are: The Bureau of Animal Nutrition, at the Rowett Research Institute, at Aberdeen, under the direction of Dr. J. B. Orr; the Bureau of Animal Genetics, at the Animal Breeding Research Institute, Edinburgh, under Professor F. E. Crew; and the Bureau of Fruit Production and Storage, at the East Malling Research Station, Kent, under Mr. R. G. Hatton. On May 1, the Bureau of Soil Science will be opened at the Rothamsted Experimental Station, under the control of Sir John Russell, and it is contemplated opening the remaining four bureaux during the coming summer. These are: Of Animal Health, at the Veterinary Research Laboratory, Weybridge, under Dr. W. H. Andrews; of Plant Genetics (other than herbage plants), at the Plant Breeding Institute, Cambridge, under Sir Rowland Biffen; of Plant Genetics (herbage plants), at the Welsh Plant Breeding Institute, Aberystwyth, under Professor F. E. Stapleton; and the Bureau of Agricultural Parasitology, at the Institute of Agricultural Parasitology, St. Albans, under Dr. W. Leiper. The movement, we are informed, has received the wide approval of the Governments of the Empire.

The late Lord Lambourne.—Lord Lambourne, the late President of the Royal Horticultural Society, left about £54,000, in addition to settled estate in Essex, Monmouthshire and Glamorganshire. He made numerous bequests to the Coldstream Guards and Masonic institutions, and left £500 to his keeper, Mr. F. West, and £200 to his Gardener at Bishops Hall, Mr. A. Bagg.

Guildford Gardeners' Annual Show.—The seventh Annual Show of the Guildford and District Gardeners' Association is to be held on July 17, in the grounds of Stoke Park, Guildford, and a very attractive schedule has been arranged. Numerous cups and medals are offered for competition, in addition to the money prizes, and, beside the horticultural classes, there is a special handicraft section. It is interesting to note in connection with this extremely active Association, that it continues to issue its *Monthly Journal*, in which are chronicled the activities of the Association, together with authoritative articles on various topical subjects. For instance, the issue for the present month contains reports of two lectures delivered before the Association; an article by Mr. W. Auton on the use of the watering-can; a review of the work for the month, and various notes and announcements. We notice that summer visits have already been planned to the gardens of Mrs. Joicey, Sunningdale Park; Sir W. Lawrence, Burford; and the R.H.S. Gardens, Wisley; and others are contemplated but have not been finally decided upon.

Types of Spades in Germany.—The English gardener is somewhat of a connoisseur in tools, and would probably be aware of at least half-a-dozen different kinds of spades, to be used for different operations in his craft; but it is doubtful whether there are so many kinds of spade-blades in common use in this country as there are in Germany. In that country, twenty-five different kinds are used, and all are named separately. They are:—Dachau, Elsass, Weinsberg, Rott, Leipzig, Dollendorf, Kirchheim, Spreewald, Ansbach, Schuh, Lüneburg, Bremen, Minden, Aurich, Hellweg, Weser, Oberschlesien, Berg, Kassel, Frankfurt (two), Lothringen, Rothenburg and Nürnberg. As will be observed, the spades are called after the districts where they are used; but they are not, of course, confined to these neighbourhoods.

Haarlem Daffodil Show. — Owing to the abnormal lateness of the flowering season, the proposed special Daffodil Show, to be held at Haarlem (Holland), has been postponed again, and will now be held on May 1 and 2.

Honour for Professor Hugo de Vries.—At the meeting of the Linnean Society of London, held on April 4, the President announced that the Council of the Society had resolved to award the Linnean Gold Medal to Professor Hugo de Vries, F.M.L.S., Lunteren, Holland.

Appointments for the Ensuing Week. — MONDAY, APRIL 29: Admiralty Horticultural Society's Spring Exhibition (at the Admiralty). TUESDAY, APRIL 30: Rhododendron Association's Exhibition (two days); Royal West Renfrewshire Horticultural Society's meeting. WEDNESDAY, MAY 1: National Carnation and Picotee Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. THURSDAY, MAY 2: Bideford and District Horticultural Society's meeting. FRIDAY, MAY 3: Manchester and North of England Orchid Society's Exhibition. SATURDAY, MAY 4: Leeds Paxton Society's Open Exhibition Night.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Sale of Plants at Ealing Park.*—The sale of Mrs. Lawrence's magnificent collection of stove and greenhouse plants commenced on Thursday last, and will be finished to-night. The first day was wet and cold; nevertheless, upwards of fifty people attended, consisting of the principal metropolitan nurserymen, several noblemen and gentlemen's gardeners, and one or two gentlemen. Among the latter we noticed, W. Upton, Esq., of Forest Hill, and H. Colyer, Esq., of Dartford. The plants were for the most part in good condition and realised, upon the whole, fair prices. When we were present on Thursday, some of the largest of the specimens were brought forward. We observed that the enormous Epacris grandiflora, which for many years formed the crown head of the Ealing Park collection at the Chiswick fêtes, was bought by Mr. Eyles for the Crystal Palace Company for £12 10s.; this fine plant was quite six feet high, and as much through, and covered with bloom. A Polygala acuminata of similar size, and also in flower, was put up, and fetched £10 15s.; this was purchased by Mr. Upton, who also became the fortunate possessor of a magnificent Azalea exquisita, for which he paid the handsome sum of £17 17s.; this plant was in all respects in excellent condition, and measured about five feet in height and six feet in width. The same buyer likewise purchased a beautiful Azalea variegata, four feet by five feet, for which £15 15s. was paid. An extremely good plant of Azalea Gledstanesi fetched £10 10s.; this was purchased by —Johnstone, Esq., of Oak House, Feltham. Azalea Lawrenceana (which did not appear to be different from Minerva) fetched the great price of £24 3s.; this was bought by Mr. Upton; it was certainly a splendidly-grown plant, measuring four feet in height and six feet in width. Azalea Apollo, five feet by four feet, fetched £8 10s.; and A. Gledstanesi, £7 5s. Azaleas altogether fetched good prices, as did greenhouse plants generally, although some Heaths, Eriostemons, Podolobiums, Indigofera decora and a few other things, sold for prices considerably below their value. Stove plants seemed less in demand than greenhouse plants, and therefore realised less money. Beautiful bushes of Ixora javanica, four-and-a-half feet in height, and three-and-a-half feet in width, only fetched £2 10s.; Dipladenia crassinoda, four feet high, and three feet through, 10s.; Allamanda cathartica, five feet high and four feet wide, £2 15s.; and other plants of this description fetched similar prices. The number of lots sold was 161; the principal purchasers, in addition to those already named, were Mr. Colyer, Mr. Ambrose Basset, of Stamford Hill; the Earl of Stamford and Warrington; Mr. Dods, gardener to Sir John Cathcart, Bart.; Mr. Walker, of Acton; Mr. James Veitch, of Chelsea; and Messrs. Fraser of Leabridge. Yesterday about the same number of buyers assembled, and a similar number of lots was sold, but they did not fetch near such high prices as they did on Thursday. The plants were, however, generally smaller. *Gard. Chron., April* 29, 1854.

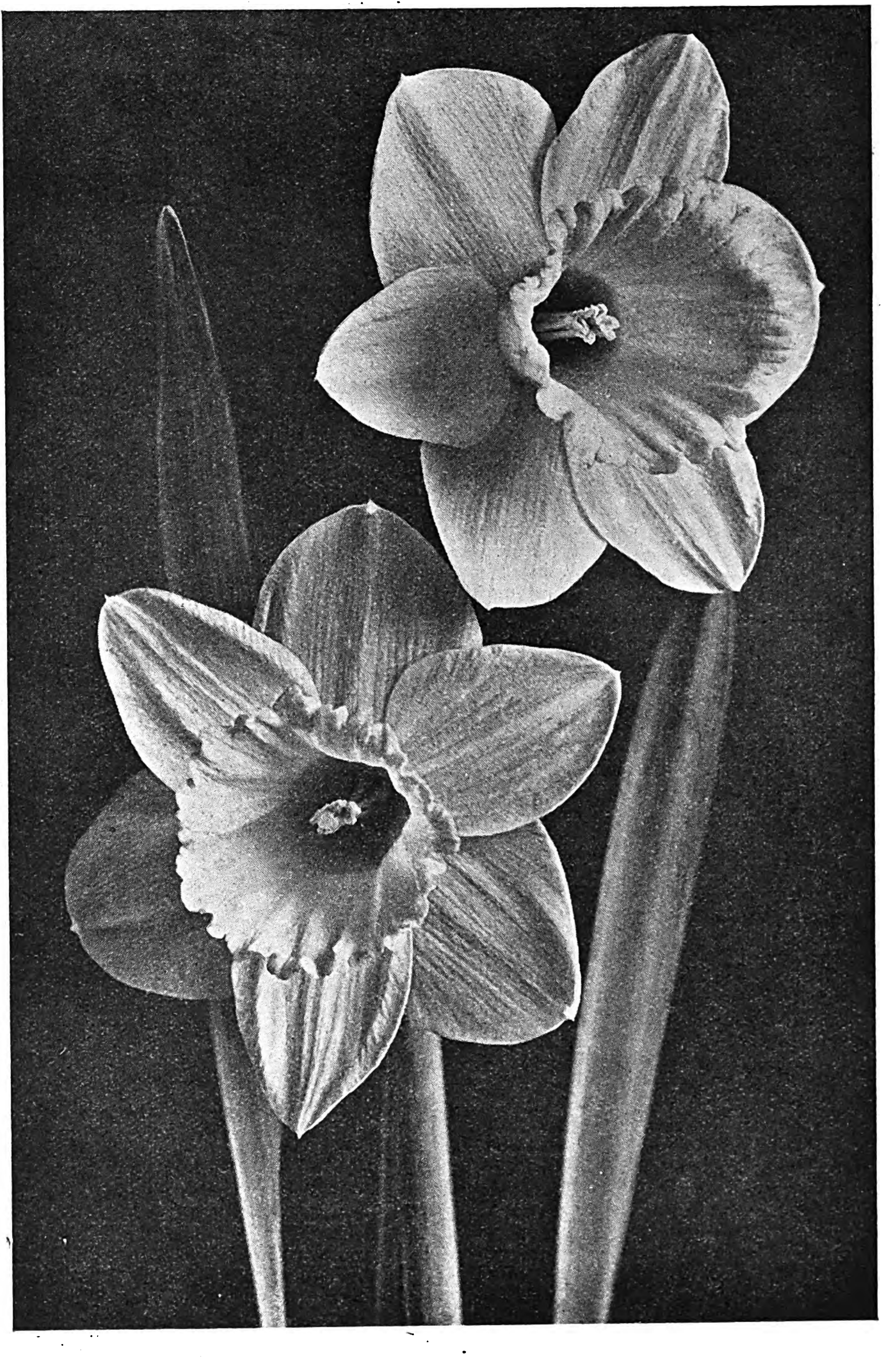

FIG. 154.—NARCISSUS GOLDEN INGOT.

R.H.S. Award of Merit, April 9. Flowers golden-yellow and primrose.

Shown by Mr. J. L. Richardson (see p. 285).

Publications Received.—*Your Flower Garden*, by Alfred E. Livingston; pp. 208, illustrated; Messrs. Crosby Lockwood and Son, Stationers' Hall Court, E.C.4; price 5s. net.—*American Rock Gardens*, by Stephen Hamblin; pp. 125, illustrated; *Garden Lilies*, by Isabella Preston; pp. 126, illustrated; The Orange Judd Publishing Co., New York, U.S.A.; price $1·25 each.—*Horticulture, Elementary and Practical*, by George W. Hood, M.Sc.; pp. 382, illustrated; Messrs. Henry Kimpton, 263, High Holborn, W.C.; price 15s. net.—*La Bizzarria*, by Professor Pietro Nati; reprinted, with Italian translation, by Dr. A. Ragionieri, Castello, Italy; price L.8.—*Daffodil Growing for Pleasure and Profit*, by Albert F. Calvert, F.C.S.; pp. 412, with 236 full-page plates; Messrs. Dulau and Co., 32, Old Bond Street, W.1.; price 21s. net.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Aerides, Saccolabiums, Vandas, etc.—Many species in these groups of lovely Orchids thrive under similar cultural conditions. Specimens that are now showing signs of activity should be given fresh rooting material, consisting of Osmunda fibre and fresh Sphagnum-moss. Strong-growing kinds—Vanda tricolor, Aerides Lawrenceana, Saccolabium giganteum, Rhyncostylis retusa, etc.—may be grown in pots, while smaller-growing species, such as Aerides maculosum and Saccolabium ampullaceum, are best accommodated in baskets or pans suspended near the roof-glass. Healthy plants that have retained their lower leaves well should have the old soil removed, and decayed roots cut away without disturbing the sound ones. See that the drainage is good, and work in fresh fibre and moss around the roots, adding lumps of charcoal as the work proceeds, and using a little extra moss for the surface. Plants that have lost their lower leaves should be turned out of their receptacles, and should have the lower portion of the stem removed to a point immediately below some good new roots, with a view to bringing the leaves down to the top of the receptacle. Arrange the plants and roots in position, then half-fill the pot with broken crocks and charcoal, carefully bending the roots in, after which fill in with compost, inserting charcoal as the work proceeds, and making it firm. Sufficient water should be given to moisten the compost through, after which very little will be required until the plants and roots are growing freely, when larger quantities will be required. They should be grown in a warm house. The surroundings and pots should be sprayed frequently in favourable weather; a humid and buoyant atmosphere should be maintained, and the plants will require shading from bright sunshine. Do not allow moisture to condense on the roof-glass during cold spells as the drips quickly damage the plants beneath. Vanda tricolor and V. suavis grow very fast and flower spikes soon develop; when this stage is reached extra water should be given to the roots. Vanda teres, V. Hookeriana, and the lovely hybrid Miss Joaquin, which have been kept dry at the roots during winter, should now be transferred to the lightest and warmest position in the warm house, where they may be syringed with tepid water several times daily during their growing season. These Vandas enjoy full sunshine, but as the flower spikes develop and expand, a little shade should be given to prevent the beautifully coloured flowers fading quickly. The stems should be fastened to teakwood stakes, and plenty of fresh Sphagnum-moss should be used about the roots. Vanda coerulea is now growing freely in a light, airy position in the intermediate house, and only requires shading from very bright sunshine. Plenty of fresh air should be afforded it on all favourable occasions, especially during warm nights. V. Kimballiana, V. Watsoniana and V. Amesiana also thrive under these conditions, especially as the weather becomes more genial, and the syringe may be used more frequently among them.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Apple Scab.—Apple scab or black spot is one of the most serious diseases with which the fruit grower has to contend, and its control, particularly in the case of dessert Apples, is of the utmost importance. Even when only slightly affected, the Apples are generally stunted in size and are quite unfit for table use. This disease attacks the shoots, the leaves and the fruits. During the dormant season it may be seen on the one-year-old shoots as brown, corky scabs, particularly on the varieties Potts's Seedling, Cox's Orange Pippin, Bismarck, and Dumelow's Seedling. From these shoots the fresh leaves are infected, and from the leaves the infection spreads to the fruits. The most favourable conditions for the spread of this disease in spring are cool and damp weather. Rain is essential before any movement of the spores can take place, but a period of only six or eight hours is considered sufficient. On the leaves the fungus appears as dark-coloured spots, mainly on the upper surfaces. The skin is eventually ruptured, and this results in the setting free of the spores, which infect the fruits. Apple scab may be controlled only by cutting out scab-infected shoots and by preventive measures of a fungicidal nature. The object of such treatment is to prevent the establishment of the fungus on the leaves. The best time to apply fungicides is when the trees are in the "pink bud" stage. This may be found impracticable in a private garden where a great many sorts are grown, therefore spraying when the earliest varieties are in the "advanced pink" stage should be practised. There should be a second application when the last of the petals are falling; and a third two or three weeks later if practicable. Fruit growers are not quite agreed as to the fungicide most suitable to apply at the "pink bud" stage. Some favour a Bordeaux mixture (6 lb. copper sulphate and 8 lb. quick lime to one hundred gallons of water); others a lime-sulphur spray (one part in forty of water). With the application of either there may be slight leaf-scorch, but that is dependent, to some extent, on the amount of sunshine immediately following spraying. It is important, where practicable, to apply the spray at a high pressure, through a nozzle which will give a fine, misty spray, just sufficient to cover the leaves, but without drenching. The second spray should be with lime-sulphur (one part in eighty of water) with 4 lb. of arsenate of lead added to each one hundred gallons of diluted spray to keep caterpillars in check and in the hope that it will also control Apple sawfly and codling moth larvae. The third spraying should be with lime-sulphur only. With Cox's Orange Pippin, the second spray should be reduced to one in one hundred, owing to the risk of spray injury to the foliage. When mixing a combined lime-sulphur and arsenate spray, it is important to dilute the lime-sulphur solution before adding the arsenate, and not the other way about, or chemical action is set up. The mixture should be used immediately. These fungicidal sprays are cumulative in their effect; and where the disease has been severe for some years the beneficial effect of the sprays may be more apparent in the second year, than in the first.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Planting Water Gardens.—Those who are fortunate enough to possess a stream or pond will find the adorning of it one of the most fascinating forms of gardening, for a great many of our most beautiful hardy plants are very effective when grouped by the margins of ponds or streams, and it is a matter of surprise that full advantage is not taken of them. When planting the banks of a pond the ground which projects out in irregular points should be chosen for the boldest plants, so as to produce a natural effect, and also to give the appearance of a larger stretch of water. Among foliage plants suitable for furnishing the margins of ponds, one naturally thinks of Gunnera manicata. This is one of the noblest plants for such a position; being a gross feeder, it is worth while to give the site for it extra preparation before planting, and an annual mulch to ensure that the leaves attain their full dimensions. Gunnera scabra, although small in comparison to the former, is also worth a place, while a colony of the dwarf Gunnera magellanica will prove an effective contrast to the large-leaved species. Rheums are also well worth places where plants with large leaves are required, and these, like the Gunneras, flourish in deep, rich soil. Among the best species are R. Emodii and R. nobile. Plants with more graceful foliage suitable for waterside planting are the various Gyneriums, and Cortaderia conspicua; the latter flowers much earlier than Pampas Grass, and for this reason will be found valuable in late districts. The Royal Fern, Osmunda regalis, may also be employed with effect.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Pot Vines.—These will have passed the stoning stage and, if all has gone well, the fruits should be approaching the ripening period. The roots should never lack moisture; the wall and floors should be damped regularly, and a free circulation of warm air, by fire heat, should be maintained throughout the colouring process. If the vines are heavily cropped and it is doubted whether the Grapes will colour well, a little extra air, more time, and a gradual lowering of the night temperature, supplemented by the use of soot-water and clear liquid manure at a temperature of 85°, will assist them greatly.

Figs.—The earliest pot Figs will soon exhibit a disposition to grow, which shows that fertilisation is completed, and the Figs will soon be mature. Less syringing, and a drier atmosphere, will therefore be necessary to obtain high flavour and good finish. Let the temperature during mild weather be 75° to 80°, and 90° after closing in the afternoon, gradually falling to 65° by the morning. Apply warm, diluted liquid manure frequently and syringe twice daily during bright weather to keep the trees clean, until the fruits show signs of ripening. Successional Fig houses may be kept at a temperature of from 55° to 60° at night, and 10° higher by day with sun-heat, until the trees have passed the flowering stage. Plants in later houses may now be assisted with a little fire-heat. If this is not practicable, close the house early in the afternoon, so as to secure so much sun-heat as possible, and syringe the plants on the mornings of fine days only.

Cucumbers.—Stop the shoots of vigorous plants, but where the plants have been in bearing some time, or have been overcropped, allow a little more freedom. Keep the temperature at 70° to 75°, with bottom heat at 85°, where plants have to be retained in houses. Fill up vacant frames as required, and cover up the frames at nights with mats until the end of next month. Plants in frames do not require so much water or feeding at this early season as those grown in pits or houses.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Gesneras.—The tubers of these plants which have been dried off should by now be thoroughly ripened. They may be turned out of the pots forthwith—a little care is necessary, otherwise the tubers may break—and repotted. The compost should be light and open, and may consist of equal parts of peat, fibrous loam and leaf-mould with plenty of sharp sand added; the receptacles should be well drained. As a rule, four or five of the strongest tubers may be placed in a six-inch pot, while the weaker-growing sorts may be grown in smaller receptacles. If started into growth in the receptacles in which they are to flower, some care is needed with regard to watering, otherwise the soil will have become soured before the roots are active. An alternative plan is to start the tubers by placing them thinly in shallow boxes or pans in a light compost, and when they are about two or three inches high, transfer them carefully to their flowering pots. Cover the tubers lightly and place them low enough in the pots to allow of top-dressing at a later date. Very little water is necessary during the early stages of growth, but a moist atmosphere is essential, also shade from bright sunshine in the early stages.

Malmaison Carnations.—One-year-old plants of the old Souvenir de la Malmaison Carnation will by this date have filled their receptacles with roots, and may now be assisted with some approved Carnation manure. Weak stimulants are to be recommended, and are best applied in liquid form; soot-water is also beneficial. This Carnation resents over-feeding, and if it is practised, the flower will, in all probability, show coarse centres; but when the plants are fed judiciously the flowers will show a marked improvement in quality. Aphides are very partial to these plants, which should be kept in check by occasional fumigations. Warmth from the hot-water pipes may be dispensed with, except on very cold nights.

Richardias.—As these plants pass out of flower and space is needed for other plants, they may be transferred to cool pits. Less water may be given at the roots, when the foliage will gradually die down until the plants come finally to rest.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunstar, Somerset.

Turnips.—Hoe between the rows of Turnips that were sown a few weeks ago, and when the seedlings are large enough to handle, thin them to from six to eight inches apart. A light dressing of soot hoed in between the lines after thinning will be beneficial in inducing quick growth. Another sowing may be made of the variety Early Snowball to provide a succession.

Potatos.—Maincrop Potatos should be planted without delay. Wood-ashes may be scattered in the drills after the tubers have been inserted, as the potash so afforded will be beneficial to the crop.

Peas.—A further sowing of mid-season Peas may be made for successional purposes, according to the requirements of the establishment.

Beetroot.—Long-rooted Beet may now be sown in ground that has been well tilled. The seeds may be sown in drills, or the ground may be made fairly firm and the seeds sown in holes bored with a crowbar and filled with sifted soil if long, specimen roots are desired.

Radishes.—These may be sown out-of-doors at intervals of five to six days, taking care not to sow the seeds too thickly. Mustard and Cress may also be sown in the open, in ground which may be kept moist.

Hoeing.—As the seedlings of the various vegetable crops come through the ground, no time should be lost in stirring the soil between the rows with the Dutch hoe. Onions, Carrots, Beet, Parsnips, Parsley, Peas, Turnips, etc, will benefit greatly by having the soil loosened about them, and this treatment will also keep weeds in check. Hoeing should be done regularly, at weekly intervals.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Globe Artichokes.—The past winter took heavy toll of these, even when protected, therefore, if young plants have been saved in frames, they should be planted out now in well prepared ground. Some of the old plants may yet break away, but few will be strong enough to yield heads this year.

Cutting Evergreens.—Yew and Holly hedges may now be clipped unless in very exposed places. Box edgings may also be clipped at an early date, where necessary, but where spaces occur it is better to replant the whole. The present time is ideal for this latter work, as growth is just starting. A little leaf-mould put in the trench and worked in among the roots will be advantageous, and if the soil is very wet or heavy, sand may also be added. Most evergreens transplant well at this season, and if the work is done carefully, not a plant should be lost. If large specimens, which have not been disturbed for years, have to be moved, it is advisable to sever the roots on one side the year previous to removal, to reduce the danger of the tree receiving too great a check. In warm, dry weather, copious waterings at the roots and overhead syringings assist greatly to re-establish the specimens.

Vegetable Marrows.—A few seeds of these should now be sown in heat and the seedlings potted up when they make the first rough leaf. Nothing is gained by sowing early, as the seedlings cannot be planted out before June, unless under lights, and stunted plants never do well. There are many varieties, but for general use Long White is most in demand.

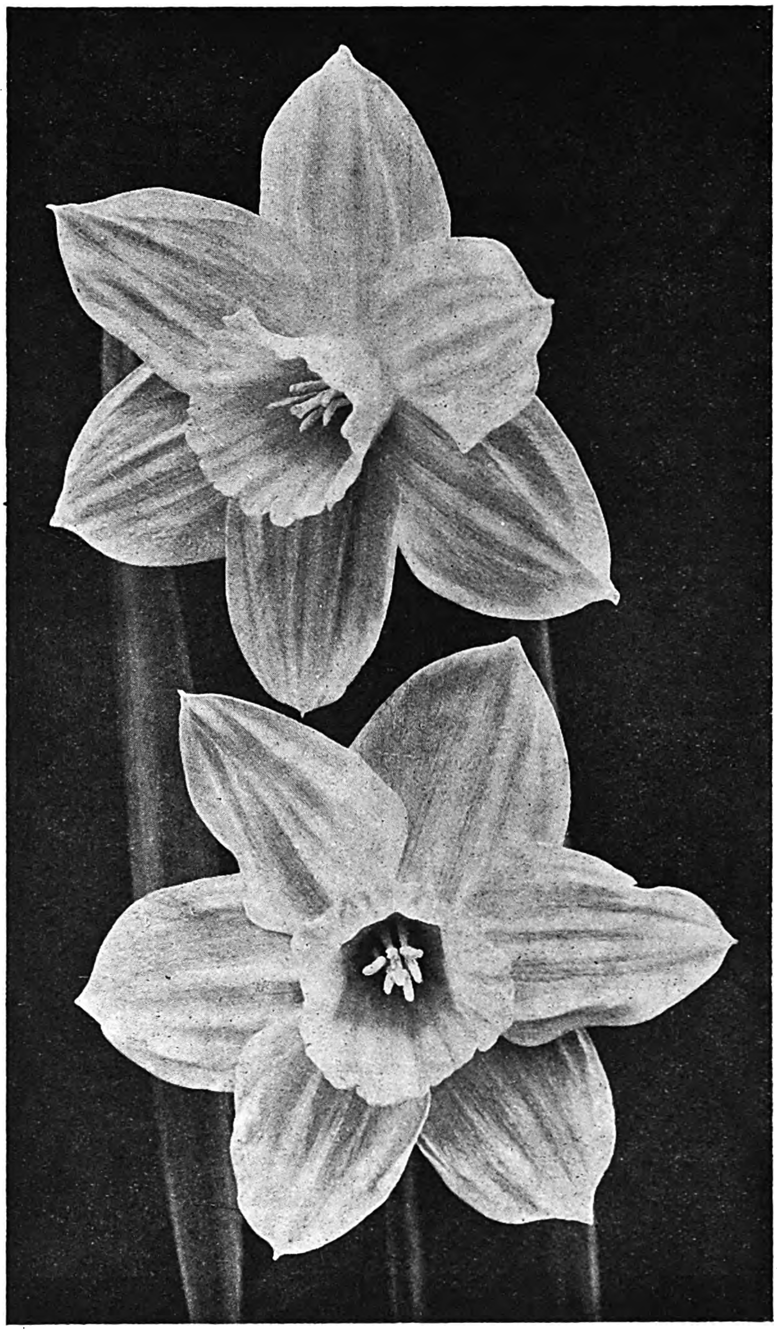

FIG. 155.—NARCISSUS SOLLERET.

R.H.S. Award of Merit, April 16. A Jonquilla hybrid; flowers rich golden-yellow. Shown by W. B. Cranfield, Esq., East Lodge, Enfield Chase (see p. 300).

Herbaceous Plants.—As the herbaceous plants develop growths the shoots should be thinned severely, all weak or crowded growths being pulled away, to allow the remainder room for full development. Phloxes, Heleniums, and, in fact, nearly all the occupants of the herbaceous border, will benefit by this treatment. Asters should be lifted and broken up, only the strong, young shoots from the outside being retained and planted singly. If cuttings of new or rare Michaelmas Daisies are inserted now in heat and planted out in May or June, with generous treatment they should make a fine show, much earlier than old plants, and if not planted too thickly, they do not grow so tall as usual, which is all to the good.

Cyclamens.—As the Cyclamens pass out of flower, water should be withheld gradually until the corms are completely ripe; the pots may be stood on a warm shelf or in a frame, fully exposed to the sun, until starting time arrives. Young plants should be encouraged by overhead sprayings and shade from bright sunshine. Do not allow them to suffer through lack of pot room, and stand them on a cool ash-bed, in a temperature of 60° to 65° as a maximum, falling to 55° at night.

Lawns.—After thoroughly sweeping the lawn, it should be rolled when the ground is moist until growth is sufficiently advanced to require cutting. A light dressing of sulphate of ammonia should be given unless a properly balanced lawn manure has already been applied.

PLANTS NEW OR NOTEWORTHY.

RHODODENDRON LEUCASPIS.

The interesting and attractive dwarf Rhododendron referred to in *The Gardeners' Chronicle* of February 16, 1929, page 128, as Rhododendron K.W. 6273, and figured in the issue of February 23, page 135, Fig. 69, proves to be a new species closely akin to certain members of the 'Boothii' series. In that series the flowers are usually yellow, but in this new species, to which the name "leucaspis" is given, the flower is almost a pure white—the flower colour and the flat face of the rotate corolla has suggested the specific name, "white shield." The plant was raised from seed collected by Captain F. Kingdon Ward, in the Upper Brahmaputra valley. The exact details of the locality from Captain F. Kingdon Ward's field note are given with the following diagnosis:—

R. leucaspis, Tagg, sp. nov.

Species sectionis Boothii ex affinitate R. megerati, Balf. f. et Forrest et R. sulfurei, Franch. a quibus floribus majoribus binis albis inter alia signa differt.

Fruticulus ramosus circ. 60 cm. altus, nunc paulo prostratus, nunc erectus; ramuli virides paulo setosi, (sub inflorescentia) circ. 3 mm. diametro. Folia petiolo 5–7 mm. longo vix sulcato flaccide setoso lepidoto suffulta; lamina ovalis vel elliptica vel paulo obovata, 3–5 cm. longa, 1·5–2·5 cm. lata, apice rotundata, basi obtusa vel late cuneata, margine setis crispatis praedita, supra atroviridis nitens sparsim pilosa atque lepidota, infra glauca papillata atque squamis flavidis conspersa, costa supra leviter sulcata infra eminente sparsim lepidota atque crispato-pilosa, venis primariis utrinque 6–8. Inflorescentia 1–3-flora, plerumque 2-flora; rachis tantum 3–4 mm. longa; pedicelli ad 1 cm. longi, bracteis plus minusve persistentibus semicelati, dense lepidoti. Calyx conspicuus, circ. 7 mm. longus in lobos 5 late ovatos vel obovatos virides vel roseo-tinctos basi lepidotos longe ciliatos fere ad basim fissus. Corolla rotata, clare alba, circ. 5 cm. diametro. extra lepidota, intus ad faucem pilosa; tubus 6-10 mm. longus, obscure 5-costatus, in limbum planum abrupte expansus; lobi late rotundati, basi auriculati, 1·5 cm. longi, 2·5 cm. lati, leviter emarginati. Stamina 10, subaequalia, 1·6–2·4 cm. longa, filamentis albis per partes tres inferiores villosulis, antheris 4 mm. longis. Gynaeceum 1·7–2 cm. longum; ovarium 4 mm. longum conicum squamis albidis dense lepidotum; stylus validus decurvus glaber vel basi sparsim lepidotus, stigmate late expanso.

Tibet: Tsangpo Gorge, at 10,000 feet. F. K. Ward, No. 6,273, in cult.

Captain Ward's field note of this number reads as follows:—

"Musi La, below Gyala, Tsangpo Gorge, 10,000 feet. 17-11-24. Bushy undershrub, sometimes more or less prostrate with ascending branches, or erect, 1-2 ft. high. Amongst Bamboo and other Rhododendrons on steep, grassy slopes, or on cliffs. Allied to numbers 6,250, 6,291." K. Ward No. 6,273.

As indicated by the collector, two other numbers are closely akin. The field notes for these are as follow:—

"Pemako, 8-9,000 feet. 24-10-24.

Epiphytic, hanging in long, loose festoons from the mossy trunks of big trees (Abies, Rhododendrons and Grande, etc.) in the middle forest. Petiole, pedicel and leaf margin with long, bristly hairs; under-leaf surface with scattered golden scales; ovary with scattered pale yellow scales. Truss 1–3 flowered. Calyx large, leafy, almost enclosing the ovoid capsule. Style (now) bent at right angles to the ovary. Fairly abundant." K. Ward, No. 6,250.

"Tsangpo Gorge, 8,000 feet. 20-11-24. Small, bushy or straggling undershrub of 1–3 feet, with long loose branches. Epiphytic on big, moss-clad trees in the middle forest with other epiphytic species. Allied to numbers 6,250, 6,273." K. Ward, No. 6,291.

Habit.—A bushy undershrub of 1–2 feet (the plant in cultivation constituting the type is a somewhat prostrate shrub of about one foot). Young shoots greenish, softly bristly; older wood brownish or reddish-brown.

Leaves.—Petiolate. Petiole 5–7 mm. long, not conspicuously grooved, softly bristly and lepidote. Lamina oval, elliptic, ovate or obovate, 3–5 cm. long, 1·5–2·5 cm. broad; apex rounded with a reflexed tuberculate mucro; base obtuse to broadly cuneate or semi-rounded, margin recurved, ciliate with long, crisped hairs; upper surface dark green, glossy, sparsely clad with long, thin, crisped hairs and also lepidote, both scales and hairs somewhat deciduous on old leaves; under surface greenish-grey, glaucous, papillate with wax-covered papillae, lepidote with yellowish, glistening scales which are a little more than their own diameter apart, midrib slightly grooved above, yellowish, prominent below and sparsely lepidote and very sparsely hairy with long, crisp hairs, primary veins about 6–8 on each side, very slightly impressed above, slightly raised below.

Inflorescence.—1–3 flowered (commonly 2-flowered); rhachis short, 3–4 mm. long; flower stalks encased in the more or less persistent bud scales, the outer of which are oval, pinkish, lepidote, with the margins densely fringed with short, soft, white hairs.

Pedicels.—Short, stout, not exceeding 1 cm. long, slightly curved below the calyx, densely lepidote.

Calyx.—Large, 6–8 mm. long, split to near the base into 5 broadly ovate, or obovate lobes; lobes greenish or pink-tinted, lepidote at the base, elepidote over upper two-thirds of length, fringed with long, curly, soft hairs.

Corolla.—Rotate, pure white, about 5 cm. across, lepidote outside, hairy within at the throat; tube 6–10 mm. long, 5-ridged, limb almost flat; lobes 5, broadly rounded, auricled at base and there overlapping, about 1·5 cm. long, 2·5 cm. broad, more or less emarginate.

Stamens.—10, sub-equal, 1·6–2·4 cm. long; filaments white, stout, hairy over the lower three-quarters of their length; anthers 4 mm. long, dark chestnut-brown.

Pistil.—1·7–2 cm. long; ovary 4 mm. long, cone-shaped, densely lepidote with whitish scales; style stout, curved downwards, whitish to pale green, glabrous, or with a few scales at the extreme base, expanded at the tip into a broad, 5-lobed, discoid stigma, 3 mm. across, with a central depression.

R. leucaspis promises to be of distinct horticultural value. It apparently flowers when quite young and very early in the year. Captain F. Kingdon Ward collected the seeds in November, 1924, and plants raised from these seeds have flowered in February and March as early as 1928. It is, perhaps, too soon to state anything about its hardiness.

In flower structure and foliage characters it seems to be very nearly akin to such members of the Boothii series as R. megeratum, although the majority of the members of that series have yellow flowers. The rotate corolla, the few-flowered truss, the distinctly down-curved style, the large calyx, are all in keeping with the R. megeratum group of the Boothii series; moreover, the leaf form, the ciliate margin, the scales of the leaf under-surface, and the leaf anatomy, suggest affinity with R. sulfureum and R. megeratum. As in the majority of the members of the Boothii series, the under epidermis of the leaf is distinctly papillate, with wax-covered papillae, which give the glaucous-grey colour, and the scales are sunk in small pits in the epidermis. The time of flowering, the small, elliptic leaves, glossy above and grey-green below, suggest, at first, relationship with R. moupinense, but the likeness is more superficial that phyletic. R. moupinense has a long, straight style and a funnel-shaped corolla. A nearer flower-structure affinity is with R. pendulum which, however, is quite different in foliage. Another series of the genus, the members of which have somewhat flat, rotate corollas, and sharply-curved styles, is the series Camelliaeflorum, but here again the foliage is unlike that of R. leucaspis. *H. F. Tagg, Edinburgh.*

TREES AND SHRUBS.

SPIRAEA BULLATA.

This rotund, dwarf shrub gives almost the appearance of having been clipped into shape, so tight are its dense masses of fastigiate growths, one foot high, clothed in dark green, crinkled leaves, which are broadly ovate and irregularly dentate. The small, flat corymbs of pink blooms are produced in lavish profusion toward the end of June, and they are borne at the ends of the current season's growths throughout July.

S. bullata is not very particular with regard to soil, but flowers most profusely in a sunny position. A little judicious pruning and thinning proves beneficial in spring, when growths taken from the base of the plant may often be induced to make roots of their own, if they do not already possess them.

This shrub is a native of Japan and is possibly a dwarf form of S. japonica. It has been cultivated since 1881, and is known also by the name S. crispifolia. Although not cultivated extensively at present, S. bullata is one of the best deciduous-flowering shrubs for the rock garden or the front of the shrub border. *Graham S. Thomas, Botanic Garden, Cambridge.*

CORYLUS COLURNA.

Apart from the purple-leaved forms of Corylus Avellana and C. maxima, one does not, as a rule, associate the Hazels with ornamental plants in the garden, although the common Hazel is one of the most attractive features of our native landscape, where, however, it is not brought into competition with plants culled from floras much richer than our own. Here, it fits into the economy of things, and its beauty no man will deny. Pleasing to the eye in spring when festooned with countless catkins, and in the autumn something to satisfy the most epicurean taste. Nightingales, too, consider a Hazel copse a fitting theatre in which to pour forth their inimitable song, and what more could any plant desire!

These thoughts were created by the sight of a very imposing specimen of Corylus Colurna in flower. This species will hold its own with any of the denizens of the garden. It has all the qualities of a first-rate plant, and on account of its stately habit, commends itself as a specimen tree. The typical mode of growth is a short, stout trunk from which arise a series of lofty branches, reaching a height of thirty-five feet to forty feet or more, giving the plant a fine pyramidal outline. The bark is a pale greyish-brown colour, and peels off in irregular patches.

C. Colurna is remarkable for the length and profusion of the male catkins, which are borne in clusters of three to five, and are often six inches long. The colour, a greenish-yellow, will not improve on close inspection, but to be thoroughly appreciated the plant must be viewed from a short distance. The effect of the myriad of long, graceful, drooping catkins is at once striking, combining a light and airy daintiness with the dignity of a stately tree. A specimen caught in the rays of the sun on a bright spring morning is an object of scintillating beauty. The female catkins are, of course, insignificant, but are attractive on account of their protruding crimson styles. The nuts are partially enclosed in a remarkably large and curiously-fringed involucre. The leaves are four to six inches long, two to four inches wide, heart-shaped at the base, and have irregularly toothed margins.

C. Colurna is widely distributed, occurring in south-east Europe, Asia Minor and the Himalayas. As it survives the cold winters and extremely hot summers obtaining in these regions, it is quite amenable to our climatic conditions. It is stated to have been introduced into this country about the seventeenth century, but has suffered neglect, and deserves much more attention. It should be given consideration for a position where a good deciduous specimen tree is required. The Himalayan form of C. Colurna is sometimes described under the name C. Jacquemontii. *Thos. Blythe, Botanic Garden, Cambridge.*

HARDY FLOWER BORDER.

POTERIUM OBTUSUM.

This beautiful Japanese Burnet has not been so long in cultivation as to have become common, although it has already achieved distinction as a valuable herbaceous border plant, attractive both in foliage and blossom.

For P. obtusum is hardy and a vigorous grower, forming a basal mound of foliage from which arise, during July, branching stems to a height of three feet or more, terminated by slender, gracefully arching flower spikes of rosy-crimson, light and airy in appearance owing to the long, coloured stamens, which constitute the charm of the inflorescence. P. obtusum should be planted in cool, deeply-worked and moderately rich soil, and may be increased by division.

Another desirable member of this Rosaceous family is P. canadense, which attains a height of four or five feet, and has highly ornamental, glaucous-green foliage, and long, fluffy, creamy-white inflorescences, produced profusely during autumn, and useful for cutting. P. canadense is seen at its best when massed on the margin of a pond or lake, in cool, deep soil.

P. tenuifolium, also with whitish inflorescences, is sometimes grown, also P. sitchense, which rarely exceeds more than two feet in height when producing its purplish inflorescences, and, like P. canadense, is best suited to moist positions; although P. canadense does not object to a position at the back of the herbaceous border, where it may be grown with effect.

Our native Salad Burnet—P. Sanguisorba—although with no pretentions of handsome appearance, is yet not without charm when naturalised in the wild portions of the garden, in warm, dry situations, or in sunny grassland, to which its flower heads of green and purple will impart an attractive, misty appearance. *M. W.*

ALPINE GARDEN.

ALLOSORUS CRISPUS.

There are now so many rock plants grown in our gardens, hailing from the four corners of the globe, that we are apt to neglect some of those which grow nearer home. Bright colours are essential to any garden, but too often one misses the little shady alpine glen with tinkling brook or silent pool, and devoted mainly to a collection of plants other than those which bear flowers. For such a position, Ferns are admirably suited, and they form a beautiful foil for the Candelabra Primulas and other plants requiring a moist situation and a certain amount of shade.

Year by year the list of small Ferns continues to lengthen, and now there are many varieties, forms, and sub-forms of desirable species which are both useful and beautiful, despite their frequently cumbersome botanical names. Nevertheless, there are several species which are deserving of attention without recourse to varietal forms, and of these the Parsley Fern stands predominant, partly on account of its curious leafage, and also because it is a plant which, while it naturally resents a dry position and full sun, is less insistent upon shade and moisture than many other species.

Allosorus crispus (Cryptogramme crispa of Robert Brown) grows wild over a large area of the northern hemisphere and, except in the extreme north, inhabits mountainous districts. It is a native of Britain, being found in several localities, but chiefly in Scotland and in the northern counties. The stock is tufted, and the light green foliage is not unlike that of Parsley, especially the outer fronds, which are barren. The central fruiting fronds are taller than the barren ones, but the whole plant rarely exceeds twelve inches in stature in the most favourable circumstances.

Those attempting to grow this Fern should imitate the natural conditions under which the plant is found. It should be accorded a cool position, preferably facing north, at the base of a large boulder, provided the drainage is good. The soil may be a fairly spongy mixture of loam, leaf-mould and peat, but its texture would have to be governed by the position available. Although the plant fully enjoys moisture when growing rapidly in summer, it must have fairly sharp drainage. For this reason, and for the fact that it naturally inhabits rocky situations, small pieces of rock should be buried in the soil and scattered around the plant, in much the same way as one would treat Daphne Blagayana. It would be interesting to try A. crispus in a rock-cleft, into which water drains from moist ground above; if the rocks are well placed the passage of water would keep the cleft uniformly moist, without becoming stagnant at any season.

The late Mr. Malby grew this species in the moraine, but it is quite possible that he found the plant throve equally well in other situations which would provide a more natural setting. For instance, if the intending cultivator of A. crispus has a rocky bank in a woodland dell, where the trees afford partial shade, he would do well to try it in this position. The proximity of rock of a porous and yet absorbent nature is an additional advantage, and the writer has seen specimens growing quite well in partly-shaded pockets among half-buried sandstone blocks and rubble, the soil being of a peaty nature and the slope gradual. *L. B. C.*

WOODLAND GARDEN.

VIOLA CANADENSIS.

This robust and decorative Violet is a native of Canada and the United States, ranging in the former country from Newfoundland and Quebec to British Columbia, and ascends the Rocky Mountains to a considerable elevation above sea-level. The finest specimens both with regard to stature and size of flowers, are usually found in deciduous woodlands, luxuriating in the deep leaf-soil, beneath or in the shade of Maples and other trees. In mountainous situations it is usually dwarf and compact.

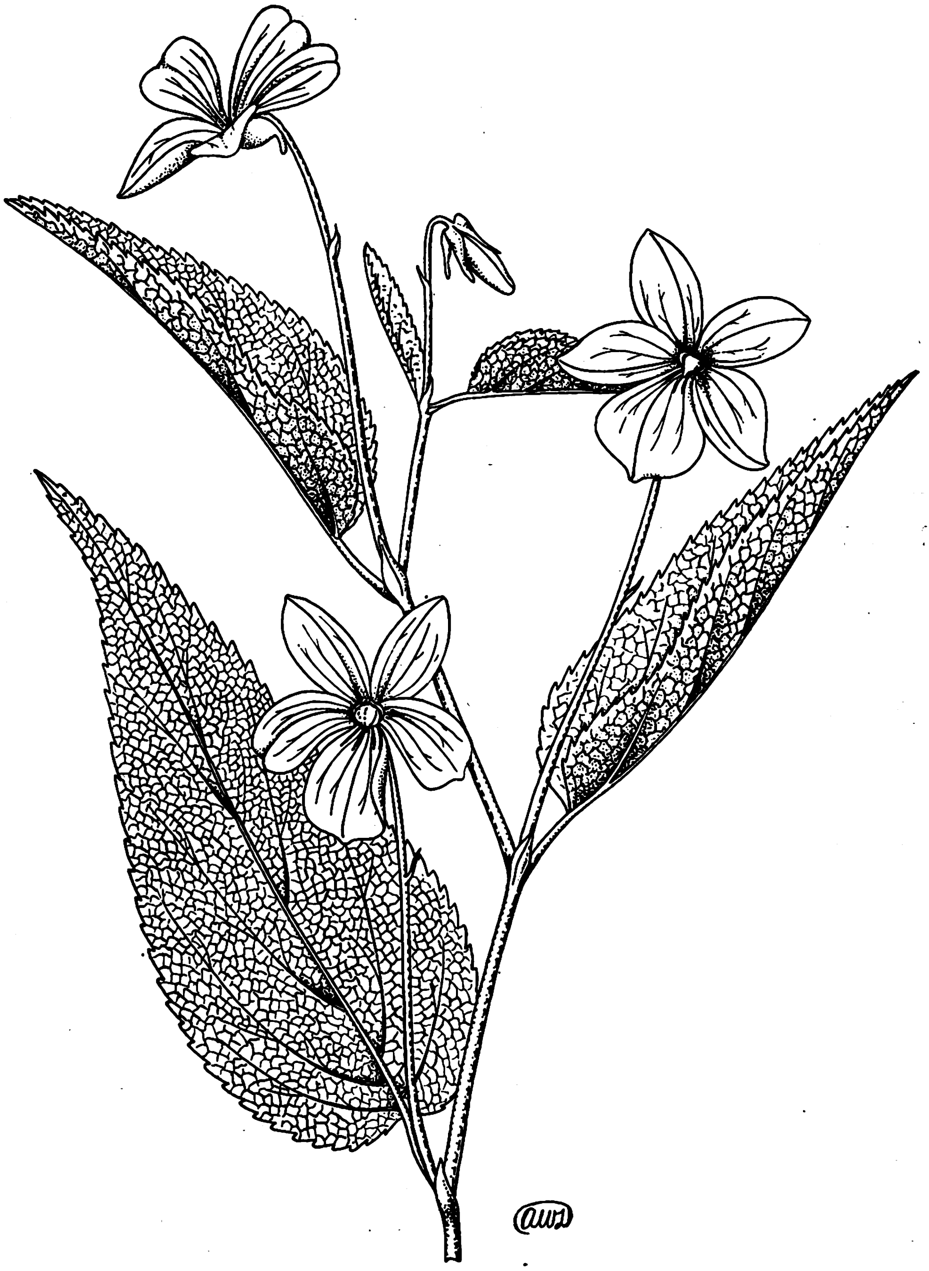

FIG. 156.—VIOLA CANADENSIS.

Viola canadensis (Fig. 156) produces a clump of rich green, strongly-veined, smooth foliage on more or less erect stems, six to twenty-four inches tall, bearing numerous beautiful blossoms on long, slender stems which spring from the axils of the leaves; they vary from white tinged and veined with purple, to pale mauve tinged with pink; the spur in this species is remarkably short. The plant blossoms from April to June, and may be grown easily in a damp, half-shady spot in leaf-soil and loam. *A. W. D.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XIX.—MARKING TIME.

APRIL 26 saw us on the move again, still heading up the valley, east of north. It was alleged to be two marches to where the Delei river splits in half, at Watersmeet, as we named it, and, owing to unforeseen causes, we actually took a day and a bit; but it was not really more than a decent day's march, along an easy path. Ever since leaving Chibaon we had kept high above the river, and we still did so. From one spur we had a fine view up the valley of terrifically steep, igneous ranges, barren and repulsive, enclosing the furious river. I quite expected that we were coming to a Pine-clad country; but although the bare framework of the mountains often showed through the thin covering of grass and trees, the latter were always Oak and Alder; and higher up, where the clouds clung persistently, was the usual forest.

At the end of the first day we camped at a village whence we could see many snow-covered peaks, now much closer; but with the mountains as steep as houses, and the valleys as deep as trenches, there seemed little prospect of the country opening out, or the forest changing its spots. However, next day we passed through a lot of cultivation and saw not only large patches of Opium Poppy, carefully fenced in, but Wheat and Barley. That, at least, indicated a change for the better, and I had hopes of a Tibetan settlement ahead, where more gentle slopes seemed to suggest pastures, if not new methods of tillage. Two hours' march brought us to Tablekon, above Watersmeet, where we found grass huts of low degree ready for us, pitched in the midst of cultivation and surrounded at a distance by the same old Mishmi huts. The altitude was about 5,250 feet. We had a clear view up the north-west branch of the Delei river, and it did not look encouraging; the view up the north-east branch, at the head of which was supposed to be the pass, was blocked by a high spur. Above the cultivated slopes was the forest, with Tsuga trees nearer than we had seen them yet, and although the snow-bound peaks on both sides of the river were also much closer, they looked, if possible, more inaccessible than ever. However, after two months of effort, we believed ourselves to be at last within striking distance of the pass. Disillusionment followed swiftly.

The day was wonderfully fine, but the atmosphere was rather milky, and in the middle of the day a more than usually fierce gale raged for two hours. That prepared the way for bad weather, and for the next six days it rained steadily, with brief intervals, although the rain did not prevent us going out and taking a look round.

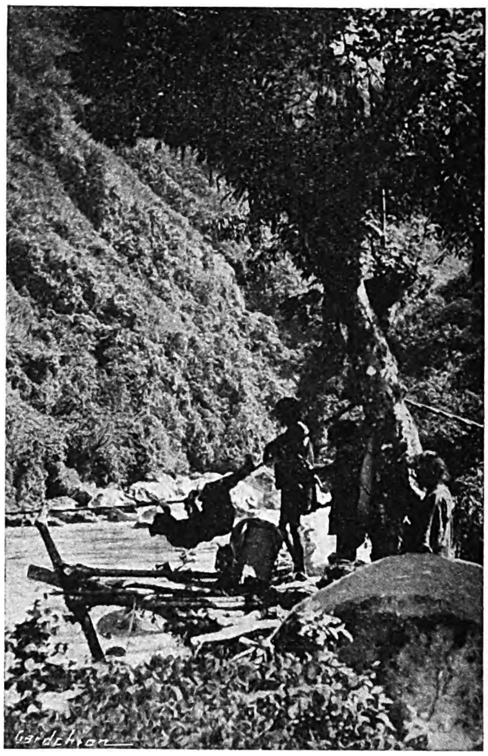

FIG. 157.—CROSSING THE DELEI RIVER BY A MISHMI ROPE BRIDGE.

On our first excursion to a nearby glen, where a fine cascade crashed over a cliff, we got covered with leeches. A pale violet-bearded Iris grew on the cliff under the drifting spray and just out of reach; a few plants found on the stony bank below might have been washed down from above, and did not flower. Within reach, on the drenched cliff, was a common-looking 'Diptera' Saxifrage, and another bright yellow, fleshy Saxifrage. By the stream, I noticed Veronica, Violets, Buttercups, Cardamine, a small Mimulus, Impatiens and a Myosotis with minute flowers. The Violet was worth more than passing notice. It was a good-sized plant, producing long runners, and flowers on stalks two or three inches high, at least, in fruit. The flowers were white, expanded, like the wings of a butterfly, the base of the spur alone being dark violet. In fact, the flower looked like nothing so much as a small, white butterfly with a violet body, in full flight. The plant is quite glabrous, and the leaf-margin is crenate. Another somewhat similar species is found here, but it can be distinguished from the above by the fact that it is slightly scabrid all over; the leaf, too, is drawn out into an acuminate apex, and the margin is serrate instead of crenate. It is not so common as the first mentioned species.

Another day I visited some cliffs up the side stream. Every stream now, big or little, was walled in by sheer gneiss cliffs, generally bare, and every tertiary stream dropped over a precipice which might be anything from 500 feet to 1,000 feet high. In flower were Campanula colorata, Didissandra lanuginosa, Arisaema, Cynoglossum, and Geranium; not in flower were species of Begonia, Chirita and Orchids. On May 3, we crossed the next stream and climbed the shoulder above, from which we hoped to get a clear view, if not of the pass, at least up the valley. However, once more we were disappointed. The river carved its way in a semi-circle through a deep, dark gorge, and the view was quickly shut out by immense spurs; far from broadening out, the valley grew ever narrower. Thus it became evident that the head of the valley was not, as I had supposed, ice worn, and that the Delei river was simply a flank stream which, rising on the southern face of a great range, had carved a narrow valley, for itself—a gorge rather. We had walked into a hopeless cul-de-sac!

The path around the arc of rock which formed one wall of the gorge was a succession of breakneck climbs up and down notched logs; the face, being partly in shadow, and well watered from above, was covered with a thick growth of shrubs, some of which were flowering gaily; Philadelphus, a pink Deutzia, Euonymus, the 'Aureum' Rhododendron; either already over, or not yet in flower, were Rhododendron dendricola, Corylopsis himalayana, Abelia, Ilex, Quercus, Hydrangea, Skimmia and so forth. Until the rain ceased, we could not hope to do another march, as the coolies naturally refused to risk their lives, although we subsequently discovered that when it became necessary to do this dangerous march under the worst possible conditions, they were equal to the occasion.

There was the usual difficulty over coolies here—the Mishmis were busy in their fields, cleaning, planting and collecting Opium. The Poppy crop was evidently a valuable one. An average-sized plant produced from three to five capsules, each an inch high and more than an inch through, yielding perhaps R.5 worth of Opium. Thus the smallest patch, containing not less than 200 plants, might be worth anything from a thousand rupees upwards. Much of this would be used locally, of course, but it is reasonable to assume that some of it, at any rate, finds its way to Sadiya, where it is sold, legally or illegally—probably the latter. Enterprising Tibetans are active in the dope-running business.

The Opium is collected by the old women who come out in the early morning and scratch the fattest capsules, wiping off the buff-coloured juice as it exudes on a piece of rag. After a day's rest, the same capsule is cut again, and so on for several days, until it is scarred all over and every drop of latex has been exuded. When one piece of rag is thoroughly clotted with the poison, another is taken; and to remove the Opium it is simply steeped in water—for the Mishmis do not smoke Opium, they drink it! Like all the other hill tribes, they smoke incessantly, men, women and children, but they smoke Tobacco leaf, in pipes, and grow it themselves. They were very fond of the cheapest brand of cigarette, the sort of smoke which in India can be bought for a penny a dozen. The Mishmi system of cutting the Poppy capsules must be entirely empirical, and it might well be that experimental research in this direction—when to cut, how to cut, how long to rest between tappings, and so forth, would yield interesting results, just as it has with the Para Rubber tree.

We were able to buy Peas again here, although they were long since over in the villages down below; but sweet Potatos were 'off,' although we still had a good supply in stock. Fowls were very scarce, and exorbitant. We had to climb about a thousand feet from our camp in order to reach the forest, and having discovered a path, we started off on May 5 to see what we could find. After passing through a belt of Oak forest, where the ruby foliage of sapling Quercus semi-serrata was conspicuous, we came to Tsuga, then Rhododendron sinogrande and other tree species, and finally into a sharp ridge crowded with Rhododendrons, chiefly a glorious 'Barbatum' in full bloom (Fig. 159), and a smaller 'Campylogynum,' allied to R. tephropeplum. The 'Barbatum' trusses were large and tight, the flowers white, pink, or white banded with pink, more or less freckled with purple within, and always with a small, dark purple flush, like an ink-stain, near the base.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, and 30; and April 13, 1929.

The range of colour according to the depth of spotting, and the amount, was considerable; the dark green leaves, too, were a fine cinnamon beneath. The trees were flowering freely, and I regarded this as quite one of the best 'Barbatums' I had ever seen. However, it is not new; I collected it in the Di Chu valley in 1926, but did not see it in flower; it looked attractive, and here was the confirmation. The 'Campylogynum' was an altogether smaller plant. It was a shrub with smoky-grey leaves and purple-pink flowers; I would have put it down as R. tephropeplum, but for the fact that the truss carried seven or eight flowers instead of three or four. They are closely allied species.

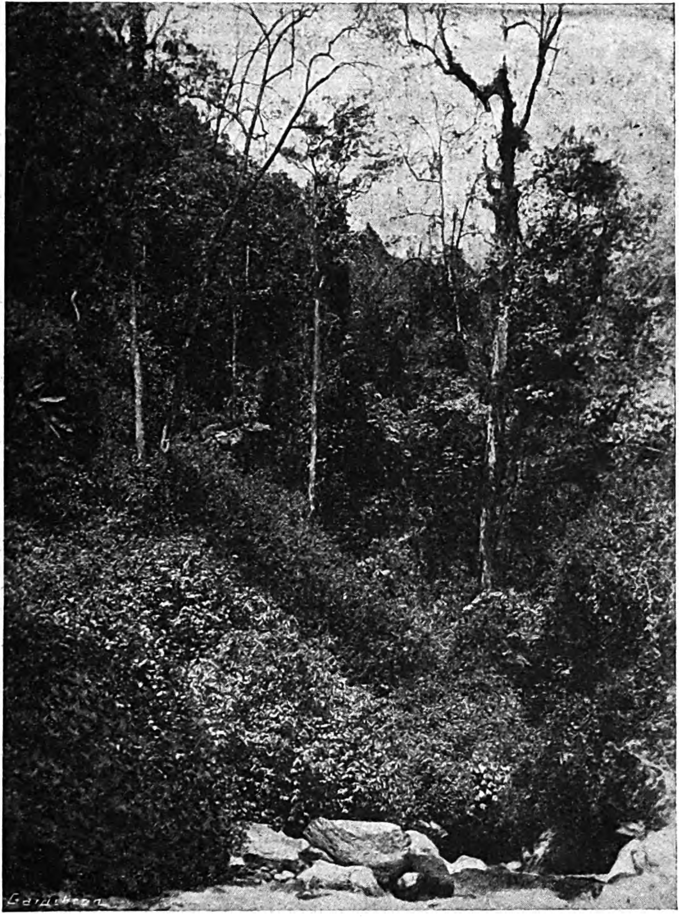

FIG. 158.—TROPICAL RAIN FOREST IN THE DELEI VALLEY, 4,000 FT. ALT.

The tree on the right is Altingia excelsa.

Another small tree which was in full bloom, filling the dark forest with moon-beams, was Viburnum Wardii, gleaming coldly white. Meanwhile, lured on by this treasure trove, I had outstripped my companion, and presently found myself alone; the lunch ration was with him. Now, from the position of the sun, I judged it was time to return, but after leaving the ridge I missed the way. Instead of turning back, I went on down through the forest, from time to time traversing in the direction I believed the path to lie, hoping thus to cross it. The going became worse and worse, and I was unlucky enough to strike a part of the forest where the undergrowth was really dense. At last, just as the sun was sinking behind the opposite range, I came out into the open, and saw the river far below. The worst was yet to come, however; I had passed from the frying pan into the fire with a vengeance! I now found myself in abandoned cultivation, where the dense secondary growth made progress even more difficult than in the forest; the bushes and Brambles grew so high that I could not see where I was going, and twice I came to the brink of a precipice, and was forced to retrace my steps. At last I found a way down into the valley, where, about dusk, I picked up the main path some distance below our village; it was nearly eight o'clock when I got back to camp. Buttercup, who had lost both me and the path on the way up, had abandoned the ascent, but always loyal, waited for my return several hours on the mountain, and did not get back himself until five; he was greatly relieved to see me, fearing I had met with an accident.

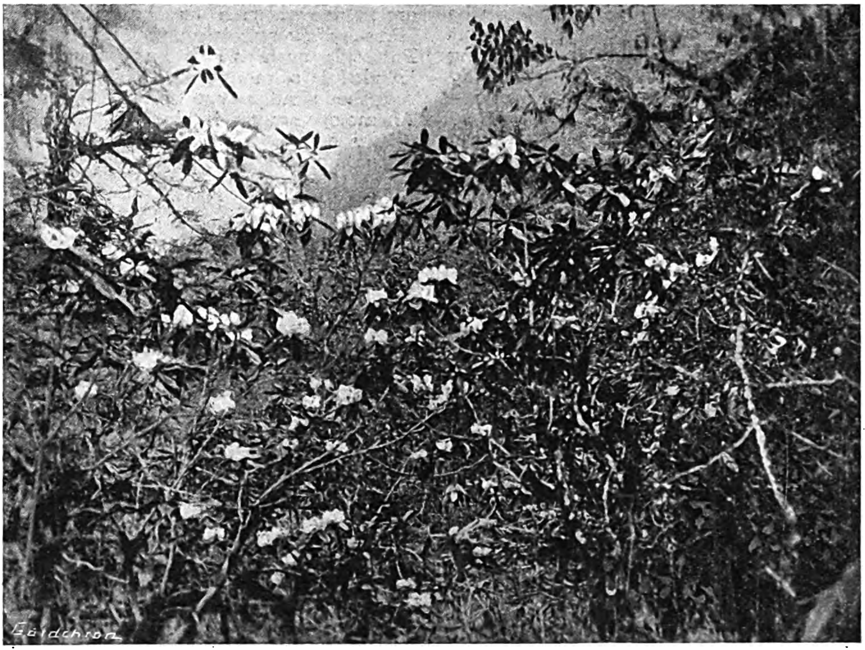

FIG. 159.—EARLY RHODODENDRONS; A BEAUTIFUL SPECIES OF THE 'BARBATUM' SECTION.

I still had the bunch of Rhododendrons I had gathered, but they were a sorry sight after my struggles in the rough. *F. Kingdon Ward.*

NOTES FROM A WELSH GARDEN.

Although so many of the Wallflowers were killed by the frost, one of them not only came through unharmed, but is to-day (early April) in better bloom than it has been for years. This is the variety Harper Crewe (also known as Miss Hope), perhaps the best of all the old yellows, with an individuality quite its own. Its small, buttony, double flowers are closely arranged in upright, finely-tapered spikes, and the sepals of the opening buds, being a tawny-bronze, add an additional warmth to the richness of their yellow. Erysimum linifolium has been completely destroyed, so that a long desired combination of its lavender with the pale citron-yellow of Cheiranthus alpinus var. Moonlight, must for another season be counted among "the hopes that triumphed and fell dead."

Cruciferous plants are apt to dominate the April rock garden, but one can scarcely have too much of the double-flowered Cardamine pratensis, and some of the Aubrietias are not to be scorned whatever the purist may have to say. A plant of Magician, or Vindictive, or Gloriosa, or Lavender, well-grown, can be pleasanter company than many a disgruntled alpine, and the splendid courage with which such plants have restored their frost-bitten foliage and covered the scars of winter with fresh green and bountiful blossom, is enough to give the most dismal of Jeremiahs fresh hope. Although not often seen, those two forms of Aubrietia usually listed as A. argentea var. variegata and A. aurea var., are worthy of note. Both are rather shy growers, but the small, round flowers in a soft lavender are delightful, squatting close upon the low mats of the silver or the yellow, the former variety being much the smaller of the two. Arabis Sturii is also a cheery little Crucifer with goodly-sized flowers of a sound white on three-inch stems. With pink-flowered Arabis, little satisfaction has been derived here. Many have been secured under various names, but most of them are too much alike, and all seem to stop short of being good enough for choice company.

Aethionema (Eunomia) rotundifolium is a small, creeping species, which does not often show us any more than its low, tufty mat of blue-grey leaves, but a frosty winter and dry spring have induced it to produce a quantity of pale-pink flowers, nestling among the metallic foliage. Much like this in its close, dwarf habit and glaucous-blue leaves is Veronica telephifolia. In an old stone trough, this wee Speedwell of Ararat has been bearing a cheerful crop of clear, pale-blue blossoms since the middle of March. Not unlike V. saxatilis, but at least a fortnight earlier, is the creeping V. satureioides, which brightens the rather sullen violet of its large flowers with prominent anthers of a ruddy crimson. Trifolium uniflorum is a pretty little thing for a close-up ledge, making a small, compact cushion of bronzy foliage, which is now decked with short-stemmed Pea-flowers in rose and white. Near this is another mite of a mighty race, Euphorbia pilulifera, which threads its way between the stones of a hot, dry wall, here and there putting forth a glaucous-leaved rosette bearing a posy of yellow only about two-eighths-of-an-inch across. Another Liliput with yellow flower-clusters of microscopic dimensions which must not be overlooked, is Salix retusa var. serpyllifolia, which occupies a ledge of cool, moist soil. This is surely the minutest of all shrubs.

Aethionemas, like Lithospermums, have been rather a sorry sight since the frost, but some plants of the peerless A. Warley Rose came through and are flowering well. Potentilla Thomasiniana, a Dalmatian species, has made a lovely mat of its downy, silver-green leaves which are nearly hidden beneath the short-stemmed, yellow-flowers. Most of the Saxifrages are showing their appreciation of a dry winter and drier-spring, the 'Mossies' being unusually firm and sturdy. The rock garden Phloxes are equally happy. mainly because they have got away before their arch-enemy, the slug, whose coming has been delayed. There are so many delightful Phloxes of the subulata and Stellaria groups that a novelty which will stand out in conspicuous splendour among such a host of good things must be a plant of uncommon quality. Even so, such a one has arrived in P. Camla, which is only just beginning to flower here, and to which I hope to refer some other time.

The weather conditions have suited Primula marginata admirably, the type species and one or two colour forms, notably P. m. var. Rhenainia (perhaps a hybrid) being first-rate. The exquisitely beautiful P. Linda Pope is also commencing to show its large, blue-lavender, mealy-eyed blooms. P. hirsuta, with rose-pink flowers, is a cheerful little alpine, and among a set of the P. pubescens (nivalis) class the rich crimson Faldonside, the deep blood-red Ruby, and Mrs. Wilson, will not escape admiration. The last is not so good a colour as many of its section, but its extraordinary vigour and wonderful fragrance are qualitites of no little value. P. glaucescens is another happy thing that can be recommended to any who are on the look-out for an easy, early, permanent, free-flowering Primula of its kind. P. rosea is especially charming just now, covering its wintered mound of shrivelled foliage with golden-eyed flowers in the most exquisite of pinks. Moreover, this beautiful species has sent its seedlings travelling all around a small pool, and there are few things more attractive in the garden than this family of pretty adventurers.

Among the Erythroniums "now showing," those of the E. revolutum section, notably the creamy-white Watsonii, the bright rose Johnsonii, and the paler pink, Pink Beauty, are conspicuous for their size, colours and elegance. The lilac and mauve E. Hendersonii is also very attractive, and a peculiarly entrancing one lately seen in a friend's garden was labelled E. grandiflorum var. robustum. This variety stands nine inches high, and the large, reflexed flowers are a bright buttercup-yellow. The anthers are white or red, and the long, tongue-shaped leaves unspotted. In the cool soil which these supremely graceful things enjoy are the Shortias, now coming into flower. Sanguinaria canadensis is pushing its milky-white flowers out of its dove-coloured leaf-scrolls, and in a scree-bed close by an old colony of the lovely Anemone vernalis is blossoming with its accustomed freedom.

There is no more beautiful grouping in the garden at the moment than a low, spreading bush of Magnolia stellata, bearing quantities of blossom, underneath which is a broad azure drift of Omphalodes cappadocica (cornifolia), while beyond, at the water's edge, are the big yellow spathes of Lysichitum camtschatcense. In this company is Rhododendron ciliatum which, although a very young plant, is carrying several trusses of bloom. This is not a reliable species here, and it is, of course, very apt to lose its flowers in spring frosts. But its big, campanulate flowers are so beautiful with their shell-pink exterior and pearl-white lining, their delicately-frilled margins and delicious scent, that R. ciliatum is a species one must count among the indispensable. Another deliciously fragrant shrub which is flowering well and whose blooms will expire with a very few degrees of frost is Osmanthus Delavayi. Camellias are usually regarded as rather tender shrubs, and many of them probably are. But some of the C. japonica class are so hardy that one in particular, var. Donckelaarii, had not so much as a leaf discoloured by the recent frost, and it is now carrying a fine crop of its semi-double, crimson blooms.

Erica arborea was the first of the Tree Heaths to succumb last February. It was killed outright, yet E. a. var. alpina growing close by escaped without the slightest harm. Precisely the same thing happened in a neighbour's garden, and the incident is significant in demonstrating the extraordinary diversity in the hardiness between a variety, or form, and the type; E. australis, oddly enough, survived the ordeal unscathed and entirely without protection. Even in the hill-top garden referred to, this fine species came through the frost without a leaf being browned and the thermometer there ranged between 22° and 25° for several days. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

NOTES FROM WISLEY.

The recent alterations to the rough piece of ground between the Bamboo walk and the rock garden, and the formation of an alpine meadow, are now beginning to bear fruit, and already there is much of interest to be seen in this portion of the garden. The grass is now studded with Crocuses and Narcissus Bulbocodium, and drifts of blue are formed by the flowers of Chionodoxa Luciliae and Anemone blanda. Many of the St. Bavo type of Anemone are also coming into flower. Plants of Gentiana verna are now being planted out, but it remains to be seen whether small subjects such as these will not be overwhelmed by the grass, the vigour of which, however, is checked by the poverty of the soil.

In the rock garden itself many Anemones are in flower, such as the intensely blue A. Hepatica var. angulosa and varieties of Anemone Pulsatilla, such as Farrer's pink variety and the delightful salmon-pink Mrs. van der Elst. A rather similar type of Windflower is seen in Anemone vernalis, having white flowers with a yellow centre. One of the most attractive features of this plant is the soft brown fur with which the buds are invested. Many Saxifrages are in bloom on the rock garden, including Saxifraga Burseriana minor and S. oppositifolia. Good varieties of the latter include S. o. latina, a good grower, and S. o. W. A. Clark, with extremely vividly-coloured blooms. Bulbs in flower on the rock garden include Scilla bifolia carnea, with white flowers flushed with pink; and Chionodoxa Luciliae alba, certain flowers of which are not completely white but present an opalescent appearance which is not unattractive. A few interesting Daffodils are also in flower in the rock garden; Narcissus maximus is blossoming freely, as are a hybrid between Narcissus cyclamineus and N. poeticus, and N. capax plenus with pretty little double, sulphur-yellow flowers.

The alpine house now seems to have completely recovered from the great frost and is full of interesting things, among which may be mentioned Primula Baileyana, a deep lavender-flowered Primrose, introduced by Captain Kingdon Ward, the blooms of which are fragrant, and speckled with farina. Another rare Primula in bloom is P. eucyclia, which scarcely exceeds one inch in height. The flowers are pink and the whole plant suggests a miniature Crane's-bill. Better known are Primula hirsuta and P. marginata, of which there are good specimens in flower. A handsome hybrid of the latter is Primula Marvin (marginata × venusta). There is also a large-flowered, thrum-eyed plant of P. Winteri named Wilbrook Seedling, and a huge-flowered form of P. acaulis (Evelyn Arkwright) which has nothing to distinguish it, save its large size.

One of the prettiest little plants in this house is Jeffersonia dubia, a native of Manchuria; it has incompletely cordate leaves and delicate, lavender flowers. Another pretty plant which has quickly thrown off the effects of the frost is Rhodothamnus Chamaecistus, a tiny shrub now covered with pink blossoms. Other dwarf shrubs in bloom include the very fragrant Daphne Blagayana. The number of buds on Daphne rupestris (petraea) is also noteworthy. Among the smaller and less showy plants which are apt to be overlooked, mention may be made of Androsace pyrenaica, which makes a tight cushion of green. It is now in bloom, and in spite of the very small size of the flowers in the case of some specimens, they almost entirely hide the foliage.

In the alpine house frames some uncommon bulbous Irises are in bloom, namely Iris orchioides and I. bucharica. They have yellow and cream flowers and pale green foliage.

In the wild garden, Rhododendron lutescens is in bloom, but is not very effective. R. praecox has flowered well, but the frost has completely spoiled the bloom, which is so susceptible that the usual methods of protection do not seem to be of any use. Some of the blooms of Pieris japonica have also suffered from late frosts, which have been very severe. Fortunately, the cold does not seem to have affected plants of Corylopsis spicata which are flowering well, and which in previous years have often been spoiled. Bamboos, however, such as Arundinaria nitida, present a sorry spectacle even in the most sheltered parts of the gardens.

A visit to the upper trial grounds is well worth while, for there are flowering some of the late Mr. W. R. Dykes' collection of Tulips, among which are some most beautiful forms of T. Kaufmanniana, the colours ranging from cream and pink to deep yellow and scarlet. In bloom with the latter are Tulipa Sprengeri and T. turkestanica, which has several flowers on one stem. In company with the Tulips are planted other bulbs, such as Scillas, and among these are Scilla cappadocica and S. cilicica, the latter a most graceful little plant somewhat like S. sibirica, but having a more open flower. The largest-flowered Scilla in the gardens is S. sibirica var. atrocoerulea, with monster blooms, of which there are a great number open near the main entrance to the Laboratory.

Many of the plants on the Laboratory walls are still looking very unhappy, but it is pleasant to record that Berberis Fremontii, with its distinctive glaucous foliage, has withstood the cold well, and is now making its new growth, that is bright red when it first appears. A somewhat similar plant, but with longer leaflets, also planted against the Laboratory, is Berberis haematocarpa. *J. E. Grant White.*

NOTICE OF BOOK.

The Perfumes of Flowers.

The new edition of Vol. II of Mr. W. A. Poucher's work on Perfumes, Cosmetics and Soaps,* is a handsome and very adequately illustrated book. The work is well-known as an authoritative treatise to all those engaged in the manufacture of perfumes and cosmetics. Moreover, the book contains a great deal of information of interest to the general reader, and especially to those attracted to horticulture.

The cultivation of sweet-smelling flowers and aromatic plants for perfumery purposes is an important branch of horticulture, which has its headquarters at Grasse, near Cannes, in the south of France. The industry is also carried on in many other parts of the world, including our own country, whose moist climate is specially adapted for the cultivation of Lavender and

---

* *Perfumes, Cosmetics and Soaps, with Especial Reference to Synthetics*, by William A. Poucher, Ph.C.; Vol. II, being a *Treatise on Practical Perfumery.* Third edition (enlarged and revised). 8½ ins. × 5½ ins., pp. xiv—521—45 plates. London: Chapman and Hall, Ltd., 11, Henrietta Street, W.C.2. Price 25s. net.

Peppermint destined to be distilled in order to obtain their essential oils.

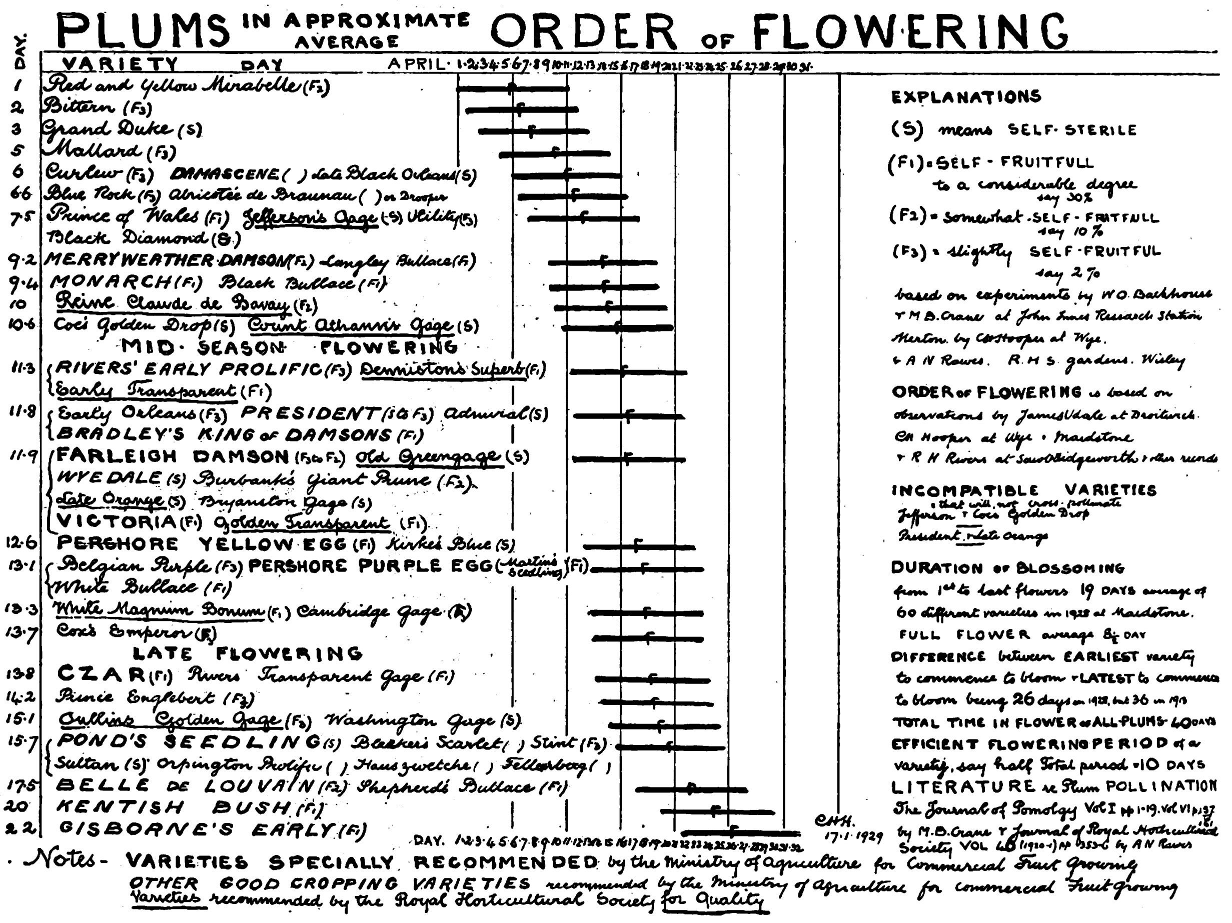
Mr. Poucher's work opens with an extremely interesting historical sketch in which the progress of perfumery is traced down the ages from remote times. The earliest floral perfumes appear to have been made by steeping sweet-smelling flowers in Sesame, Olive and similar oils. Perfumes of this type, so well as incense made from various aromatic gums and resins, were employed by the ancient Egyptians. They also made use of cosmetics of various types, especially kohl, a black paint for darkening the eyebrows and eyelashes; and, among the many illustrations adorning the book under review, are photographs of a number of ancient Egyptian kohl vases from the British Museum collection.

In the second chapter, various theories are discussed which have been put forward from time to time to account for the formation of perfume material by plants, and the part played by this material in the economy of plant life. Full details are also given of the various methods adopted for the extraction of the perfume, a task which calls for considerable care, since, owing to the complex chemical character of the odorous material it is very liable to be spoiled during the process of extraction. The most important method is distillation in the presence of water, whereby an immense number of essential oils are obtained. Finer products, however, are procured by the methods known as "enfleurage" and "extraction with volatile solvents." In the first, extraction of the perfume material is effected by means of solid fats in the cold. In the second, the odorous substances are dissolved from the flowers by means of an easily volatile solvent, usually refined petroleum spirit, which can be removed by subsequent distillation.

The sixth chapter will be read with great interest by all flower lovers, as it consists of monographs on the more important plants whose delightful odours are reproduced in handkerchief scents and various perfumed cosmetics. In certain cases, such as, for instance, those of the Rose, Jasmine and Mimosa, use is made, at any rate in high-class products, of material obtained from the flowers in question, supplemented with other suitable odorous substances. In other cases, the appropriate odour is obtained entirely by means of synthetic chemical products and substances derived from other plants, instances being afforded by Cyclamen, Lilac, Hawthorn and Sweet Pea odours. In these monographs, full botanical and chemical details are given concerning each species, as well as particulars of the cultivation of those species which are grown for perfumery purposes.

The main bulk of the book may be stated to constitute a series of illustrations showing how the various perfume materials, both those obtained from plants and those of synthetic origin, can be used, every conceivable type of perfumed cosmetic being dealt with.

We owe a big debt to the perfumer for making available for our delight the fragrance of flowers when these are no longer in bloom, and Mr. Poucher's book is a very admirable account of the practical side of this little known art. *H.S.R.*



EXPLANATIONS

(S) means SELF-STERILE

(F1) = SELF-FRUITFULL to a considerable degree say 30%

(F2) = somewhat SELF-FRUITFULL say 10%

(F3) = slightly SELF-FRUITFUL say 2%

based on experiments by W. O. Backhouse & M. B. Crane at John Innes Research Station Merton, by C. H. Hooper at Wye, & A. N. Rawes, R.H.S. gardens, Wisley

ORDER OF FLOWERING is based on observations by James Udale at Droitwich, C. H. Hooper at Wye & Maidstone & R. H. Rivers at Sawbridgeworth & other records

INCOMPATIBLE VARIETIES & that will not cross-pollinate
Jefferson & Coe's Golden Drop
President & Late Orange

DURATION OF BLOSSOMING
from 1st to last flowers 19 DAYS average of 60 different varieties in 1928 at Maidstone.
FULL FLOWER average 8½ DAY
DIFFERENCE between EARLIEST variety to commence to bloom & LATEST to commence to bloom being 26 days in 1928, but 36 in 1913
TOTAL TIME IN FLOWER of ALL PLUMS 40 DAYS
EFFICIENT FLOWERING PERIOD of a variety, say half Total period = 10 DAYS

LITERATURE re Plum POLLINATION

· Notes - VARIETIES SPECIALLY RECOMMENDED by the Ministry of Agriculture for Commercial Fruit Growing
OTHER GOOD CROPPING VARIETIES recommended by the Ministry of Agriculture for commercial Fruit growing
Varieties recommended by the Royal Horticultural Society for Quality

ORDER OF FLOWERING AND POLLENATION OF FRUIT BLOSSOMS.*

(Continued from p. 299).

PLUMS.

Plums are grouped according to pollenation experiments into three classes:—1, those that are considerably self-fruitful; 2, those that are absolutely or very nearly self-sterile; and 3, a few that are partially or slightly self-fruitful. The most self-fruitful group includes:—Pershore Yellow Egg, Pershore Purple, Victoria, Czar, Denniston's Superb, Monarch, Shepherd's Bullace, Kentish Bush, Early Transparent, Prince of Wales, Bradley's King of Damsons, and Gisborne's.

The partially self-fruitful varieties include:—Rivers' Early Prolific, Early Orleans, Cox's Emperor, Prince Englebert and Belgian Purple, while the self-sterile varieties include:—Pond's Seedling, Green Gage, Jefferson, Bryanston Gage, Late Orange, President and Coe's Golden Drop.

Of the self-fruitful varieties Pershore Yellow Egg Plum fruits perfectly in Worcestershire without another variety, and yields as heavily as Potatos, but all the other kinds yield more heavily if pollenated with pollen of another variety.

Some suggestions based on pollenation experiments and orchard practice may be found useful:—Rivers' Early Prolific crops well with Prince of Wales, Czar or Monarch; Pond's Seedling with Czar or Kentish Bush; Belle de Louvain with Czar or Kentish Bush; Monarch and Rivers' Early Prolific or Prince of Wales; President with Czar; Victoria with Czar; Oullin's Golden Gage with Pershore Purple.

For the three specially shy bearing kinds, namely Coe's Golden Drop, Green Gage, and Bryanston Gage, Mr. M. B. Crane, of the John Innes Horticultural Institution, states that for Coe's Golden Drop he has found Pond's Seedling, Rivers' Early Prolific and Monarch to be good pollenisers; for Green Gage he has found Pershore Yellow Egg, Pond's Seedling, Czar, Early Orleans or Bradley's King of Damsons to be good pollenisers, and for Bryanston Gage, Rivers' Early Prolific.

At Wye there is an interesting fruit garden of four acres enclosed by a circular wall about nine feet high; on this wall are trained trees of different varieties of Plums, and there are three hives of bees in the garden. These shy-bearing Plums all fruit here almost as plentifully and regularly as the Victoria. Mr. Crane finds Late Orange and President to be inter-sterile, and in like manner Coe's Golden Drop and Jefferson; so one should avoid planting these varieties together for cross-pollenation.

The accompanying table shows the approximate order of flowering of Plums.

(To be continued.)

---

* A paper read before the Royal Society of Arts, Wednesday, February 13, by Mr. Cecil H. Hooper, F.L.S., of Wye, Kent.; Mr. H. V. Taylor, O.B.E., Commissioner for Horticulture, Ministry of Agriculture, presided.

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Snowdrops.—Everybody loves the Snowdrop; it is beautiful as a small clump in a cottage garden, clothing the bare ground under deciduous shrubs, or spangling the grass and clustering about the buttress roots of giant trees. Perhaps the place where it is most at home is among the moss and decayed leaves in thin woodland; here, too, it suffers least of all from inclement weather and the stalks are longer and more suitable for arranging in bowls, etc. There is no difficulty in its cultivation, for it will grow anywhere; but for some reason it is rare to see it comfortably established. Enough Snowdrops have probably passed through bulb merchants' hands, and the London sale rooms, to carpet the gardens of England. What becomes of them? Many sold in late autumn are already half dead, having been out of the ground when they should have been making roots; consequently they fail miserably. Late summer or autumn may be the best seasons to buy and sell Snowdrops, but now is the time to divide and replant them in positions where it is not likely that an unskilled man will dig or fork—" out of sight, out of mind " is an old proverb—and, indeed, disturbance is too often the cause of disaster in the case of the lowly Snowdrop. It is sacrificed and buried by the forking necessary to control the weeds. When left undisturbed for a few years the bulbs will increase rapidly, and self-sown seedlings spring up, although the latter take several years to reach the flowering stage. *J. Comber, Nymans.*

Narcissus minimus.—This delightful little Daffodil opened its first blooms here on a sunny rock slope, on March 24, the latest date on which I have a record. In 1890, when I had a seaside garden on the Solway, it was in flower on January 13, the earliest date of which I have any note. In the same garden my latest record was in 1891, when it did not flower until February 28. In an inland garden in later years it did not flower until March 2 (1915), as compared with February 14 two years before. This miniature Daffodil should be grown much more extensively in the rock garden, where it is quite in harmony with the smallest of alpines. But it seems impossible to secure the exceedingly small form of N. minimus we were able to procure on its introduction to cultivation. This was much smaller and neater than the form now obtainable. I believe this Narcissus is very variable in its native habitats, and it is possible that the smaller variety may yet be re-introduced. *S. Arnott.*

Manuring Arable Land.—Although born on a farm, I know little of farming. Horticulture has been my profession, therefore I plead ignorance of the amount of manure it is possible to plough into average farm land. Recently, when discussing the poverty of certain land, I suggested that instead of the usual ten or twelve tons per acre, the dressing should be increased to twenty or twenty-four tons, but was told that it was impossible to plough in such an amount. Gardeners know the value of heavy dressings of farmyard or stable manure to provide humus in the soil, and as very many gardeners have charge of arable land, I would like to know what is the heaviest dressing of manure they have ploughed in. In other words, has any reader ploughed in twenty or twenty-four tons of manure per acre, and if so, what traction was used. This is not an idle question, nor is it one of passing interest; it is a matter of very great importance. *C. de B.*

Glossiness in Flowers.—In his excellent article under the heading of " Ranunculus gramineus " (March 23, p. 220), your correspondent, Mr. J. Parkin, raises an interesting point in his reference to the glossy type of petal found in the majority of the Buttercups, and goes so far as to assert that this characteristic of some of the Ranunculi is " probably unique among flowers." It must, in fairness to Mr. Parkin, be pointed out that he uses the non-committal term " probably," but is so sure of himself as to throw out a challenge to all and sundry to produce a worthy rival. His contention is certainly something of a " poser," and a difficult proposition, for, in my opinion, with only a single exception, one is forced to admit that Mr. Parkin has much to substantiate his claim, and a " clear case " for his champion. A host of subjects occur to the mind, which on first thought might be put forward as having the necessary " glazed " appearance to warrant being considered on a par with the Buttercups; for instance, Lapagerias, Rhododendron Roylei or R. campylocarpum, and, again, some of the deeper shades of single Dahlias, etc., etc.; but on further consideration, could one honestly call any of these glossy? Rather would the term " waxy " be a nearer approach to the correct description. The one exception to which I refer, and in my humble opinion, the only one that is in a position to challenge the supremacy of the Buttercup, is the Oriental Poppy (Papaver orientale), and I bring this lowly—but by no means humble—occupant of the herbaceous border to the notice of Mr. Parkin, and let him judge. I refer, of course, more particularly to the scarlet varieties of the species—such as Lord Lambourne—as I would not go so far as to assert that the white or pink shades possess the same lustrous sheen that the scarlet varieties do, and consequently do not put them forward as rivals to the Buttercup in the distinctive feature of glossiness. It would be interesting to have other readers' views on this highly interesting subject. *T. Wilson, New Barnet.*

What shall we do with our Greenhouses?—Mr. W. F. Baker's admirable and broad view of this subject has earned my gratitude. I am sorry others have not written. The law of supply and demand always controls the particular situation, and an observant man can generally find out what sells best. My main point was to foster the employer's interest in greenhouses, be it scientific, pleasurable, or commercial, and so revive a department that since the war has seemed a " white elephant." *G. H. Emmett, The Gardens, Taplow Court.*

Gardeners' Pay and Agricultural Scholarships.—I have been interested in the discussion on " Gardeners' Pay and Status." There seems to be a concensus of opinion that wages are too low, but that they cannot be forced up. On the whole, the attitude of correspondents impresses me as moderate and wise. There is, however, an angle from which the matter might be considered other than improved education through mutual improvement societies, and that is to lighten the pressure of young labour by finding other outlets for it. It is the fact that very many boys go into gardening because they like it, and although they are dissatisfied later in life, owing to the poor emoluments, they do not find other outlets for their own sons to any particular extent. On the contrary, there is a pronounced movement of gardeners' sons into the profession, and the abundant supply of young gardeners tends to prevent a general rise in wages. This is in accordance with the recognised effect of supply and demand. So far, nobody will disagree with me, but when I proceed to mention agriculture as an alternative, there will be a general gasp of amazement. Nevertheless, I make bold to draw attention to the fact that very attractive scholarships are offered for the sons of working folk (among whom gardeners would be classed officially) in cases where the boys have done at least one year's practical work of certain kinds, which include horticulture. Let us suppose that a gardener's son has left school at fourteen and worked two years in a garden. He has become eligible for a scholarship, tenable at a farm institute, of a very handsome kind. Not only are board residence, tuition fees and laundry covered, but allowances are included to provide for extra clothing, books, games, club subscriptions, etc. At the farm institute he will receive practical instruction in commercial horticulture, such as market gardening and fruit-growing, in addition to dairying, poultry-keeping, and more distinctively agricultural jobs. Surely this is worth considering, yet in some counties, at all events, the response has been very poor indeed. I suggest that gardeners who are dissatisfied with their own rewards, and yet who are in doubt as to what to do with their sons, write to the Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S.W.1 (or alternatively, to their County Agricultural Organiser) for Form A141/TE, and give it careful consideration. It might very well be that a certain number of boys who have had a preliminary horticultural grounding (perhaps in the gardens managed by their fathers, perhaps under other professionals) would prove so apt that they would qualify for higher wages as foremen, or pruners and grafters, in commercial plantations or market gardens. In any case, I can hardly imagine their being anything but better qualified to earn their living for the experience which they had undergone. At the very least they would gain an insight into a wider range of work. As the situation is one for practical suggestions (which it will be agreed are not easily found), I offer this as a modest contribution. *W. P. W.*

The Late Mr. John Cypher.—Everyone will agree with *A. F.* (*The Gardeners' Chronicle* of March 23) that the late Mr. John Cypher's great services to horticulture and to horticultural societies in particular, are worthy of some lasting recognition. As *A. F.* truly states, everyone loved Mr. John Cypher; he was loyal to his friends and always ready to do anyone a good turn, and he endeared himself to a very wide circle of friends by his many acts of kindliness. I personally received much kindness from him in my early days, and little thought then that I should be called upon to judge so many of his wonderful exhibits. It is very pleasing to see his family nobly carrying on the tradition of a famous name, with its long and distinguished record. I am much in favour of the suggestion put forward by Mr. Barnes in your issue of January 5, and feel sure that if exhibitors or some society would take the matter up, there would be no lack of financial support for such a purpose. *F. Jordan.*

THE FUTURE OF THE POTATO.

Mr. W. Cuthbertson discusses, in your issue of March 30, a policy which he recommends should govern the selection of Potato varieties; in particular, he stresses the importance of retaining outstanding seedlings which are susceptible to wart disease. Mr. Cuthbertson has exceptional knowledge of the Potato, and his opinions carry great weight.

Anything which tends to break the rigidity of outlook among our breeders is to be welcomed, and the writer desires to call attention here to some other aspects of the problem. These notes, moreover, are intended to provoke discussion, as the writer has not a wide commercial experience, and may not, therefore, be in possession of all the facts.

Many raisers discard seedlings, not only because they are susceptible to wart disease, but also because they have (1) yellow or pale yellow flesh, and (2) pink or red skin.

Why yellow flesh should be regarded as a merit in many parts of Europe and a fault in others, has always been a mystery to the writer. Yellow flesh is not correlated with any commercial quality, and a yellow-fleshed variety may excel present-day white-fleshed varieties in all directions. The same is true of pink or red tuber skin. The disadvantages of a dark purple skin are obvious, but surely the popularity of Kerr's Pink should be sufficient answer to those who assert that seedlings with pink skins must be discarded. It appears that these two prejudices are founded neither on reason nor experience.

In discussing the future of the Potato, Mr. Cuthbertson rightly keeps in view the question of cooking quality. To the writer, it seems that this question has not always received the attention it deserves, and there is no doubt that investigations on the subject must be made in future. Mealiness and good flavour seem to be essential qualities in this country, but these are not enough; more must be known about feeding values, digestibility, vitamin contents, blackenings, etc.

Do virus diseases account for all the deterioration of Potato stocks, as many authorities state? In the writer's opinion the environment in which the "seed" was grown contributes something at least to the potential yielding capacity, quite apart from its effect on the distribution of virus diseases. This is a matter for future investigation; it is not enough to state that in the absence of virus diseases a certain level of productivity can be maintained; high yields may quite readily be the expression of a favourable seed environment. It is not an uncommon experience to see two stocks of the one variety growing side by side in the same field and exhibiting differences in "vigour" and yield, yet showing no obvious variations in the incidence of virus diseases. Horticulturists sometimes meet what are known as "hide-bound" Potatos which, when planted, produce small plants and small yields, and which generally do not decay before lifting time. This, of course, may represent an extreme condition and be due to faulty storage, yet it is sufficient to indicate that the potential yielding capacity of "seed" does not depend on virus diseases alone when other diseases and injuries are absent. *T. P. McIntosh.*

FRUIT GARDEN.

THE ALPINE STRAWBERRY.

Although this fruit cannot take the place of the well-known garden varieties, it certainly deserves more attention than it obtains. The flavour of a fully ripened fruit is distinct and rich, yet elusive, a flavour one can never have enough of. A search among the foliage will usually be rewarded during the months of July, August and September, even after the first flush of fruits is over. Many connoisseurs consider the fruits are never better than when eaten freshly gathered from the bed. There are also ways of preparing them for the table, especially in Continental cookery.

The best strain I know of is that sent out by Messrs. Sutton and Sons. The plants are vigorous and productive, bearing fruits of rich flavour and nearly twice the size of the ordinary Alpine Strawberry.

Seeds sown in April or May in a cold frame soon germinate, and if the seedlings are transplanted when large enough to handle, they will make good plants by mid-August, when they should be placed in their permanent quarters. A plot from which second early Potatos have been lifted will usually be found in excellent condition for their reception. Plant them in rows two-and-a-half feet apart and allow one-and-a-half foot between the plants. Subsequent culture consists of cutting off all runners, and hoeing sufficiently to keep a good surface tilth between the plants.

Although I have grown these Strawberries for many years, I never remember any plants affected by disease. The fact that they are raised annually or biennially from seeds may account for their immunity; another important factor is that the new bed is usually formed on fresh ground at some distance from the old one.

Provided there is sufficient lime in the soil an artificial manure compounded of 3 lb. of sulphate of ammonia to 12 lb. of superphosphate may be used with advantage at the rate of 4 ozs. per square yard in April. Slugs are a nuisance in moist seasons. Caustic lime applied in the form of fine dust early in the season, when the slugs are feeding, is a remedy free from risk, although bran poisoned with Paris-green is the more deadly.

At flowering time, clean straw should be placed among the plants for the fruits to rest on later. It is rarely necessary to net the bed, as the fruits are generally protected by the foliage. *J. Comber.*

SOCIETIES.

NATIONAL ROSE.

April 19.—The Annual Spring Show of Roses was held at the R.H.S. Hall, Westminster, in warm, sunny, spring weather. The exhibits were fully up to the average in numbers and the quality was very good, although there were fewer new seedlings than at former spring shows, and only one Certificate of Merit was awarded. During the morning, Princess Mary, Viscountess Lascelles, visited the show and expressed great admiration for many of the exhibits. The attendance was not so large as usual.

Certificate of Merit.

Julien Potin.—As shown, this is an exceedingly beautiful Pernetiana Rose, but we suspect that the outer petals fade quickly, and so would detract from the glowing beauty of the flower. The long stems bear the characteristic glossy, deep green leaves of the type. The flowers, which, upon reaching maturity, are large, are very shapely in all stages, and have long calyces which are often distinctly serrated. The petals are broad, stout, and roll attractively. The colour is a rich golden-yellow which glows in the heart of the flower, and there is a slight fragrance. The variety was distributed in France in 1927. Shown by Messrs. G. Beckwith and Son.

Other Novelties.

The best of the other novelties, Polly, shown by Messrs. G. Beckwith And Son, received the Certificate of Merit in 1927, and a good illustration appeared in *The Gardeners' Chronicle* for September 17 of that year. On the present occasion the flowers were especially fragrant. The colour is rather variable, but generally is of salmon-peach shading, with a deep gold base. Florex, also exhibited by Messrs, G. Beckwith and Son, is an American H.T. variety. It is a fully double, globular, deep pink flower and pleasantly fragrant. Daily Sketch, shown by Messrs. B. R. Cant and Sons, lacks form, but the colour is a vivid orange-scarlet.

Groups of Roses.

The only exhibit staged in Class 1, for a circular floor group of Roses, was that by Messrs. Chaplin Bros., Ltd., and this was awarded the first prize. It consisted of a tall mound of standards and climbing sorts, edged with dwarf Polyantha Roses, among which were floriferous specimens of L'Ideal, Golden Salmon, Locarno and Superba. There were well-flowered standards of Golden Emblem, Lady Inchiquin, Gwyneth, W. E. Chaplin and Betty Hulton, while crowning the group were tall weeping standards of Excelsa, White Dorothy Perkins and Lady Godiva.

Mr. Elisha J. Hicks was first of three in the second class, for a group of cut Roses on staging twenty feet by three feet, with a magnificent bank of blooms. The background consisted of sheaves of Climbing Lady Hillingdon, Climbing Mrs. H. Stevens; and Orange King, La Reine Elizabeth, Coral Cluster, Kersbergen, Pride of Hurst and Frank Leddy, good Polyantha Roses; there was an attractive corner pillar of Mrs. H. Stevens, other outstanding sorts being Betty Uprichard, Padre, Cuba, Angele Pernet and Souvenir C. Pernet. Messrs. Benjamin R. Cant and Sons, Ltd., were second with a charming group in which the richly coloured Padre was prominent, together with Mrs. Beatty, Lady Wakefield, Lady Forteviot and Phoebe, while Mr. George Prince was third.

The only exhibit of six pillar Roses was that by Messrs. Chaplin Bros, Ltd., and this was awarded the first prize. It consisted of elegant specimens of Paul's Scarlet Climber, Tausendschon and Dorothy Perkins.

Messrs. Chaplin Bros., Ltd., were also first for a floor group of Polyantha Roses, and deservedly so. They showed a close groundwork of floriferous specimens of White Echo, Locarno, La Reine Elizabeth, Golden Salmon and Superba, and above these were standards of, among others, Scarlet Leader, Ellen Poulsen, Orleans Rose, Alice, Lady Reading and Coral Cluster. Messrs. William Cutbush and Son, Ltd., secured the second prize in this class with a charmingly arranged group, varieties of note being Mrs. A. Hudig, Mary Casant, Kersbergen, Ellen Poulsen, Sunshine and Frank Leddy. The third prize was awarded to Mr. J. H. Pemberton, whose outstanding specimens were of Golden Salmon, Ellen Poulsen, Chatillon Rose and Kersbergen.

The exhibits in the class for twenty-four blooms, in not fewer than eighteen varieties, may hardly be described as of outstanding merit. Messrs. Frank Cant and Co., Ltd., were first, their best blooms being of Holt Hewitt, Lady Inchiquin, Hadley, Sarah Wright and Dorina Neave; the last named was awarded the Silver-gilt Medal for the best Rose exhibited by a nurseryman. The outstanding blooms in Mr. Elisha J. Hicks' second prize collection were of Crusader, Columbia, Mrs. H. Morse and Mrs. H. Bowles, while among those staged by Messrs. Benjamin R. Cant and Sons, Ltd., which were awarded the third prize, the best were Mrs. Walter Jones, Rev. F. Page Roberts and Mildred.

There were only two entrants in Class 6, for twelve blooms of any variety, namely Mr. A. T. Goodwin, who received the first prize for good specimen blooms of Maréchal Neil, and Messrs. Benjamin Cant and Sons, Ltd., whose second prize exhibit was of blooms of Mrs. Beatty.

Mr. Goodwin was the sole exhibitor in the class for two baskets, each of a distinct variety, and he was deservedly awarded the first prize for grand examples of Frau Karl Druschki and Maréchal Neil, while Messrs. Chaplin Bros., Ltd., were awarded the first prizes in Classes 8 and 9, being the only exhibitors in each. In both classes—the former, for one basket of cut Roses, one variety; and the latter for one basket, one or more varieties—they staged charming arrangements of good blooms of Madame Butterfly.

The Class for six new Roses did not produce any special flowers. Mr. Elisha J. Hicks was awarded the first prize.

Amateurs' Classes.

In the chief amateurs' classes the quality of the blooms was very good indeed and, particularly those shown by Mr. G. A. Hammond, many being exceedingly fragrant. Mr. G. A. Hammond, Burgess Hill, was first in the class for a group of Roses on the staging with a handsome arrangement which included superb blooms of Mrs. Foley Hobbs, Gorgeous, Mrs. Henry Morse, Lemon Pillar and Mabel Morse. Mr. H. R. Darlington, Potters Bar, was awarded the second prize. Mr. Hammond was also first in the class for twelve exhibition blooms, where he staged another superb exhibit. He included, in a perfect specimen of Mrs. Campbell Hall, the Silver-gilt Medal bloom of the section, and also had beautiful flowers of Mrs. C. Lamplough, Mrs. E. Mawley and Mrs. Foley Hobbs. Dr. G. E. Dixon, Norwich, was second.

The best six exhibition blooms were shown by Mr. Cuthbert Dixon, High Wycombe, whose finest were of Mrs. G. Marriott, J. G. Glassford and Mrs. C. Lamplough. Mr. J. N. Hart, Potters Bar, was second of the four exhibitors. With an even set of Mrs. Foley Hobbs, Mr. J. N. Hart was first in the class for six of any one variety, and Mr. C. Dixon was second with the same variety. Mr. T. W. Elcock, Carshalton, won the first prize for six blooms in not fewer than three varieties, and Mr. Hart was first with six good vases of any number of varieties. First prizes for baskets of Roses were won by Mr. G. A. Hammond, Mr. H. Oppenheimer, Caterham Valley, and Mr. L. P. Roberts, Dorking.

The Decorative Classes in the two sections were very attractive, although similar varieties were used in a number of instances. In the dinner table classes, Mrs. L. R. May, who used Lady Sylvia, was first in the open classes, and Mrs. Courtney Page was equally successful in the amateurs' class. Mrs. May had the best bowl of Roses in her section, and Mrs. C. Page won the first prize in the amateurs' class, while Mrs. A. D. Ruff had the best vase of cut Roses.

ROYAL HORTICULTURAL.

April 23 and 24.—There was a large and exceedingly interesting show in conjunction with this fortnightly meeting of the R.H.S., which was held in the New Horticultural Hall, Westminster. One of the principal groups was a superb arrangement of Cymbidiums on a large floor space. There were also several particularly good general collections of Orchids in their accustomed place; the Orchid Committee recommended two First Class Certificates and two Awards of Merit to novelties. Exceptionally good plants of Schizanthus, spring-flowering trees and shrubs, alpines, Roses and Carnations were the chief floral features; the Floral Committee recommended seven Awards of Merit to novelties. Narcissi were again staged in great excellence, and there was an admirable group of Tulips; the Committee recommended one Award of Merit to a novelty. There was no new variety before the Fruit and Vegetable Committee, and only one small exhibit in the hall.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mrs. E. Du Pont (a visitor from America), Mr. Lionel de Rothschild, Mr. Fred J. Hanbury, Mr. Fred K. Sander, Mr. S. H. Low, Mr. R. G. Thwaites, Mr. E. R. Ashton, Mr. T. Armstrong, Mr. Charles H. Curtis, Mr. H. H. Smith, Mr. H. G. Alexander, Mr. W. H. Hatcher, Mr. A. Dye, Mr. J. E. Shill and Mr. J. C. Cowan.

First Class Certificates.

Miltonia William Pitt, Baron Schröder's var.—A gloriously coloured form, with sepals and petals of bright, glowing crimson, and a broad, deep, rose-red, crimson-tinted, blush-margined lip. The mask is white with a few red lines, and the disk is yellow. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Brasso-Cattleya Springtide, Stonehurst var. (*B.-C. Maroniae × Cattleya Mossiae*).—A very fine, large-flowered variety of deep rose-purple colouring and a dull gold area over the centre of the fringed lip. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Awards of Merit.

Odontioda Gwentara (*O. Alcantara × O. Gwendoline*).—In this handsome hybrid the colour is rich cardinal-red with an irregular edging of rose-pink; the lip has a wider rose-pink margin than the sepals and petals. Shown by Messrs. Charlesworth and Co.

Odontioda Marie Antoinette var. excelsa (*Oda. Colinge × Odm. President Poincaré*).—A very pretty and shapely flower with irregular red markings surrounded by blush lines; the margins are rose-coloured and the lip is pink, with a deep red blotch below the golden disk. Shown by Messrs. Charlesworth and Co.

Cultural Commendation.

To Robert Paterson, Esq. (gr. Mr Merry), for Miltonia Phalaenopsis, with fifteen flowers.

Groups.

Messrs. Sanders excelled themselves on this occasion, as they not only occupied their usual position near the dais, but had a big circular group in front of the dais. This was a superb exhibit consisting of twenty large specimen Cymbidiums, each carrying from four to a dozen big spikes of attractive flowers. These fine plants were given ample space on a ground work of moss, mounded towards the centre. The leading varieties were C. Ceres, C. Pauwelsii and C. brugense, and the total number of spikes was one-hundred-and-seventy. In their other group, the St. Albans firm displayed Dendrobium thyrsiflorum, Angraecum sesquipedale, Ansellia africana, Coelogyne Mooreana, Zygopetalum Perrenoudii, Dendrobium Wardianum, D. Dalhousieanum, Odontioda Bradshawiae, Bifrenaria pubigera, B. Harrisoniae, with Lycastes and Masdevallias.

Messrs. J. and A. McBean had a very bright group in which the hybrid Oncidium McBeanianum was conspicuous, but Odontoglossums were the leading feature, and these included O. loochristiense, O. Phoebe, O. crispum in variety, O. percultum, O. Thompsonianum, O. Pyramus and the handsome O. Queen Alexandra. Miltonia Phalaenopsis, Epiphronitis Veitchii and Cymbidium Devonianum were also included.

In Messrs. Stuart Low and Co.'s group, we noted Dendrobium thyrsiflorum in fine form, Cypripedium Massaianum, Cattleya Skinneri alba, Cypripedium niveum, C. Charles Richman, Laelio-Cattleya Wellesleyae, and Oncidium leucochilum. A fine example of Cymbidium Devonianum with five spikes was shown by Mr. J. Evans.

A glorious group of Orchids was submitted by Messrs. Charlesworth and Co., who arranged their plants in a setting of Ferns and moss. The principal subjects were Odontoglossums and Odontiodas. The latter included O. Charlesworthii, O. Nagara, very bright; O. Victoria, O. Eulalia, O. Beacon, O. Aricia and O. Navette. The leading Odontoglossums were O. crispum, O. Omega, O. Toreador, O. Llewellyn, O. Epicasta, O. Victoria and O. Decius. Other fine things on view included Dendrobium Brymerianum, D. infundibulum, Miltonia Lycaena, Vuylstekeara Rudra, Oncidium papilio var. majus and Epidendrum Endresii-Wallisii.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. James B. Riding, Mr. C. F. Langdon, Mr. Donald Allan, Mr. M. C. Allwood, Mr. D. Ingamells, Mr. William Howe, Mr. W. B. Gingell, Mr. R. Findlay, Mr. D. B. Crane, Mrs. Helen Lindsay-Smith, Mr. Charles E. Pearson, Rev. Rollo Meyer, Mr. E. R. Janes, Mr. Arthur Turner and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. W. J. Bean, Mr. G. Reuthe, Mr. F. G. Preston, Mr. Eric M. Marsden-Jones, Mr. A. Bedford, Mr. L. R. Russell, Mr. T. Hay, Mr. A. Williams, Mr. G. Yeld, Mr. R. C. Notcutt, Mr. W. B. Cranfield, Sir William Lawrence, Bt., Mr. James Hudson, Mr. E. A. Bowles, Mr. T. W. Taylor, and Mr. Amos Perry, with the Marquess of Hartington and Mr. J. G. Millais, visitors, and Mr. N. K. Gould, Secretary.

Awards of Merit.

Astragalus utahensis.—This is a very attractive little Milk Vetch. It is a compact plant bearing silvery stems and leaves, and spikes of rose-purple flowers. Shown by Charles T. Musgrave, Esq., Hascombe Place, Godalming.

Anemone St. Brigid, Mary Seton.—A very handsome variety. The large, well-rounded flowers are substantial in texture, and glowing rose-cerise in colour, with a definite paper-white zone. Shown by Mrs. M. B. Henderson, (gr. Mr. W. J. Symons), Marlborough, Falmouth.

Dianthus Allwoodii var. Prudence.—The flowers of this variety are decidedly larger than usual. The colour is pale pink and the award was given for the variety's value as a cut flower. Shown by Messrs. Allwood Bros.

Hippeastrum Lady Juliet Duff.—This is a gorgeous variety. The flowers are large, round and of rich, glossy crimson colour. Shown by Lady Juliet Duff (gr. Mr. H. Weaver), Coombe Court, Kingston Hill, Surrey.

Omphalogramma sp. K.W. 6,821.—This is a very uncommon and beautiful little plant. The flower, which is produced in advance of the foliage, is only a few inches in height, and has much the general appearance of a single bloom of an unusually large Streptocarpus. The colour is bright blue, and there are creamy-white markings in the tube. The slender, pale green stalk is covered with fine hairs. Shown by Sir John Ramsden, Bart., Bulstrode, Bucks.

Mertensia moltkioides.—This species, which is from the Himalayas, is distinct from most of the genus. It is a compact, free-flowering little plant which, at first sight, suggests an unusually sturdy Forget-me-not. It has small, linear leaves and clusters of blue flowers. Shown by Mr. T. Hay, Hyde Park, London.

Rhododendron charitopes (?), *Forrest* 25,570.—A pretty little evergreen species of erect habit which flowers when quite dwarf. The small, obovate leaves are green above and pale below. The somewhat long-stemmed flowers, which are in loose trusses, are widely expanded, pink, flushed with a few carmine spots; the anthers are erect, but the stigmas incline outwards at a sharp angle. Shown by Lady Aberconway and the Hon. H. D. McLaren (gr. Mr. F. C. Puddle), Bodnant, North Wales.

Cultural Commendation.

A card of Cultural Commendation was awarded to the Director, Botanic Gardens, Cambridge, for particularly good flowers of Rosa gigantea.

Groups.

A very handsome group of Schizanthus hybrids was exhibited by Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore. The exceptionally well-grown plants were in relatively small pots, and the shapely plants bore quantities of large flowers of many beautiful colours. The Studley Horticultural College for Women had a good group of Schizanthus and Stocks, and Messrs. Dobbie and Co. staged particularly good cut stems of Schizanthus. Among the Orchid collections, Messrs. Stuart Low and Co. grouped Acacias, Camellias, Hippeastrums and Genistas.

Flowering shrubs of great beauty were shown by Messrs. Hillier and Sons, Mr. H. Hemsley, Messrs. J. Cheal and Sons, and the Lye Green Nurseries. There were many collections of alpines and the chief exhibitors were C. Kirch, Esq., Edenhall, Beckenham, who included Daphne petraea, Androsaces, Ranunculus crenatus and Auriculas. Mr. Clarence Elliott, Messrs. Casburn and Welch, Messrs. W. H. Rogers and Son, Messrs. Bakers, Mr. Stephen Sims, Messrs. Hollambys, Mr. George E. P. Wood, Mr. W. E. Th. Ingwersen, Mr. E. Ballard, Messrs. Waterer, Sons and Crisp, Messrs. Tucker, Messrs, Maxwell and Beale and Messrs. Prichard and Sons.

Attractive collections of Roses were set up by Messrs. B. R. Cant and Sons, Messrs. F. Cant and Co., Messrs. W. H. Cutbush and Son, and Mr. J. H. Pemberton. Their usual good collections of Carnations were staged by Messrs. Allwood Brothers., Messrs. C. Engelmann, Ltd., and Messrs. Stuart Low and Co. Fanny, Lady Leon (gr. Mr. W. Sorrell), Bletchley Park, Bletchley, displayed many well-grown plants of Cineraria stellata. Messrs. L. R. Russell, Ltd., had a small group of stove plants. Mr. G. H. Dalrymple showed coloured Freesias and Primula pulverulenta. Mr. Charles Hall staged examples of a good strain of long-spurred Aquilegias. Mr. Baldwin Pinney showed Violets, and good Anemones were exhibited by Messrs. Reamsbottom and Co., and by Mrs. Bucknall.

Narcissus and Tulip Committee.

Present.—Mr. E. A. Bowles (in the chair), Mr. Peter R. Barr, Mr. W. B. Cranfield, Mrs. Brodie of Brodie, Mr. L. J. Richardson, Mr. F. Herbert Chapman, Miss E. Willmott, Mr. J. D. Pearson, Mr. Alfred White, Mr. F. A. Secrett, Rev. Rollo Meyer, Mr. Charles H. Curtis, Mr. W. Poupart and Mr. A. Simmonds, Secretary.

Award of Merit.

Narcissus Sunstar.—This is a Barrii bicolor variety of charming form, with firm textured, broad, creamy-white segments which are waved and slightly incurved on the margins. The flattened, frilled corona is rich orange-red, shading to pale orange at the base. The flowers are borne gracefully on rather slender, tall stems, and the narrow foliage is rich, dull green. Shown by Mr. L. J. Richardson, Waterford, as a show flower.

Groups.

One of the most striking displays in the hall was the magnificent ground group of Tulips, in the form of two mounds forming a huge oval bed, arranged by Messrs. Sutton and Sons. It occupied a large portion of the floor space in the centre of the hall, and each plant, bedded in moss, was a grand specimen. Crowning the mounds were masses of the deep scarlet City of Haarlem, and the glowing deep rose King George V. The arrangement of the various colours was very fine, for such varieties as · Solfaterre, primrose-yellow; Prince of Orange, copper; Victory, crimson-red; Zwanenburg, pure white; Edmée, deep rose, shading paler; W. A. Veruly Nerbrugge, bright red; Rev. H. Ewbank, smoky pale mauve; Inglescombe Yellow; and the golden Bouton d'Or, blended or contrasted tastefully, other grand sorts being Louis XIV, Brederode, Afterglow, Ronald Gunn, Bacchus, Mrs. Moon, Antony Roozen, and the fimbriated Sundew.

Narcissi were fairly prominent at this meeting. Messrs. Barr and Sons, Ltd., had a tastefully arranged display, which included grand blooms of Beersheba, Empire, Adventure, Polemon, Carmenta, Susette and several choice seedlings under numbers; while Messrs. J. R. Pearson and Sons had grand examples of Tresserve, Nevis, Purity Maiden, Beersheba, Orange Glow, Havelock, Fortune, Tenedos, Kelligrew, Van Waveren's Giant, and others, in their charming exhibit.

Thomas Hay, Advance Guard, Empire, Mary Rose, John Evelyn, Mozart and Kantara, were striking sorts in the display set up by Messrs. R. H. Bath, Ltd.; Messrs. G. W. Miller used choice Narcissi in variety as a background to Primroses, Polyanthuses, Saxifrages and Daisies in variety; while outstanding sorts in Messrs. J. W. Barr's group were Croesus, Danesfield, Madame du Barri, Patricia, Jocelyn and Queen of Beauty.

Among the many grand varieties displayed by Messrs. Herbert Chapman, Ltd., we noticed exceedingly fine blooms of Callirhoe, Chiltern, Marmora, Yukon, Holmdale, Henry Burra and Halfa. A bright golden, unnamed Trumpet variety attracted attention, while also included in this exhibit were several numbered seedlings of grand form and colouring.

Messrs. D. Stewart and Son had a decorative collection which embraced many popular sorts, while Mr. Herbert G. Longford staged a mixed collection of Narcissi and Tulips.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. C. G. A. Nix, Mr. G. Beckett, Mr. A. Bullock, Mr. W. F. Giles, Mr. F. Jordan, Mr. H. Prince, Mr. F. Bostock, Mr. A. Poupart, Mr. G. F. Tinley, Mr. W. H. Divers, Mr. W. Poupart and Mr. A. N. Rawes, Secretary.

Other than the small exhibit of Apples by Messrs. J. Cheal and Sons, Ltd., this Committee had nothing to consider.

Groups.

The Apples exhibited by Messrs. J. Cheal and Sons, Ltd., were in excellent condition for so late in the season, and included good examples of Wagener, Prince Albert, Ontaria, Dumelow's Seedling, Encore, Crawley Reinette and Beauty of Kent.

INSTOW SPRING FLOWER SHOW.

This show was held on the day originally fixed, as the unusual warmth from March 25 onward brought on everything with a rush, and by early April had converted a season which at the beginning of March was a month late, to an almost normal one.

Each year proves more conclusively the soundness of the idea of a show without prizes, and that, owing to a very broadly drawn schedule and everything being entered in groups, the very best flowers can be produced, and artistically a much better display can be made, than when exhibitors are tied to only three or six blooms of a sort, as must be the case when there is judging on the usual lines.

The show was the eighth of the series, and the very best of all.

Cut Daffodils.—A forty-five feet run of closely packed, three-tier staging held three large and four small groups. The Bulb Farm (Mr. Cobley and Mrs. Snell), Miss Hinchliff and Messrs. Barr and Sons had each about fifty to fifty-five varieties of Daffodils, and the four smaller groups of six to twenty-one—these coming from the Rev. T. Buncombe, Mrs. J. Pike, Mrs. Hinchliff and Mrs. Carbonell.

The Bulb Farm had a magnificent display from a bunch of Fortune downwards, their flowers including Robespierre, Greysteel, Queen of Hearts, Magnolia, Nimrod, Pedro, Harvester, Amber, Heron, Tunis, numbered seedlings, and a wealth of others—a real treat to contemplate.

Miss Hinchliff had Beersheba, Eve, Elinore, Burgomaster Max, Goldbeater, The Perfect Gentleman, Golden King, two good seedlings, Gwendal, Pilgrimage, Golden Pedestal, H. C. Bowles, Elfreda Pearson, Croesus, Donax, Buttercup and two early Poets.

Messrs. Barr and Sons' outstanding feature was two large bunches of unusually fine flowers of Sunrise, associated with John Evelyn, Red Beacon, Tasse d'Or and a host of other good things.

The Rev. T. Buncombe showed Cicely, Eve, etc., but his garden is too high for an early show in a late season.

Greenhouse Groups.—There were five large groups, all good, notwithstanding that many exhibitors had great difficulty in keeping the frost out of their houses in February. Mrs. Lane included some good Pelargoniums; Miss Hinchliff some terra-cotta, brick-red, and blue Cinerarias; Mrs. Hinchliff some very fine Primula obconica, Asparagus and Cinerarias; Mrs. Evatt and Mrs. Critchley showed Azaleas, Primula obconica, etc., and all had some Arums (Richardias) for background.

Bulbs in fibre produced some good Daffodils, Tulips and Hyacinths, particularly those from Mrs. Lane. Flowering shrubs included about ten kinds, shown by Miss White-Atkins and Miss Hinchliff; these included Skimmias, white Ribes, Jews Mallow, Mahonia, Almond, etc.

Primroses were represented by florists' varieties, blue, red, yellow, white, etc., and Hose-in-hose, but the gem was Miss White Atkins seedling form of P. Juliae.

The following plants, among others, were shown:—Iris bucharica, Anemone Pulsatilla, A. ranunculoides, A. coronaria and A. fulgens; Hellebores (varieties of orientalis), blue Hyacinths and Chionodoxa, Triteleia, Grape Hyacinths and Tulips.

Only four sorts of Apples were shown—Blenheim Pippin, Bramley's Seedling, Annie Elizabeth and Newton Wonder.

GLASGOW AND WEST OF SCOTLAND.

Mr. Isaac Fleming, Paisley, presided at the monthly meeting of the Glasgow and West of Scotland Horticultural Society on April 10, when a paper on "Roses" was read by Mr. Tom Baxter, of Messrs. Thomas Smith and Sons, Stranraer.

He dealt chiefly with the merits of the various stocks, and in discussing Rosa canina, which is used universally, he said the reason for its supremacy over all the others was its adaptability to every type of soil and, no matter to what class they belonged, all cultivated Roses thrived on that stock, whether it was used in the seedling or cutting form. The chief points advanced in favour of the Briar as the best stock for Roses were: (1) its fibrous and deep rooting system; (2) its power of imparting to the garden Rose just the right amount of extra vigour required to produce good flowers; and (3) its proved ability to sustain plants over a great number of years.

Commenting on the R. laxa stock, Mr. Baxter admitted that it had good qualities, but very bad faults as well. The roots were described as too strong and coarse and badly lacking in fibre. If a maiden plant on R. laxa stock was compared with one on R. canina, it would be found that the former had a lot of long tap-roots, devoid of the small fibrous feeding roots, while the first thing to be noted in the latter plant was the abundance of fibrous rootlets. He further maintained that Rose trees on R. laxa stocks did not suit all soils when transplanted, and that nearly every exhibitor stipulated that his trees were to be on R. canina stock. R. laxa produced an imposing bush, but it soon lost vigour owing to the lack of fibrous roots. One thing in its favour was that it was easily budded and therefore did not call for the same amount of skill on the part of the propagator.

Mr. Baxter predicted a great future for the Kokulinsky Briar, which combined the good qualities of R. canina and R. laxa.

In the course of the discussion which followed Mr. John Bell pointed out that there were several beautiful parks in Glasgow in which Roses could be grown, but there was not a decent Rose garden in one of them. It was a disgrace that the citizens of Glasgow had to go to Edinburgh to see a Rose garden. Glasgow was the wealthiest city in Scotland and could well afford a Rose garden,—yet the Parks Department did practically nothing in the matter! He suggested that the Society should approach the Corporation on the subject. Sir John Reid said he was glad that Mr. Bell had raised the question, for it had often occurred to him that the most was not made of the public parks in Glasgow.

DEESIDE (ABERDEENSHIRE) FIELD CLUB.

The remarkable progress made by this Club was revealed at the Annual Meeting, held at Blanchory (near Aberdeen) on April 13, and presided over by the Marquis of Aberdeen and Temair. The Secretary, reviewing the work of the Club during 1928, said that six excursions had been held, and during one of them they opened new ground for the first time in their history; they visited that part of the Mearns district that lay beyond the Mount, which is outside the Deeside Valley. This innovation was heartily approved. The membership is still maintained at the limit, with a waiting list of some thirty or forty, and comprises twenty-three honorary members, thirty life members, and 432 ordinary members. The Treasurer, in his report, said they started 1928 with a balance of £91 10s. 0d.: the members' subscriptions, amounting to £119 18s. 0d., were the highest ever paid. The year closed with a balance in hand of £124 4s. 9d., which was considered highly satisfactory. Warm tribute was paid to the Club's publication, the *Deeside Field*, the Secretary stating that from the beginning, to the present time, the total receipts for the four numbers were £1,000. Arrangements were made for a fifth number to be published at the end of 1930. Lord Aberdeen suggested that the unwearying services of Mr. Bentley Philip, the Secretary of the Club and Editor of the *Deeside Field*, should be publicly recognised by the presentation of some gift. This was warmly agreed to.

Dr. Bremner, Aberdeen, reporting on the work of the Club's photographic survey of the valley of the Dee, said it was developing along well directed lines. The enlarged photographs displayed of Deeside vegetation and scenery illustrated the progress made by the survey.

Dr. Douglas Simpson, Librarian of Aberdeen University, reported that the ruins of Kindrochit Castle, supposed to be the oldest in Scotland, had now been placed in a reasonably sound condition, after much excavation work. The office-bearers were re-elected.

ROYAL CALEDONIAN HORTICULTURAL.

"Spraying for Insect Pests and Fungus Diseases" formed the subject of a paper written by Mr. Charles Webster, Gordon Castle Gardens, and read in his absence by Mr. Ames, of the North of Scotland Agricultural College, Aberdeen, at a meeting of the above Society held at Edinburgh quite recently, under the presidency of Mr. J. T. Jeffrey.

The spraying of fruit trees for insect pests and fungus diseases, Mr. Webster stated, is now looked upon as part of the general routine of garden work, and although great strides have been made in recent years with the treatment for their control, the opinion was general that plant pests and diseases are still on the increase.

Some seasons, no doubt, favoured the increase of certain insects more than others, and the same applied to fungus diseases, but no matter what the season might be, wet or dry, it was certain to be favourable to the spread of some of these troubles. To the gardener it was becoming a serious problem to carry out the work of spraying the trees and bushes at the proper time and, if one had to wait for calm and suitable weather, it was doubtful if all the spraying would be done in season. Whatever type of machine was used, it was important that it should be powerful enough to force the spray to all parts of the tree and to reach the tops of the highest garden walls.

Discussing the treatment of individual fruits, the writer suggested that the winter washing of Apricots should start about the end of October, when the leaves begin to show signs of ripening. Of the various insects attacking Apricots, brown scale is the worst, and where the trees were badly infested, it repaid the labour to have them unfastened from the walls and hand-washed, rubbing the shoots between finger and thumb, as spraying in such cases had no deadly effect. At the same time, opportunity should be taken to spray the crevices in the wall with a strong solution of lime-sulphur. The fruit buds of Apricots, Peaches and Plums are more tender than those of most fruits, and spraying in springtime should therefore be done before any signs of growth are apparent. If spraying has to be done late, "Orchard Spray Fluid" is preferable to lime-sulphur or tar distillates.

Outside-grown Peaches are subject to nearly all the worst insect and fungus troubles which fruit growers have to contend with, and it is doubtful if the crop is worth the labour bestowed on it. Their place might be more profitably taken by other fruits which would give a better return. Winter spraying, no doubt, assisted in keeping the insects in check, but never cleared them out entirely. By spraying again just before the blossom opens with quassia extract or "Orchard Spray Fluid," and again so soon as the fruits have set, the aphis may be got rid of for the rest of the season. To keep red spider in check the trees require syringing with tepid water both morning and evening for a week or more. Leaf blister is not easily controlled, but if the trees are sprayed with Medila before they come into flower, it acts as a check; picking off the affected leaves will also prevent this disease spreading.

Of all hardy fruits which suffer from insects and diseases of one sort or another, the Apple has more than its share. Among the worst of the insects to get rid of is the woolly aphis, and when once established on old trees it would be more profitable to destroy the trees and replant with clean, healthy stock. Capsid bug is another insect which causes a lot of trouble in some districts. It attacks both the fruits and the young, vigorous shoots, completely paralysing all growth for a season and rendering the crop worthless. Spraying with lime-sulphur or tar-mixtures during the dormant season is beneficial, but no matter how carefully the work is done, there are always plenty of bugs left to breed again. Another spraying in April with "Orchard Spray Fluid," just before the buds open, is recommended, as by that time the bugs, so well as other pests—codlin and tortrix moths—will have hatched out and are more easily got at. Spraying with Bordeaux mixture for black scab, so soon as the fruits are set, assists in securing a cleaner crop, but this spray should not be applied in too concentrated a form, as it may cause a big proportion of the fruits to drop, and leave a rusty appearance on the remainder. As Bordeaux mixture and lime-sulphur have had no effect on checking leaf scorch, which seems to have spread during recent years, top-dressing with sulphate of potash is now being tried.

Nearly all varieties of Apple are subject to canker, especially James Grieve and Warner's King. By cutting away the affected parts and painting over the wound with a mixture of tar and clay (one part tar to four parts clay, mixed with water to the consistency of paint) it should heal over, but the trouble usually breaks out in some other part of the tree. Canker is most prevalent on damp, heavy soils, which suggests that imperfectly ripened wood is partly the cause of the disease, as it is seldom found on wall or pot trees, where the growths have a better chance of maturing.

The Apple fruit miner appeared suddenly in July, 1926, and caused serious havoc in gardens along the Moray Firth coast. It was almost impossible to find a sound Apple, and it was certainly the most serious insect pest of that season. There has been no further outbreak and the pest seems to have disappeared as mysteriously as it came.

Green aphis favours the Plum, and black Aphis the Cherry. At the first appearance of either, the trees should be sprayed with quassia or Katakilla. Spraying has not much effect upon brown rot or wither tip fungus, and the best way to prevent it spreading is to cut out all the affected shoots and burn them. Only by hand washing can mussel scale be kept under control. Silver-leaf fungus has not yet reached the Plum trees at Gordon Castle.

Bordeaux mixture assists in keeping scab on Pear trees in check, and lime-sulphur applied before the buds come into flower, combined with picking-off the badly affected leaves, keeps down blister mite. Scraping the surface soil from the bottom of the wall and around the stem, and giving a dressing of two ounces sulphate of potash to the square yard, is also helpful. It is different with the Pear sucker, undoubtedly the worst of the pests which trouble this fruit. If it does not receive necessary attention at the proper time the leaves drop prematurely, weakening the fruit buds for another season and also checking the swelling of the fruits. Fortunately, it is not difficult to keep under, provided the trees are sprayed with quassia or "Orchard Spray Fluid." Should the season be hot and dry, a second spraying may be required about the end of July.

Black Currant mite can be partially checked by using lime-sulphur just as the buds are bursting into leaf; and by repeating the application three times at weekly intervals, the mites can be kept from spreading. Where reversion or Nettle-leaf makes its appearance, the bushes should be destroyed.

Of the different sprays used to check Gooseberry mildew, a solution composed of 1 lb. washing soda and two ounces of soft soap to four gallons of water gives the most successful results. By shortening the young shoots so soon as the mildew makes its appearance, and spraying with soda mixture, repeating the operation in ten days, the bushes may be kept clear of this disease.

The Strawberry is causing considerable trouble at the present time. At Gordon Castle, fresh ground, which had not been in cultivation for fifty years, was tried. Clean, healthy stocks were planted, yet, in the course of four years, the plants went off in the same way as previously.

Of late years there seems to be something wrong with certain varieties of Raspberries. Superlative, Pyne's Royal and Devon, which grew freely at one time, were now dying out. Specimens of Lloyd George growing alongside these other sorts show no signs of weakness, although all are treated alike.

A long and interesting discussion followed, many members giving their views and experiences in the control of the numerous pests and diseases.

Mr. Chisholm, of the College of Agriculture, Edinburgh, referring to the capsid bug, stated that so far no reports of its presence had been received from the twelve counties comprising the south-east district of Scotland, but most of the pests mentioned by Mr. Webster were to be met with all over the country. He emphasised the value of the soda formula for American Gooseberry mildew, and gave it as his opinion that if the bushes were sprayed in the middle of May, and again in the first week of June, a clean crop would be obtained that season. A lime-sulphur spray in spring might not eliminate big bud on Black Currant bushes, but that treatment could control the pest and would enable gardeners to grow a good crop of fruits every year. Absence of potash in the soil produced a weak type of foliage and soft, poorly-ripened wood, which rendered fruit trees liable to leaf-scorch. He believed in building up the constitution of the trees by proper feeding, and planting suitable varieties that offered resistance to the disease. Spraying was excellent up to a point, but it was not sufficient in itself if manuring was defective. Silver-leaf was a scheduled disease and, as spraying had little effect, the best plan was to dig up the affected trees and burn them. If only a branch was affected it should be cut off to prevent the disease from spreading, and he advised that no dead branches should be allowed to remain in the orchard, and thus afford fruiting ground for the fungus.

Mr. J. H. Alexander remarked that the audience was not to infer from Mr. Webster's paper that he experienced a great amount of disease and got very little fruits; the conditions at Gordon Castle were the reverse. On the motion of Mr. William Cuthbertson, a vote of thanks was accorded to Mr. Webster.

Obituary.

William John Jefferies.—Another of the older generation of nurserymen has passed away in the person of Mr. W. J. Jefferies, head of the firm of Messrs. John Jefferies and Son, Ltd., Cirencester. The deceased gentleman had a thorough knowledge of the business he conducted so ably and extended considerably. He was better known personally to the older gardeners and members of the trade than to the present generation, and in former years he was a regular attendant at the meetings of the Royal Horticultural Society, the National Rose Society, and the Horticultural Club. Forest and ornamental trees and Roses greatly interested him and received his personal attention for many years. His activity was amazing, and until the weight of advancing years pressed heavily upon him, he visited every part of the nurseries almost daily, formerly on horseback, latterly in a motor-car. Mr. W. J. Jefferies was highly respected for his personal qualities and his business ability, and for one period he was President of the Horticultural Trades Association. He passed away at Cirencester on Sunday, April 14, having reached the advanced age of eighty-five years. The business will be continued by Mr. E. A. Jefferies, a nephew, who has been associated for many years with his uncle in its management. A portrait and appreciation of Mr. W. J. Jefferies appeared in *The Gardeners' Chronicle* of October 10, 1925.

ANSWERS TO CORRESPONDENTS.

Peach Leaves Unhealthy. — *W. H.* No fungus was found on the Peach leaves sent for examination, and we have come to the conclusion it is a complaint commonly known as "the yellows." Excesses of cold or moisture, either in the earth or in the air, are the most common causes of this condition. Over-deep planting, unsuitable stocks, a sudden spell of very hot weather after a season of cold, may also result in the trouble. The first sign of its presence is a diminution in the green colouring of the leaves, and later a more or less premature ripening of the fruits. Trees on Plum stocks are less liable to attack than those worked on the Peach stock. Is there plenty of lime in the soil? Give a dressing of chalk to the border next autumn, 3 lbs. to the square yard, broken up into small pieces. Another remedy which may be tried now is to remove a little of the surface soil, and dissolve ¾-lb. of sulphate of iron in water, and apply at the rate of ¼ oz. to five pints of water. See that the roots of the tree are fairly moist before applying this, and wash it well in with clear water.

Names of Plants.—*W. C.* 1, Acacia armata; 2, Cupressus thuyoides.

COLOURED SUPPLEMENT PLATE.

Rhododendron campylocarpum.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 51·0°.

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, May 1, 10 a.m. (Greenwich time). Bar. 29·9. Temp. 46° Weather, Overcast.

The Aftermath of Winter.

THE past winter—if past it yet be—gathered into its frigid bosom an ample harvest of garden plants. It exhibited rigour and caprice with evenhandedness. "Whom it would it slew, and whom it would it kept alive." Of plants of the same species and age growing side by side, one was taken and the other left. Thus, with Senecio Greyii, of which many specimens grow and flourish in the garden in which these observations are made, one well-grown plant, planted in a pocket in a wall, is shrivelled, discoloured, and apparently lifeless, and its fellow a yard away, which never grew so well and lagged a long way behind, is unscathed. Near-by are two large specimens of Olearia macrodonta, one stands on ground a few feet higher than that on which the other is planted. The lower plant is seared and unsightly, the higher spruce and fresh as though no winter had assailed it. Cistuses have suffered in like sporadic manner. On a bank facing southward, C. corbariensis and C. crispus are untouched, but in another part of the garden, with fuller exposure to the sun, both have been badly "burned" by the frost. The hybrid Cistus Silver Pink is, or seems, dead. C. ladaniferus is unharmed, but C. villosus, which looks a hardy thing, has not come off scot free. Muehlenbeckia complexa, certified as hardy by Nicholson, may presently show some sign of life, but up till now it looks as dead as dead can be. Lonicera nitida, of which this garden grows long hedges, has not been touched by winter; and all but untouched is along, double hedge of the Jerusalem Sage (Phlomis fructicosa), that wide-spreading, straggly, but strangely attractive plant. It was Mr. Baker, Superintendent of the Botanic Gardens, Oxford, who suggested that we should try this subject as a hedge plant. Greatly daring, we did, and this winter has proved that it will do. Yet, although the plants of the hedge are well enough, a single specimen sheltered by the house, but in a draughty corner, has gone completely black. It will get grey again, no doubt, but the wind has hurt it sorely, Photinia arbutifolia, Bupleurum fructicosum, and Garrya elliptica, have all suffered, albeit the two former much less severely than the last-named. The swift destruction that an ill-timed frost may exercise was well shown by Rhododendron praecox. Never had it flowered better or later. The severe April frost changed in a night the glowing pink or mauvish-pink blooms to a brown, soggy mass. Yet close by, Magnolia stellata had its already open flowers but lightly browned, and its buds uninjured, so that next day the bush was arrayed in pure white again. Desfontainea Hookerii, a little specimen, has remained unharmed. Of groundlings and rock plants we will write but little, although it is worth mentioning that, whereas a good many Primulas seem to have suffered, P. marginata on an exposed bank, if judged by its bright and prosperous aspect, must have enjoyed the winter. The cold and wind played strange tricks with spring flowers. Prunus Davidiana blossomed nearly two months behind its time and then perfunctorily; P. Pissardii, a planted walk of which is the spring glory of this garden, struggled through a slight and belated flowering while its leaves were opening out. Plums, either from frost or last year's heaviness of crop, are no less penurious of flower. The same sharp April frost which destroyed the beauty of Rhododendron praecox arrested the Pear bloom in the bud stage so effectively that it is at least doubtful whether the buds will ever open; yet the buds on the Apple trees, less advanced and hardier, suffered not at all. Spartium junceum has its spiky shoots all turned straw colour. Cytisus scoparius var. Andreanus, hardy enough, looks all black, but C. Dallimorei, old and gnarled, seems very happy and will, no doubt, go on as it has for many years now, flowering profusely and growing scarcely at all. Berberises look generally very bedraggled, B. canadensis worst of all, and B. Wilsonae the least. Rarely, if ever, have gardens shown such a dishevelled appearance as after this late winter, but although spring tarries, plants cannot help but come out like heralds to welcome it. Gradually a welcome greenness steals over the garden, obliterating at least the sharp severity of the losses which it and we have sustained. But although the garden has suffered, the soil has benefited by the severe winter. Ground of heavy nature dug in autumn is now pulverised, and in the lower part of the garden here described the subsoil clay for three spits down, brought up last July to the surface in the form of great, greasy clods, is now fined down to a perfect tilth good enough for the growing of Onions. Two feet down, where the spade reached, may be seen the fissures and fragmentation due to the penetrating frost. If rain comes before it is too late to be of real value, we should have a great garden summer.

Our Supplement Plate.—As our Supplement Plate to this issue we have pleasure in presenting a coloured illustration of the beautiful Rhododendron campylocarpum. Although not new to cultivation—it was introduced into this country from the Himalayas in 1851—R. campylocarpum is by no means common in gardens, chiefly because it is only in the warmest parts of the country that it can be grown with any real prospect of longevity, although it is reported to have survived in the Rhododendron Dell at Kew for twenty years. It is evergreen, and may be regarded as the best of the yellow-flowered species. In height it will attain from six to ten feet, while its flowers, with bell-shaped corollas nearly three inches across, are fragrant, and borne in loose, terminal clusters of six to eight.

Award to the R.H.S. New Hall.—We learn that the medal given annually by the Royal Institute of British Architects for a building completed within the County of London during the last three years, has been awarded to the Royal Horticultural Society's New Hall, the architects of which were Messrs. J. Murray Easton and Howard Robertson.

The Work of the Royal Botanic Gardens, Kew, during 1928.—Those who are interested in the development of the Royal Botanic Gardens, Kew, will read with pleasure the recently issued Appendix I, 1929, of the Kew *Bulletin of Miscellaneous Information*, which contains a review of the work of the Gardens during 1928. An account of the tour by Dr. Hill, the Director, in Australia and Tasmania, Malaya and Ceylon, also of his visit to Java and the Botanic Gardens, Buitenzorg, are given, and there are also short reports of missions undertaken by other members of the Kew staff during 1928. Last year, 1,127,003 persons visited the Gardens, an increase of 48,915 on the figures of the preceding year. In May, the attendance numbered 229,210, the highest monthly total for the year: the lowest was in December, with 6,564. The highest daily attendance was on Whit Monday, May 28, when there were 53,661 visitors, while the lowest was seven, on December 18. The work of the various departments is recorded, together with the developments and plant losses that have taken place. Among interesting plants which flowered at Kew during 1928 are Luculia Pinciana, in the Mexican section of the Temperate House, during December; Baikiaea insignis, which flowered at Kew for the first time in July, 1914, and has done so several times since, but never so freely as it did last year (in the Aroid House, No. 1); Agave americana and A. Ixtli, the latter being one of the Mexican fibre-producing species of value, and its loss consequent to flowering will be felt; and Thea (Camellia) speciosa, from Yunnan, China, which flowered quite freely at the latter end of the year. Several interesting South African plants in the collection obtained through the kindness of Captain Collingwood Ingram, flowered last year, including Monsonia speciosa and Kniphofia Galpinii, the latter being a species quite new to cultivation. The total rainfall at Kew for the year was 26·44 inches, 6·77 inches below that of 1927. The publication contains a list of the numerous contributions to the Gardens in 1928; one of the most valuable was the gift of over 3,000 bulbs of named Daffodils for planting in grass, by the Donard Nursery Company, and special acknowledgment is made to Major Lionel de Rothschild for his generosity to the establishment. The issue also contains an account of the year's happenings at the National Pinetum at Bedgebury, and of the work carried out in the Museums, the Jodrell Laboratory, and the Herbarium, and it concludes by recording the extensive additions, received as presentations, to the Library.

The Double Coconut.—An interesting account of the introduction of the Double Coconut, Lodoicea Callipyge (L. sechellarum) into the Botanic Gardens of British Guiana, is given by Mr. Abraham, the Assistant Superintendent of the Gardens, in the December, 1928, *Agricultural Journal* of British Guiana. After several fruitless attempts to germinate seeds imported from the Seychelles, success was achieved in 1892 when, from twelve nuts, two females and one male plant were raised. The female flowered after fourteen years and the male in 1908—two years later. The Palms were practically stemless when they produced their first inflorescences. Now, at the age of thirty-five years, the females have stems two feet high, and the male overtops them by fully half-a-foot. Needless to say, what these Palms lack in stem they make up in leafage; for, as the photograph accompanying Mr. Abraham's article shows, the Palms have numbers of huge, fan-shaped leaves.

New Horticultural Instructor for Buckinghamshire.—Mr. Alan E. B. Langman, Horticultural Lecturer at the Cheshire School of Agriculture, Reaseheath, Nantwich, has been appointed to succeed Mr. Philip Mann—recently retired—as Horticultural Lecturer and Adviser for Buckinghamshire.

British Science Guild.—At a public meeting, held at the Mansion House on Wednesday, April 24, under the auspices of the British Science Guild, dealing with developments of British chemical manufacturers, Sir Frederick Keeble, C.B.E., F.R.S., spoke on a subject of great interest to horticulturists, namely, "Fertilisers from the Air." After briefly sketching the methods adopted in nature to convert atmospheric nitrogen into a form capable of assimilation by plants, the speaker turned to the question of the fixation of nitrogen and artificial fertilisers obtained by this means. He stated that Belgium and Holland consumed larger amounts of these fertilisers per acre than any other countries. In England, the consumption showed little increase during recent years, the value of nitrogenous manures not, apparently, being appreciated to the extent that the wonderful results obtainable by their aid justified. We shall deal in greater detail with the subject of Sir Frederick Keeble's speech in the near future. Interesting addresses were also given by Messrs. A. B. Shearer, F.T.I., and Francis H. Carr, C.B.E., dealing respectively with "Rayon (Artificial Silk)" and "Synthetic Drugs."

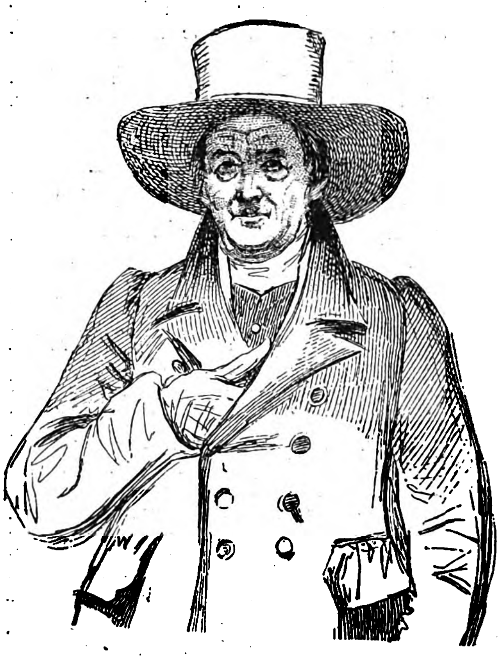
Birds at Kenwood.—A correspondent, writing in the *Daily Telegraph* of April 27, states that for many years several pairs of reed warblers nested regularly in the bushes in one of the ponds in Golders Green Park, but that during the war an over-zealous official cleared out the rushes from the pond, since when he had not seen the reed warblers there. Several species of birds which had temporarily left Kenwood have returned to nest there. The yellow wagtail and the coots nest there now, and two summers ago a pair of little grebes hatched out two young ones, but did not rear them. A few weeks ago a reed bunting was seen in Kenwood, a species which formerly nested there and may return.

French Vineries to be Restored.—One of the sons of the well-known vine-grower of northern France, M. Anatole Cordonnier, has taken in hand the reconstruction of the once-famous "Grapperies du Nord," under the title of "Grapperies de Bailleul." In a few weeks' time the first group of houses will be ready for occupation, and it is thought that the enterprise will recover all its former prosperity.

Plant Export by Ferry to Belgium.—By a recent decree, the Customs at Zeebrugge, Belgium, are now prepared to admit of the importation into that port, by train-ferry, of living plants other than Vines. The advantage of this mode of transport for perishable goods is obvious, as it avoids a considerable amount of handling which would otherwise be necessary. For instance, eggs, fruits, vegetables, plants, etc., which are sent by ferry from Belgium, are placed in sealed wagons at the point of departure and are only opened by the Customs authorities on arrival in London. The train runs on to the ferry at Zeebrugge, and from the ferry on to the Great Eastern lines at Harwich, whence it leaves immediately for Liverpool Street.

Linnean Society's Anniversary Dinner.—Sir Sidney F. Harmer, F.R.S., President, will preside at the Anniversary Dinner of the Linnean Society at the Criterion Restaurant, Piccadilly Circus, on Friday, May 24, 1929, at 7.15 p.m. Fellows and Associates may invite friends, and must obtain tickets for the Dinner, price 8s. 6d. each (exclusive of wine), from the Assistant Secretary, Burlington House, Piccadilly, W.1., not later than Tuesday, May 21.

International Agricultural Institute.—On April 10 and succeeding days, a Conference was held in Rome, at the International Agricultural Institute. No fewer than eighty-four delegates were present, representing over forty different countries, including England. The subject of international phytopathological problems was fully discussed, but it is apparently very difficult to obtain agreement on questions of quarantine and import regulations in the various countries, which at present make and enforce their own laws according to their own particular circumstances. A resolution was, however, agreed upon to the effect that in cases of difficulties arising between one country and another in the application of import regulations, or doubt as to the underlying reasons for the creation of barriers to free importation of plants, recourse should be had to the Institute for arbitration purposes. After the close of the Conference, the delegates were entertained to a reception by the President of the Institute, M. de Mechelis, and his wife.



GRANT THORBURN.

(see p. 328.)

The Studley College Flower Show.—The show and sale of produce in aid of the Studley College Appeal Fund, held on April 25, was good from a decorative point of view, although we wonder whether, financially, it was a success. The large majority of the nurserymen who had exhibits at the R.H.S. meeting on the two previous days, left their groups intact, and these constituted the bulk of the display, supplemented by numerous stalls of flowers and dairy produce for sale, together with exhibits demonstrating work done at Studley College. Princess Mary, Viscountess Lascelles, opened the show a few minutes after 12 o'clock, and at that time there was a fair attendance, but throughout the afternoon the number of visitors was disappointingly small, although this had no diminishing effect on the vigour with which the numerous saleswomen plied their wares.

Memorial to "Pathfinder."—The late Mr. Edmund S. Taylor, known as "Walker Miles" and "Pathfinder," was well-known to those many ramblers who love the by-ways of the countryside rather than the highways. He had a genius for finding out and describing tracks that led through beautiful country or led to charming views, and his directions and descriptions were embodied in a series of booklets. To perpetuate his memory, a memorial has been placed on the top of Leith Hill, Surrey, and it takes the form of four bronze view indicators on the tower. Through the generosity of Mr. J. Andrews, Leith Hill is now the possession of the nation, and he was present on a recent Saturday when three hundred "ramblers" met to see the memorial duly dedicated by Lord Farrer, and handed over to Mr. H. W. Vaughan Williams, who accepted it on behalf of the National Trust.

Members' Day at East Malling Research Station.—A large number of Associate Members were present on the occasion of the Annual Meeting and Gathering at the East Malling Research Station, Kent, on April 30, and a very pleasant day was spent inspecting the valuable experimental work that is being carried out. The only flaw to the full enjoyment of the visit was the absence of Mr. Ronald G. Hatton, the genius directing the work at East Malling, who was unwell, and many expressions of sympathy were conveyed to him through Dr. R. C. Knight, the Assistant Director, who proved an admirable substitute. The Annual Meeting was held in the morning, and was presided over by Mr. P. Manwaring, an ardent supporter of the Institute. Both the Annual Report, a splendid and very useful publication in itself, and the Balance Sheet, were adopted, with no other comments than of praise and satisfaction. At 12.45 p.m., the large gathering partook of an excellent luncheon, which was terminated by speeches by Major Walter Elliot, M.P., Under-Secretary of State for Scotland, and Chairman of the Research Department of the Empire Marketing Board, who spoke enthusiastically of the great value of the scientific work in progress at East Malling, not only to fruit farmers in Kent, but to agriculturists in general throughout the Empire, and promised the station the Board's continued support; Sir George Loyd Courthope, Commander Bellairs, M.P., for Maidstone, and the Rt. Hon. Lord Cornwallis of Linton, who has long been keenly interested in the development and work of the station. Previous to these speeches, Mr. Manwaring, who presided, briefly outlined the history of the Institute which, since the war, has grown and developed rapidly, and at the conclusion he issued an appeal for assistance in establishing an Endowment Fund. After luncheon, the members divided into three parties and were conducted round the plantations and laboratories by members of the staff. The pruning and rootstock experiments proved extremely interesting, as also did the spraying demonstration with two high-power machines—the demonstration was of spraying with lime-sulphur wash (one in thirty, with gelatine as a spreader, at the pre-blossom stage). The Plum, Pear, Black Currant and Gooseberry plantations were visited, and the inspection of the work now being carried out in the laboratory, especially in the Entomological and Mycological sections, proved very instructional, especially to commercial fruit-growers. All the members must have left in the evening, after such an enjoyable day, with the feeling that, at East Malling at least, work of real value to the fruit-growing industry is being carried out.

The Royal Botanical and Horticultural Society of Manchester and the Northern Counties.—After a lapse of nearly fourteen years, this Society has again come to the fore, its re-awakening being marked by a very successful Spring Flower Show, held in the Organ Chamber of the Manchester Town Hall, on April 18 and 19. The show is described as a "feeler," to discover whether or not Manchester has sufficient flower-lovers to justify resumption of activities on the part of this, we suspect, particularly wealthy Society; if the spring show is regarded as a success, another vigorous effort will be made to re-establish the city as a horticultural centre. The quality of the exhibits at the show was surprisingly good in view of the extraordinary weather that has prevailed, and the trade was admirably represented. Spring flowers were, of course, most in evidence, but there were also several good collections of Orchids, and also a fine display of Hippeastrums. Allen C. Roy, Esq. (gr. Mr. Falconer), Cheadle Royal, was first in the class for a group of spring-flowering plants; Messrs. Backhouse (York), Ltd., staged the best alpine exhibit; and J. B. Adamson, Esq., Blackpool, the best collection of Orchids.

Chinese Rhododendrons at Kew.—A few of the newer Rhododendrons introduced from China and Tibet are on the borderland of hardiness. A considerable number flower and commence to grow during mild intervals in early spring, consequently the value of a cool, or unheated greenhouse, such as the new annexe to the Temperate House at Kew, has been very fully shown during the past winter. In the outdoor garden there are many losses among Rhododendron plants, and especially among flower buds, but planted out in the borders of the new house there is quite a different tale to relate. A few of the most noteworthy are R. coriaceum (Forrest 16,364), white with crimson markings, belonging to the 'Falconeri' series, from south-eastern Tibet; R. Morii, blush-pink (Wilson, 10,955), from Formosa, 'Irroratum' series; R. neriiflorum, deep blood-crimson, the type of a series, first introduced by Forrest from the Tali range in 1906; R. aureum, a dainty, small-flowered, rich yellow species, first introduced by Forrest in 1906, 'Campylogynum' series; R. bullatum, a very free-flowered, small plant with large, white blossoms, from north-west Yunnan, 'Edgeworthii' series; R. stenoplastum, blush-pink, with crimson markings, from western Yunnan (Forrest 17,920), 'Heliolepis' series; R. stereophyllum, white, from Yunnan, 'Triflorum' series; R. Davidsonianum, white, tinted rose, introduced by Wilson in 1903 from west Szechuan, 'Triflorum' series; R. floccigerum, a very pretty, cerise-red shade, from north west Yunnan, 'Neriiflorum' series; R. mollicomum, resembling R. racemosum, but with very hairy stems and leaves and pale rose flowers, from Yunnan, introduced by Forrest in 1913; R. Schlippenbachii, a very beautiful pink-flowered Azalea from Korea; and R. Weyrickii, with attractive brick-red flowers, also from Korea. Perhaps the most interesting plant in the house at the time of writing is a new species—Forrest 21,706—a dwarf bush covered with rich rose-pink blossoms.

Retirement of Mr. H. Dunkin.—After twenty-eight years' service as Horticultural Adviser and Organiser to the Warwickshire County Council, Mr. H. Dunkin is retiring on May 31, next.

One Hundred Years Ago. — The following quaint advertisement is culled from the *Aberdeen Journal* of April 29, 1829. Modest and unpretentious the exhibition may have been, but it proves how thoroughly alive, even in those far-off days, our gardeners were to the benefits of co-operation, fraternity and comparing of notes :—"Aberdeenshire Horticultural Society.—The First Competition of the Society for the year will be held in the Hall of the New Inn on Tuesday, the 5th of May. The articles for competition are :—3 pots stage Auriculas; 3 pots seedling Auriculas; 3 pots of Polyanthuses; 3 pots of seedling Polyanthuses; 3 Hyacinths; 12 Mushrooms; 25 Heads of Asparagus; 3 heads of Broccoli; a brace of Cucumbers; 12 dessert Apples; 6 heads of Sea Cale; and for 3 quart bottles (each) home-made wine, from fruit or vegetables, either single or combined, the growth of the counties of Aberdeen, Kincardine or Banff, without the assistance of any foreign ingredients but sugar."

Inspection and Certification of Strawberry Plants.—The Ministry of Agriculture and Fisheries is prepared to accept applications for the inspection of stocks of the following varieties of Strawberry plants with a view to their certification if found to be true to type and reasonably free from rogues :—Bedford Champion, Jucunda (Amazone), Leader (Kentish Favourite), Madame Kooi (Princess Juliana), Madame Lefebvre, Oberschlesien, Royal Sovereign (Laxton's King George V.), Sir Joseph Paxton, Stirling Castle (Garibaldi), The Duke and The Laxton. The certificates which may be obtained are of two kinds: (*a*) "Ordinary" and (*b*) "Super" certificates, the latter being issued in cases where a prescribed limitation of runners is practised by the grower. The fees payable for inspections are at the rate of 10s. per acre or part of an acre on application for an "Ordinary" certificate, and 15s. per acre or part of an acre on application for a "Super" certificate. Full details can be obtained from the Ministry. Growers wishing to participate in the scheme should bear in mind that applications for inspection must reach the Ministry not later than May 31, 1929; applications cannot be accepted after that date.

Legacies to Gardeners. — Mr. Alfred Hobson, of Redcliffe, Dawlish, Devonshire, who died on February 9, left £1,000 to his Gardener, Mr. Sydney P. Brown, and £200 and £50, respectively, to Mr. Leonard Ash and Mr. Fred. Stevens, under-gardeners, if in his service at the time of his death.—Under the will of the late Mr. W. G. Welch, of Hampson, Galgate, near Lancaster, who died on January 2, Mr. W. Miles Whittingham, his gardener, receives £200, and £1 a week.

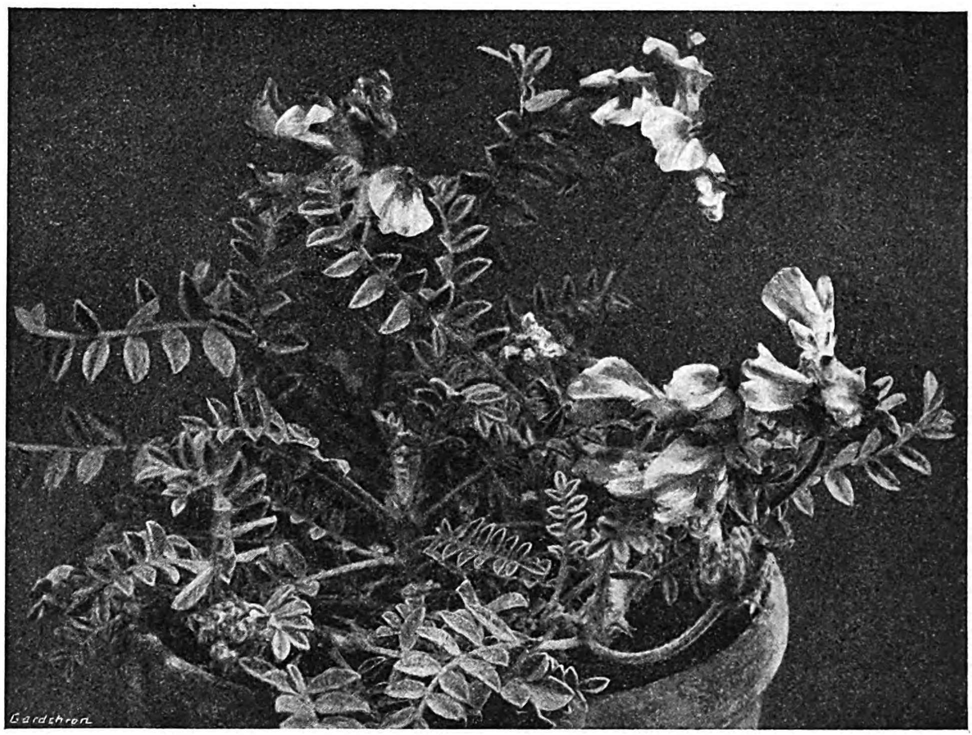


FIG. 160.—ASTRAGALUS UTAHENSIS.

R.H.S. Award of Merit, April 23. Flowers rose-purple; leaves silvery. Shown by C. T. Musgrave, Esq., Hascombe Place, Godalming. (see pp. 316 and 327.)

Moreton Paddox Gardens.—By the kindness of the owners, Captain and The Hon. Mrs. Carlano Emmet, the gardens at Moreton Paddox, near Warwick, will be open to the public this year on Sunday, May 5. The wild garden with its grottos, pools and shrubs, planted and arranged by Major Robert Emmet, D.S.O., father of the present owner, is particularly beautiful this year, and those who are able should not miss this opportunity of visiting the gardens, which will be open under the scheme organised, as in 1928, by the Queen's Institute of District Nursing.

Appointments for the Ensuing Week.—MONDAY, MAY 6: Harrogate and District Horticultural Association's meeting. TUESDAY, MAY 7: Royal Horticultural Society's Committees meet (two days); Royal Caledonian Horticultural Society's meeting. WEDNESDAY, MAY 8: Sheffield Chrysanthemum Society's lecture. FRIDAY, MAY 10: Royal Horticultural and Arboricultural Society of Ireland's meeting. SATURDAY, MAY 11: Leeds Paxton Society's Tulip Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*How to obtain Potatos free from Disease.*—I have been successful in producing sound crops by the following course of culture: I procure as early and good kinds of Potatos for sets as I can get, omitting all the very latest varieties. My next object is to plant so that the crop can be properly protected and saved from blight when the tubers are grown; I therefore grow my Potatos in beds, which I find to yield the heaviest and finest crops. The sets, which are cut, are sprouted on the hard floor of some sheltered shed, where they can have plenty of air and light. Here I cover them over with some dry mould or coal ashes, in order that they may grow and root, and they remain in this condition until the second or third week in May, when they are planted. After preparing the ground for them, mark out the beds six feet in width, and any length the land will afford, leaving the alleys between the beds three or four feet wide. The Potatos are put in at one foot square, keeping the rows straight. The land being planted, growth will soon become strong, and a little earth will be required, which must be supplied from the alleys. When properly earthed, which should be done twice, the plants may be left to grow undisturbed. Watch carefully for disease, and the moment it is perceived lose no time in cutting off the haulm and clearing it away. Then sprinkle lime, sulphur, soot, or salt over the beds, and cover them over with earth from the alleys, five inches deep, allowing the middle of the bed to be highest, in order to throw off rain, and keep the Potatos as dry as possible. The whole may now be left with safety. In this way the tubers will keep as sound as possible, and a bad one will scarcely be found. *J. G. Knell, Gard. Chron., May* 6, 1854.

Publication Received.—*The Book of the Tulip*, by Sir A. Daniel Hall, K.C.B., F.R.S.; pp. 224, with twenty-four full-page plates, twelve in colour; Messrs. Martin Hopkinson, Ltd., 23, Soho Square, W.1. Price 21s. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Calanthes.—The deciduous Calanthes, which have been resting since they finished flowering, are now starting into growth and, to avoid injuring the new roots later, the pseudo-bulbs should be repotted when the young growths are at a very early stage of development. Remove all old compost and only retain about one inch of the old roots at the base of the pseudo-bulbs to hold them in position. Only the last-made pseudo-bulbs are required for each lead. Examine these carefully, before repotting, for scale insects, which are easily removed at this stage with a weak insecticide, applied with a soft brush. Strong-growing varieties may be potted separately in pots of suitable size, which should be clean and well-drained. Smaller-growing or less vigorous kinds may be grown in groups in larger receptacles. A suitable rooting mixture consists of three parts good fibrous loam, one part dried Oak or Beech leaves, well broken up, one part of finely cut A.1. fibre, and a little chopped Sphagnum-moss, adding charcoal or crushed crocks to ensure porosity. First cover the drainage with some of the rougher pieces of the compost to prevent the finer soil from choking it, and then make the compost firm about the bases of the pseudo-bulbs; the young growths should not be covered or decay will set in; leave ample room for copious waterings later in the season. Grow the plants near the glass in a warm house, and shade lightly from strong sunshine, allowing more sun and air to reach the plants as the pseudo-bulbs mature. No water will be needed at the roots until the plants are well established, but the surroundings and pots will require frequent syringings to encourage root action. As the growths advance and new pseudo-bulbs begin to form, copious watering will be needed each time the soil appears dry, while an occasional application of weak liquid manure will prove beneficial at this stage, but any feeding should be discontinued as the flower buds begin to show on the scape. Any desired increase of stock can be made by placing the old, sound pseudo-bulbs which were removed, in a little moss, in a warm house, where they should be sprayed occasionally until they start into growth, when they may be potted up into small receptacles and grown on with the larger plants.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—As the time for bedding down the plants is drawing near, it is of the utmost importance that all perennial and other weeds should be eradicated and the plantations made so clean as possible. Recent rains have improved the appearance of the plants considerably, and there is still time to apply some artificial manures for their benefit, for they have passed through a very trying period. The following mixture should suit most soils:—Four parts of bone-flour, two parts of sulphate of potash, and one part of sulphate of ammonia. Apply one good handful per yard of row, and sprinkle it close up to the plants on both sides, taking care to avoid the young foliage. This manure should be worked lightly into the soil, and, in doing so, draw the soil up under the basal leaves so that it may benefit the surface roots. If old soot is obtainable, the ground between the rows should receive a good dusting. Besides being a valuable manure on all soils, soot is also a deterrent to slugs and millipedes, which are often very destructive to the ripening Strawberry fruits. Once the plantations have been thoroughly cleansed it will be found advantageous to bed down the plants immediately, as a protection from frost, and also from the point of view of economy in labour. Long, strawy litter from the stable should be laid down between the rows, tucking it well up to the plants for their immediate protection and to keep the fruits clean. Failing this litter, recourse must be made to straw, which is much more expensive, and possibly not so good for the purpose. The point, however, is to get it on before the plants come into bloom, and to apply plenty.

Stock Strawberry Plants.—Maiden plants from which it is intended to propagate, either for forcing or for furnishing new plantations, should not be allowed to fruit. The flower trusses should be removed directly it is seen that the flowers are normal. This early removal of the flower trusses will divert the whole energy of the plant into the early production of strong runners and healthy plantlets. This is very important when the plants are required for forcing, and also when the Strawberry plants are treated as annuals for the production of first-class and early dessert fruits.

General.—During dry spells, keep the hoe going in the fruit quarters to check seedling weeds. By the diligent use of the hoe not only are weeds destroyed, but moisture is conserved and air is admitted into the soil, these being very important factors in fruit cultivation.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Edgings.—Edgings in the flower garden are of various forms, and may be divided into two classes, the permanent, *i.e.*, those composed of dressed stone or tiles, and those of living plants. Of the former, little may be stated to their advantage, beyond that they are permanent and require the minimum of labour in upkeep. But the latter have much in their favour, as there is a wide range of plants at our disposal for such purposes, and the labour of upkeep is not too expensive. Of the numerous plants suitable, the Box is one of the most popular, having been used universally for ages; it is valuable for making a close, attractive edging to the formal garden. Where this is used, it should be clipped with care to the desired shape during late April or May, when the likelihood of frosts is past. By deferring the cutting so late as possible, the young growths soon cover the shear marks. Another plant that may be used with even greater effect for this kind of edging is Erica vagans, which has the added advantage of being extremely free-flowering during autumn. This makes an ideal edging in lime-free soils, and is easily kept in shape by annual clipping after flowering, or in early spring before growth commences. Where informal edgings are desired, natural stone is the best of all material to use. In many districts the material for this purpose is easy to obtain, and the stone of the district ought to be used always in preference to imported material. It should not be dressed and ought to vary in size and shape, as the stones should not be set rigidly in straight lines. By sinking them half their depth in good soil, homes for a host of interesting plants, which will give added charm to the flower garden during spring and summer, will be provided. Plants suitable for furnishing such edgings are Sedums, Saxifragas, alpine Phloxes, Candytuft, dwarf Veronicas, Thrift, Gentiana acaulis, G. verna, Helianthemums, Primroses, and a host of other alpine plants, while colonies of the early-flowering bulbs—Crocuses, Scillas, Chionodoxas, and the smaller forms of Narcissus, may also be planted, and will be a source of interest and pleasure for many months.

Cistuses.—These are among the most beautiful of flowering shrubs, but, being natives of south-western Europe and Asia Minor, they suffered severely during the past winter. When the full extent of the damage is realised, they may be pruned back to living tissue, but if the damage is very severe it will pay to replace them with young plants, as old plants seldom recover and grow freely after hard pruning. These shrubs prefer a dry, sandy soil, and in such a position will suffer less during winter than if planted in rich soil. There are many beautiful kinds, all of which are worth trying in the south, if suitable soil and situations are available. Cistus laurifolius is one of the hardiest kinds, having white flowers with a small yellow blotch at the base of the petals. C. ladaniferus, the Gum Cistus, is one of the best, and will be found to grow and seed freely on dry banks. C. purpureus is fairly hardy and extremely attractive when in bloom. C. florentinus forms compact bushes two-and-a-half to three feet high, covered with myriads of white flowers. C. cyprius is not unlike the Gum Cistus in character, but bears its flowers in clusters, instead of singly, while C. villosus and its various forms are also worth trying. Among recent introductions, that fine variety Silver Pink should not be overlooked. This seems quite hardy, it has flowers of charming colour, and it does not drop its petals so quickly as other sorts, while it is very free-flowering. C. formosus is rather tender, but is such a beautiful plant, with its bright yellow flowers, each petal having a purple-brown blotch at the base, that a position such as the top of a dry, sunny wall should be allotted to it, and cuttings taken each autumn, inserting them in a cold frame.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

The Early Orchard House.—Peaches and Nectarines will now be stoning, and careful attention to feeding, maintaining a steady temperature, early closing to trap the sun-heat, and good syringings, is essential. Once the fruits begin to swell, lateral and sub-lateral growths may be shortened back by degrees to let in light and air, and also to increase the size of the fruits. Progress will now be rapid, and liberal supplies of warm, diluted liquid manure will be necessary. The supply of air at night may now be gradually increased, but not so as to lower the temperature too much, and should be shut off early to favour a rise in the temperature for morning syringing. Ventilation may be given when the temperature is at 65° to 70°, rising to 80°, which, with full air, should be the maximum. Reduce the air supply early, finally closing the ventilators in time to allow the temperature to rise to the maximum by sun-heat. Trees in unheated houses must have plenty of air throughout the day, and watering and damping should be done early in the day, especially if morning frosts are likely to occur, and if the houses face full south.

Planting Vines.—If Vine eyes were inserted and the young plants are required for permanent planting, the middle of May, or whenever the borders are ready and the young canes are about two feet in height, is a good time to plant them. Even when planted so late as the second week in June, other conditions being favourable, the canes will top the rafters before autumn, although, if they are well rooted and the soil is thoroughly warm, the end of May is the better time. The secret of success lies in getting the compost, consisting of fresh turf, bone-meal, and old lime-rubble, made up and thoroughly warmed by the time there are sufficient roots to hold the balls of soil together when the vines are turned out of the pots. A border four feet in width and two feet six inches deep, above ample drainage, is quite large enough for the first year. Sun and fire-heat will soon raise the temperature of the border, so that the Vines may be transferred without being checked. Having well watered the soil in the pots overnight, turn the vines out carefully, gently disentangle the growing points of the roots without breaking the ball to pieces, and plant them shallowly, packing the warmest compost firmly about the roots with the hands, after which cover the surface of the ball with one inch of soil. Train the cane to a stick and keep the house close and moist, and lightly shade from bright sun; defer watering for a few days, unless the compost is very dry. After the vines have started into fresh growth, give a good watering through a rose (the water should be at a temperature of 80° to 85°) to settle the soil, and as growth proceeds, syringe and water the vines well;

by this time the shading may be omitted, except for an hour at midday if any of the vines show signs of flagging. A little fresh horse manure spread lightly around each, will complete their requirements.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Primulas.—Seeds of Primula obconica may now be sown to obtain plants for winter flowering. An improved strain may be secured in many shades of colour that are well worth growing for the embellishment of the conservatory. Seeds of this Primula are sometimes slow in germinating, therefore care is necessary not to sour the soil by frequent applications of water; the seeds should be covered very lightly and the soil should be moist when sowing takes place. Cover the receptacles with a piece of glass and plunge them in a box containing damp moss, and shade from bright sunshine. An early batch of Primula sinensis may be sown to produce autumn-flowering plants.

Flowering Shrubs.—Shrubs that have been forced will require careful treatment after flowering if they are to remain in good condition. Dwarf plants of Prunus, Staphylea, Forsythia, Deutzia and Spiraea, should have their growths thinned, and where possible, should be afforded cool treatment under glass for a short period. A cool orchard house affords ideal conditions. Standard specimens of Wistaria, Prunus, Laburnum, etc., should only be cut back to ensure the formation of shapely heads. The plants will benefit by frequent applications of weak liquid manure, and when conditions are favourable they may be syringed twice daily to assist them to break into fresh growth. Grown under these conditions until the danger of frost is over, they will repay the extra trouble bestowed on them, after which they should be plunged in ashes or some other material out-of-doors, where they may receive constant attention with regard to watering and feeding.

Coleus thyrsoideus.—Stock plants of this Coleus are now breaking into growth and, so soon as the young shoots are about two inches in length, they should be taken as cuttings and inserted three or more in a small pot filled with an open compost. When rooted, they may be potted singly, or repotted and grown on intact. This Coleus is very easily grown and produces its flowers in the dullest months of the year; it is useful for supplying cut flowers, or for grouping purposes.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Plants in Frames.—Seedlings in frames should be watched carefully to ensure they do not suffer through lack of water. They should be examined every morning for this purpose. Further advanced crops in frames may be given an application of liquid manure.

Rhubarb.—The Rhubarb seedlings should now be ready for pricking out into boxes or four-inch pots in a compost of good loam, sand, and a little leaf-mould. Grow them on in a cool frame until they attain a fair size, when they may be hardened off properly and planted out in ground that has been well-tilled and enriched with a dressing of decayed manure. Rhubarb crowns that have been forced should be replanted; these forced crowns, if treated liberally, make good stools for forcing again in two or three years time.

Potatos.—When the growths of the early Potatos are a few inches above the ground, soil should be drawn up to them on either side so early as possible, so as to provide some protection from frost; but if severe frosts are likely to occur, as often happens at this season, branches of Spruce or other light covering may be laid over them to protect them, removing it each morning so early as practicable.

Tomatos.—The young Tomato plants, which are intended for planting in the open garden later, will now require repotting into larger receptacles, after which they should be grown on in a cool frame, hardening them off gradually, and completely, so that they will be ready for planting out so soon as all likelihood of frosts has passed.

Marrows.—The beds for these should now be prepared, and may be made up of any rough vegetable matter, leaves, decaying manure and good loam, which should be well mixed together. Seeds may now be sown in pots or boxes, and germinated in heat. Transfer the seedlings to a cool frame so soon as the cotyledons have developed, and gradually harden them off. There is nothing to be gained by sowing the seeds too early, unless plenty of frames are available and the seedlings may be grown on in a steady temperature, and kept free from night frosts.

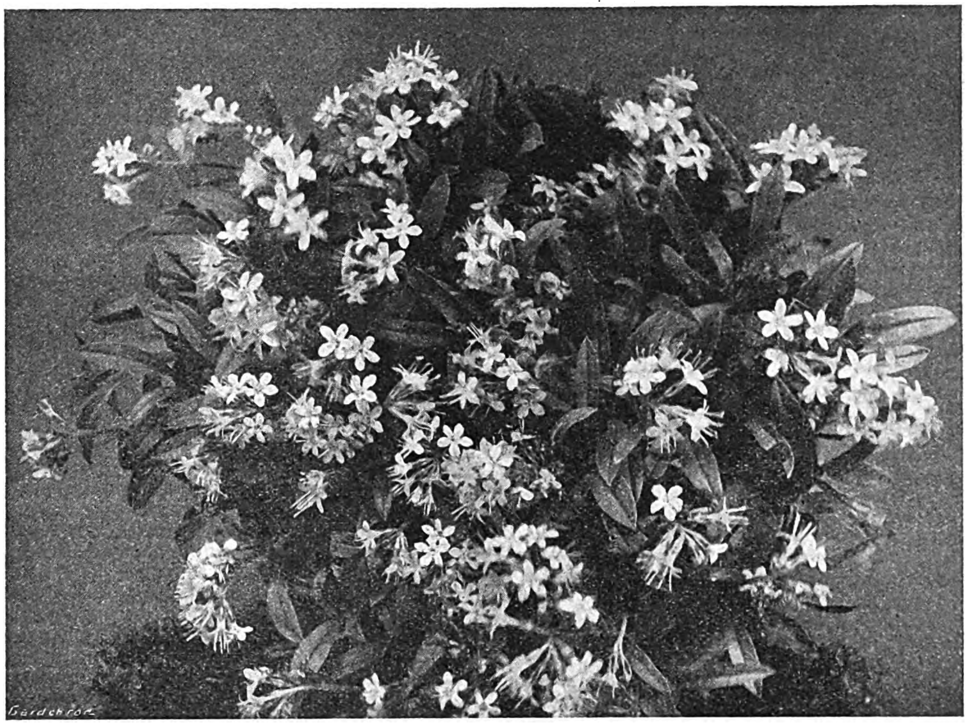

FIG. 161. MERTENSIA MOLTKIOIDES.

R.H.S. Award of Merit, April 23. Flowers blue. Shown by Mr. T. Hay, Hyde Park. (see pp. 316 and 327.)

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Carrots, Beets and Salsify.—The main crops of these should be sown at an early date. Where the soil is stony or very heavy it pays to adopt the holing system if at all possible, for Carrots especially. The soil used to fill the holes should be sandy, without any rich material added, the whole being passed through a half-inch sieve. Not more than four or five seeds should be sown in each hole, and the latter should be ten inches or twelve inches apart.

Onions.—Plants that were raised in heat and have been well hardened off, should now be transferred to their growing quarters. If one can anticipate rain and have the planting done while the ground is moderately dry, so much the better, but no time should be lost now. If the ground has been prepared as suggested previously, it should now be given a good dusting of soot, wood ashes and an approved fertiliser, these being hoed in and the ground trodden well. In the case of transplanted plants, twelve inches apart each way, or even a little more, should be allowed, but seedlings direct from the seed-box need only be planted five inches or six inches apart in the rows. A trowel should be used for planting and as many roots retained as possible, the soil being well pressed around the plant to keep it upright; avoid deep planting. If the soil is wet at planting time, loosen the surface soil between the rows with the Dutch hoe so soon as it is sufficiently dry, to prevent it caking.

Sweet Peas.—Spring-sown plants should be planted so soon as possible. If from pots, release the roots a good deal from the ball before planting, and in every case spread them out well, making a hole large enough to allow of this. In the case of "mossed" plants, no trouble in this respect will be experienced. If Basic slag was applied earlier when preparing the trench, nothing further need be added to the soil at present.

Helleborus niger.—The tall form of this is well worth cultivation. Permanent beds should be pointed over, working in plenty of good, old manure, and if liquid cow manure is available, frequent applications of it on wet days at full strength, or in dry weather much diluted, should build up good crowns. Although impatient of disturbance, the clumps may be broken up and transplanted successfully if care is exercised. A partially shaded position and rich but not too retentive soil, suits Hellebores well.

Violets.—The Violets in frames having finished flowering, they should now be broken up and planted in their summer quarters. A cool, rather shady position should be selected for them and, if the soil has previously been deeply cultivated, a good quantity of old leaf-mould, and on heavy soil, sand, should be spread over the surface and worked in among the roots when planting. A spade is the best planting instrument to use, as the roots can then be spread out properly—one of the first essentials to success. The double varieties, such as Marie Louise, Mrs. J. J. Astor, etc., should be planted a foot apart each way, but with the larger single varieties, like Lloyd George, six inches more should be allowed. See that the collar of each plant is well down in the soil, to prevent loosening and to encourage rooting from just beneath the crown. Water if necessary and spray the plants in the evenings of dry days until root action commences. If cuttings were inserted in frames in autumn, they naturally make better plants than suckers or divided plants, and should be planted in preference.

INDOOR PLANTS.

APHELANDRA TETRAGONA.

I read with interest Mr. Barker's article on Aphelandra aurantiaca var. Roezlii in your issue of February 23 (p. 137). While this is an attractive plant when well-grown, I do not agree with Mr. Barker that it is the most handsome of all Aphelandras. I would venture to suggest A. tetragona occupies this position. Its flowers are similar in colour to those of A. aurantiaca var. Roezlii, but are larger and borne on spikes six to eight inches long. Plants raised from cuttings rooted in the autumn or early spring attain a height of two-and-a-half feet the first season, and when well grown will come into flower during early November. This plant, however, is seen at its best when two years old, and after flowering the growths should be shortened back and the plant given a slight rest before being started into growth again early in the New Year. In other respects its cultural requirements are similar to those given by Mr. Barker for A. aurantiaca var. Roezlii.

A. nitens is also well worthy of a place in the stove, with its scarlet-vermilion flowers springing from shoots bearing polished, green leaves. *J. N. McGoogan, Wisley.*

CELOSIA PLUMOSA.

Few plants make a more charming and brilliant display during the summer and autumn months than Celosias, and when well-grown they are invaluable for furnishing the conservatory or flowering-plant house, or for drawing room decoration; they are also ideal plants for the exhibitor when staging a group of miscellaneous foliage and flowering plants. Yet, in spite of its general utility, a well-grown batch of C. plumosa is seldom seen, although this plant is in no way fastidious.

Undoubtedly, the purchase of a good strain of seeds has a lot to do with the success which the grower hopes for; it is inviting failure to attempt to grow a good batch of plants from a packet of cheap and inferior seeds. Obtain the seeds from a reputable seedsman and sow them in pans of light, rich soil consisting of finely sifted loam, leaf-mould, peat and sand in equal parts; give plenty of drainage, cover the seeds but slightly, and plunge the pans on a hot-bed or stand them in a warm house; a Cucumber or Melon house will do admirably. Place a sheet of glass over the pans and keep the soil moist; germination should take place in a few days, when the glass should be removed and the pans placed near the roof-glass in full sunshine. So soon as the seedlings are large enough to handle they may be pricked off in boxes or into thumb pots, the latter for preference, so as to avoid disturbing the roots during subsequent potting. Water them in, and then place them back on a shelf near the roof-glass in a warm house, a shelf in the stove makes an ideal place, or failing this, they may be placed near the glass in a newly-planted Melon house. It is essential at all stages of growth—except when the feathery plumes are fully developed—to keep them exposed to the sun, and they should not at any stage be allowed to become root-bound. So soon as the roots are observed around the edge of the pot when turned out the plants should be potted on into three- or four-inch pots, using a compost of equal parts fibrous loam, leaf-soil, peat and dried cow manure passed through a quarter-of-an-inch sieve, with a liberal addition of silver sand. On no account should the soil be rammed hard at any potting, as this tends to make the plants flower prematurely. Keep them growing in a temperature of about 65° to 70°, and stake the growths so soon as is necessary; during hot, dry weather overhead syringing may be practised with beneficial results.

The final potting should be into six- or seven-inch pots, using a compost similar to that for the previous potting, but adding a sprinkling of Clay's fertiliser. Careful watering is essential after each potting, but the plants root quickly, and although excessive watering should be avoided, they should never be allowed to become dry at the roots. So soon as the flowering pots are full of roots, weak solutions of liquid manure, alternating with Clay's fertiliser, may be given with advantage once or twice a week. When the inflorescences begin to develop the plants may be gradually inured to cooler quarters and, if finally placed in a cool, flowering house or conservatory, they will remain in flower over several weeks. A succession of plants may be maintained by sowing seeds at intervals, the earliest sowing being made in the first half of April; if sown before this, lack of sunshine tends to make them flower prematurely, in which case they are useless.

Celosias are seldom attacked by pests, although red spider and mealy bug occasionally put in an appearance. The former may be kept in check by syringing and avoidance of too dry atmospheric conditions; the latter by applications of methylated spirit to the affected parts with a camel-hair brush.

If these cultural conditions are adopted, brilliantly coloured, feathery plumes—six inches or more long—in various shades of red, orange, yellow and magenta, may be confidently expected. *A. J. Turner.*

HARDY FLOWER BORDER.

HERBACEOUS VERONICAS.

Few genera of plants present such a wide diversity of habit, structure and appearance, as the Veronicas, for this family of plants contains numerous members of low, prostrate habit, many of which are eminently suited for culture on the rock garden; others are strong-growing herbaceous plants invaluable for furnishing borders in the flower garden; and yet a third group consists of shrubby species and varieties, mostly natives of New Zealand, and in the main, not hardy.

Of the herbaceous kinds, and it is the purpose of these notes to deal with these, some are old-established garden favourites—V. longifolia and V. virginica, for instance—and are to be met with in even the humblest of cottage gardens, but there are others with claims equal to these two species as first-class border plants.

Little need be written of V. longifolia and V. virginica, for they are both so well-known, in their several forms, as not to require description or to need extolling, although there is a variety of V. longifolia, namely subsessilis, which is not so well-known, nor so freely grown, as it should be, and is therefore deserving of mention. It is distinctly superior to the type, of erect, compact and bushy habit, and, if anything, of more vigorous growth, with large spikes, borne several on each stem, of closely packed, rich amethyst-blue flowers; it is a distinct acquisition to the border, as also is the slender spiked, bright rose-coloured form of V. longifolia var. Eureka. The varieties subsessilis, alba and Eureka constitute an admirable trio, for they brighten the herbaceous border from late June until early August.

V. spicata, in its several colour forms, is suitable for the front of the herbaceous border, so well as the rock garden, for its erect-flowering growths rise to a height of only one foot or so from a creeping, almost woody rootstock; they are clothed with downy, rather thick-textured leaves, and bear gradually elongating spikes of closely-packed, rich blue, white or pink flowers. This species, a native of Europe, including the British Isles, where, however, it is rare, is desirable in all its colour forms, for it is free-flowering—so long as it is grown in a sunny position and in not too rich soil—free-growing, and one of the easiest plants to increase by division; each growth, if pulled from the parent plant, will be found to have roots attached and will quickly become established. A variegated foliaged form of this species sometimes appears in lists, and is no doubt welcomed by those who delight in such things.

Another Veronica of exceptional merit is the dainty V. gentianoides—the resemblance of this species to the Gentian, as has often been remarked, is very remote—one of the earliest Speedwells to bloom. It has rather large flowers of the palest blue, flushed deeper on the margins, and produced during May and June; they are borne loosely in graceful racemes, twelve inches or thereabouts in height, above large, basal tufts of glossy, rich green leafage. Like the other species, V. gentianoides is free-flowering, but is not of such ample form, possessing a daintiness and airiness not often met with in this group of Veronicas, and comparable to the dainty-flowered V. Hulkeana in the shrubby section. This species also has a form with variegated foliage, often to be met with, but of rather anaemic appearance.

Although more often associated with the rock gardens than the herbaceous borders, yet V. incana is well suited to the latter and is, indeed, extremely attractive and effective when given a sunny position at the front, for few plants possess such a charming combination of colouring. V. incana forms a close, spreading mass of downy, silvery foliage, fresh and attractive throughout the summer, and then, in late summer silvery stems rise to a height of from nine to twelve inches, to be terminated by close spikes of rich violet-blue flowers which tone admirably with the silvered stems and foliage. V. incana is obviously a sun-lover, and to secure the best effect from it a sunny position should be afforded, and soil of not too rich composition.

And lastly, there is V. spuria, to give it its correct name, although it is more popularly known as V. amethystina, an appelative that admirably describes the colouring of its flowers, which are produced in gay abandon throughout June, so profusely, in fact, that each plant becomes a mound, one foot high and considerably more across, of bright amethyst-blue. V. spuria is a good perennial, free-growing, and impartial as to soil, so long as it is not so damp and rich as to cause luxuriant growth, which is not conducive to free-flowering. This also deserves a front position in the border, while, if it is planted in a sunny position in the wild garden, it will be found to naturalise itself, seeding itself about, and soon forming a very attractive colony, for it seeds as profusely as it flowers.

These herbaceous Veronicas are, as a group, the least exacting of border plants. The tall-growing sorts flourish in ordinary garden soil and do not object to partial shade; all they ask is to be lifted and divided every third or fourth year, replanting the outer portions of the clumps in freshly prepared soil. The dwarf kinds require sunny positions and soil of only moderate richness if they are to give of their best; they all produce seeds freely, and are easily increased by division. *M. W.*

TREES AND SHRUBS.

BERBERIDOPSIS CORALLINA.

The moist forests of Chile have enriched our gardens with many beautiful plants, and none, perhaps, so unique as Berberidopsis corallina, the only species of the genus. When well-established the plant grows freely, its long stems covered with hard, leathery, heart-shaped, evergreen leaves, with prickly edges and points. The inflorescence, often nine to twelve inches in length, varies in size according to the strength of the growth on which it is borne. The individual flowers, of wax-like texture, are somewhat similar to those of the Berberis, and hanging by thread-like stems have a very elegant appearance; but it is their colour, a rich, deep red, that renders them so conspicuous. It would appear that this colour and texture occurs but rarely, except under similar forest conditions, for instance, in Lapageria rosea, Tricuspidaria lanceolata, and some of the Himalayan Rhododendrons.

Being somewhat tender, the Berberidopsis needs the protection of a wall, and shade from the fiercest sun. It succeeds well on either east, west or north walls, especially if sheltered by adjacent trees. The addition of leaf-mould and sand to light turfy loam makes an ideal rooting medium. What is horticulturally known as peat, when used in quantity, is apt to turn sour and sodden after about ten years, a condition that may account for the death of many a fine plant. We lost one with a spread of twenty-eight feet in this way. Good drainage is essential. Like the Lapageria, its flowers are displayed to greatest advantage when hanging from a roof rather than on a wall, and the plant succeeds admirably as a climber on the shady side of a large conservatory. In such a position it loves moisture, and a good syringing towards evening as the sun loses power is very beneficial.

In pruning, early in spring, it is only necessary to cut out the exhausted wood and shorten any immature growths made late the previous autumn. Cuttings root readily, when about half-matured. Seeds are said to be produced but although several plants on open walls have been under my observation for over twenty-five years, I have never see any; warmer conditions or possibly pollen from another plant may be necessary. *J. Comber, Nymans Gardens, Handcross.*

SALIX BOCKII.

THIS in an ornamental Willow of considerable merit; it has proved to be a most accommodating plant, adapting itself to almost any conditions. Planted by the waterside it has much to commend it, while it does equally well in the rock garden, or in the foreground of shrubberies.

S. Bockii was introduced into this country in 1910 by Mr. Bean, who obtained it from the Arnold Arboretum, where it had been introduced from China in 1908 by Mr. Wilson. The specimen here has attained a height of four feet and is as much through, which is about its recorded stature. Its slender branches are thickly furnished with twiggy growths, which, when October arrives, are literally smothered with narrow, inch-long catkins; these are borne in the axils of the small, silky-hair-covered, oblong, mucronate leaves. The female is the form usually met with in gardens.

This species is, I believe, the latest-flowering member of the family Salicaceae. It is worthy of note that, should the weather be mild, small clusters of tiny, silvery leaves persist at the extremities of the twigs throughout the winter months. *J. Blades, University Botanic Garden, Cambridge.*

ERICA MEDITERRANEA.

GOOD as it undoubtedly is, the typical Erica mediterranea which one usually sees in gardens is excelled by a form generally listed as var. superba. Here, this excellent Heath is a trifle later in coming into flower than the type, but it is superior to the latter in the size and density of its flowering sprays. The individual flowers are also rather larger and of a brighter colour and they are borne in such profusion that a well-grown plant appears to be enveloped in a solid mass of bloom in May. The foliage of this form is a trifle darker, and the growth sturdier than in the typical shrub. Where there is only room for a limited number of plants, E. m. var. superba should always be chosen to represent this fine species.

E. m. var. alba is such an admirable Heath that one wonders why it is not more often grown. Being only about half the size of the type it is very suitable for small areas, and it can be used with good effect as a background in the bolder parts of the rock garden. With me, E. m. var. alba always comes into flower before others of its species, so that one can generally rely upon having it in bloom for Easter, even when this occurs in March. The flowers are a really good white, they are produced in densely packed spikes, and have a telling setting in the rich, glossy green of the foliage. In my light loam, E. m. var. alba does not much exceed two feet, and it is quite hardy.

E. m. var. hibernica (glauca) is a somewhat dwarf form of Irish origin, not often exceeding three feet. It does not flower with the abundance of the type, but the smoky effect of its glaucous foliage is a distinctive feature which is attractive in winter and a colour that goes well with the pale rose-purple blossoms. E. m. hibernica var. Brightness is not, as might be supposed, an off-shoot of the last-mentioned, but a green-foliaged Irish form of the type, with flowers of a clear rosy-crimson. It blooms freely, is compact in habit, and distinct enough to hold its own with honours. It grows some three feet high. There is a pink-flowered seedling from E. m. h. var. Brightness, known as rosea.

E. m. var. nana is a dwarf representative of the type species with little to recommend it beyond the fact that it does not often grow to more than eighteen inches. This would be a valuable little Heath if it flowered anything like as freely as does E. mediterranea proper, but in my experience it falls far behind the latter in that respect. But, taken as a whole, the Mediterranean Heaths (which, by the way, are of Biscayan origin) comprise a group which must always be regarded as among the most useful and beautiful of the genus. They are so hardy that none of my plants were injured during the recent frost, although the latter was severe enough to destroy the foliage and young plants of Calluna vulgaris. Moreover, these Mediterranean Heaths are in flower from March to May which means that they cover the entire period between the last of the winter-flowering and the first of the summer Heaths. The flowers, which are borne so freely, are deliciously fragrant and few Ericas are more easily grown. Almost any free soil seems to suit them, and even to lime they are not resentful. *N. Wales.*

OLEARIAS.

YOUR correspondent, *W. A.* (p. 227), does well in once more drawing attention to these valuable evergreen flowering shrubs, as they are particularly attractive and useful in many ways. O. Haastii is proving very suitable for town gardens, and it is to be hoped, will, in time, oust the commoner Laurels, etc., from suburban gardens.

In milder coastal districts, however, this variety grows much taller than the "four or five feet" mentioned, and it is not uncommon to find it twice that height, when it forms a most effective hedge or screen, which only requires to be lightly trimmed each season when the flowers are spent, in order to remove the withered blossoms, which tend to remain long after their beauty has passed.

O. Traversii has also been proved useful for exposed positions on the coast, and it was recorded in *The Gardeners' Chronicle* a few years ago that it was doing extremely well on the cliffs in the neighbourhood of Scarborough. It is a strong, quick-growing variety with glossy-green, rounded leaves, felted underneath, but with no claims as a flowering shrub, its small panicles of inconspicuous flowers being of little merit; but as an evergreen shrub for seaside gardens it is well worth growing.

O. Forsteri is another kind not so often met with as one would wish, as it makes a shapely bush up to twenty feet high, with pale, yellowish-green foliage, beautifully undulated, reminding one very much in appearance and habit of Pittosporum Buchananii. The foliage, on examination is, however, quite distinct, being heavily felted on the undersides and hard to the touch, while the Pittosporum is lacking in both these characteristics. The flowers of O. Forsteri are also of the inconspicuous type, and are produced late in the year, about October or November, in small, branched panicles.

So far as my experience goes, it is unusual to find self-sown seedlings in any quantity around established plants, although an occasional stray seedling of O. macrodonta may appear, but most Olearias are readily propagated by means of cuttings of half-ripened growths, inserted in frames or, in the milder districts, in the open border, during the late autumn. Another great point in favour of Olearias is that they withstand transplanting extremely well, and even fairly large specimens, which may have outgrown their original sites, may be moved if the usual precautions are taken to secure a good ball of roots, with every prospect of success.

The gem of the whole family is that mentioned by *W. A.*, O. semi-dentata, to which I was introduced by the generosity of Sir Herbert Maxwell, Bart., a number of years ago. It is a most attractive form, and when its lanceolate, silvery-green foliage is bedecked with the comparatively large, mauve flowers in June, it is undoubtedly one of the treasures of the garden, whether, owing to the exigencies of the climate, it is allowed the benefit of a wall, or left in its more natural state as a symmetrical bush in the open.

To all these mentioned may be added many others, which are not yet well known, such as O. argophylla (Musk-scented), O. chatamica, O. ramulosa and O. Solandri; and if I might make a humble suggestion re that invaluable work by Mr. W. J. Bean, *Trees and Shrubs Hardy in the British Isles*, it is that in any new edition a fuller list of Olearias known to thrive in this country should supplement the present somewhat limited number given. *A. T. Harrison.*

ROSMARINUS OFFICINALIS VAR. PROSTRATUS.

THIS small counterpart of the common Rosemary is a delightful, prostrate shrub, rich in all the happy associations of its more ample congener, and very beautiful when established and draping a boulder or rocky slope in full sunshine; unfortunately, this plant has withstood the severe winter indifferently, so that only specimens growing in mild districts or congenially placed, have passed through the ordeal successfully. A sharply-drained soil and a high position in close proximity to rock, are conditions conducive to longevity, and a small stock of plants—they are easily raised from cuttings—should invariably be wintered in the cold frame or greenhouse.

The grey-blue flowers so profusely starring the closely-set branches, invest this little shrub with arresting beauty, and a well placed group will be a cool, refreshing feature of the rock garden. *Ralph E. Arnold.*

DAPHNE MEZEREUM.

As the harbinger of spring, Daphne Mezereum must surely be given pride of place among shrubs, blossoming as it does during the first three months of the year. The flowers, which are deliciously fragrant, and rose-purple in colour, are produced in profusion from the lateral buds on the wood of the previous year—the terminal buds produce leaves and wood growths only. The flowers are succeeded by bright, coral-red berries which are one-seeded, and, if sown when ripe, will produce plants true to type. This affords a ready means of increase. D. Mezereum is of very slow growth in a young state, taking four years or more to attain any size, but it may, however, be increased by cuttings inserted in sandy soil in a cold frame during August and September.

The Mezereon thrives best in a deep, loamy soil in which there is a fair quantity of chalk or lime, and while good specimens may be seen growing in full sun, this Daphne prefers shade; indeed, in shade, the colour of the flowers is softened somewhat to an unobtrusive shade of pink, which is very effective. The plants will even tolerate the drip from trees without apparent injury. Moisture at the roots, or mulchings of well-decayed manure during the summer months are essential, otherwise the quality and quantity of blooms will be restricted.

Daphne Mezereum has several varieties, including a form which blooms in the autumn and is known as D. M. var. grandiflorum (syn. D. autumnalis). The best, however, and possibly the hardiest, is D. M. var. alba. This shrub is to be found in almost every cottage garden in Perthshire, where it withstands the severity of the Scottish winters without injury. When grown in full shade, the flowers are pure white and produced in profusion during February and March. They are succeeded by bright yellow berries, which make this shrub most attractive in early autumn. Like its parent, it is readily raised from seeds, the plants coming true. One fine plant of this variety with which I am acquainted is growing in a north border which never gets any sunshine after 9 a.m. The soil is a stiff clay containing plenty of lime rubble. This plant, which is quite ten years old, is in perfect health, and blooms profusely each spring. *H. H. C., Reading.*

ALPINE GARDEN.

SYNTHYRIS RENIFORMIS.

A FAVOURITE early-flowering plant with all who grow it is Synthyris reniformis, the best member of a small group of plants from western North America, nearly allied to Wulfenia, and belonging to that great Natural Order, Scrophulariaceae. A few species are in cultivation, and S. reniformis was introduced in 1885. The cultivation of the genus is simple, but the vague statement sometimes met with that "they require the same culture as the Veronicas" does not help much. S. reniformis grows naturally on the slopes of the western mountains of the United States, and is frequently found by the sides of streamlets. This would suggest that S. reniformis would thrive best in a moist situation, but I find it is perfectly happy on a level ledge of the rock garden, where any surplus moisture from above is sufficient to satisfy its needs in that respect. It grows well in loam, peat or leaf-soil, and sand in about equal proportions, but a little more or less of either seems immaterial. S. reniformis is now well established in the affections of rock gardeners, and when in bloom from April onwards appeals to many others because of the neat tufts of kidney-shaped leaves, above which, to a height of five or six inches, are borne the furry-looking spikes of violet flowers. It is a very free-flowering and perfectly hardy with me, and has been flowered very happily this April, although the plants had been exposed unprotected to a blizzard of wind and frost without even any snow to shield them. S. reniformis does not appear to object to either sun or shade, but drought should be avoided, and where there is a danger of this a few stones laid about the plant will be welcome.

SAXIFRAGA PETRASCHII.

WHEN we find such an authority as the late Mr. Reginald Farrer giving it as his dictum, without any reservation, that Saxifraga Petraschii "stands at the head of all white-flowered Kabschia hybrids," and that since the publication of his *English Rock Garden* no other white hybrid has appeared which has a stronger claim to this distinction, it may be taken for granted that this plant is of more than ordinary beauty, which it is, and it is universally admired by plant lovers who see it in my moraine. It is a hybrid of S. marginata and S. tombeanensis, and is not only a good grower, but free-flowering, which is not the case with all of its class.

S. Petraschii forms a tuft of small rosettes, composed of spreading leaves, narrow in form, and with acute tips and keeled on the upper surface. This tuft is of great beauty throughout the year, but when covered with the pure white flowers in spring, the aspect of the plant is truly delightful. As is the case with other plants of this type, the stems are short—only two or three inches in length—with a yellowish tint, and several—three to four, usually—of the wonderfully large, snowy-white flowers are borne on each stem. I grow it in a whinstone moraine with a little lime added.

GENTIANA VERNA.

THE glorious colour of Gentiana verna appeals to every one, and it is really amazing to see how so small a flower strikes the eye with such brilliancy as to attract even at a considerable distance. Close inspection does not detract from the impression formed a little way off, but rather heightens it, so intense is the blue, which is accentuated by the white eye which characterises the bloom before fertilisation.

The Spring Gentian is one of the most enchanting of our spring flowers, and happy is he who has established it in his garden and can enjoy its glorious flowers year after year. But—and who often does a "but" enter into our consideration of flowers ?—it is not always that success attends the efforts of the gardener to woo this charming plant, and to persuade it to dwell with him. Too frequently, G. verna disdains all his care and dwindles away, although all the stock prescriptions are tried. It remains a problem with many and even experts admit that so much depends upon the soil and other conditions that it were empiricism to dogmatise upon the question of culture. An eminent, authority suggests a compost of one part leaf-mould to two or three times as much of the coarsest sand, a sunny slope for the bed, with coarse drainage and plenty of chips; underground water in summer and "plenty of company, of not strong growth." The soil compost is easily secured, and the sloping bed with drainage also, but the underground water is not available everywhere, and few provide it. The question of company is a difficult one, as in some places even the dwarfest plants we have may act the part of the monster created by Frankenstein and destroy the object of our admiration. In practice, I think it will be found that a mulching with chips or small gravel will be equally acceptable to G. verna, although in nature it revels in the neighbourliness of its companions of the Alps and elsewhere. A top-dressing of leaf-soil and sand, and this mulch of chips, will give it an opportunity of making its growth unharassed by any fear of extinction by its enemies—drought, want of shelter for its thread-like roots, and excessive wet in winter.

All this applies to the various forms of G. verna, and one desires to mention the special beauty of G. verna var. angulosa, one of the best forms of a wondrously beautiful flower, of which there are, however, some poor examples, some thin and without substance; others small and poor in colour. The variety angulosa has none of these defects. It is large (for the species), is of grand colouring, of excellent form, and seems even more robust than most of the forms offered by the trade. Here it is growing on the level in loam, sand and leaf-soil, with the surface covered with chips. It is well supplied with clear water and thrives and flowers apace. *S. Arnott.*

THE GENUS PRIMULA.

(Continued from p. 282).

MICROLOMA (Hand.-Mazz.). Small-podded P.
(Candelabra.)

A VERY beautiful, herbaceous perennial species, with a tuft of green, egg-shaped leaves one inch to three-and-a-half inches long, broadly rounded or sub-truncate, slightly narrowed towards the base; margins sharply and densely toothed; upper surface more or less smooth, under side sprinkled with yellow meal. Flower stems one to two in number, four to eleven inches tall, slender, bearing one or two superposed umbels of two to six white blossoms, on slender stalks clothed with yellow meal. Corolla about one inch across, funnel-shaped, downy without, divided into five rounded, cleft lobes; tube more or less cylindrical, short, downy, about as long as the calyx, with a thick ring in the mouth. Flowers in July. Not in cultivation.

Grows in the shade of Rhododendron bushes in Pine forests on the mountains of the Salween-Irrawaddy Divide, in north-western Yunnan, at about 10,500 feet above sea-level.

Culture: Peat, friable loam and leaf-soil, in a cool, shady spot, should suit it.

MICROPETALA (Balf. f.). Small-petalled P.
(Muscarioides.)

A beautiful little species from the eastern Himalayas, with a short rootstock and small rosettes of greyish leaves about two inches long, with oblong-oval, blunt or rounded blades gradually tapering to a narrowly-winged stalk, expanded at the base into a long, narrow sheath; margins entire, or edged with obscure, rounded teeth and fringed with minute hairs; both surfaces covered with very minute down. Flower stem about four inches tall, downy, green, bearing a head of blue or violet, deflexed blossoms. Corolla about three-eighths-of-an-inch long, somewhat fleshy, narrowly cup-shaped, with five overlapping, egg-shaped, slightly notched lobes; tube cylindrical, dilated upwards, about a quarter-of-an-inch long. Flowers in June.

Grows in damp, somewhat shady, rocky places in short turf, in Bhutan, in the eastern Himalayas, in Champa Pumthang, also on Nam La in south-eastern Tibet, at 15,000 to 16,000 feet above sea-level.

Culture: As for P. metria.

MICROSTACHYS (Balf. f.). Stachys P.
(Malvacea.)

A pretty, slender species with a sparse tuft of somewhat membranous leaves, with broadly-oblong or oval blades, three-quarters to one-and-a-quarter inch long, rounded at the tip, broadly wedge-shaped or sub-rotund at the base, borne on distinct, minutely downy stalks; margins rather deeply cut into rounded lobes; both surfaces covered with minute down. Flower stem slender, three to eight inches tall, bearing an elongated raceme of three to twelve rose-coloured, yellow-eyed blossoms, on stalks barely one-eighth-of-an-inch long. Corolla more or less flat, about half- to three-quarters-of-an-inch across, divided into five broadly wedge-shaped, deeply notched lobes; tube narrowly cylindrical, about half-an-inch long. Flowers in July and August.

Grows in open, stony pastures on the Mekong-Yangtze Divide, in Yunnan, western China, at 9,000 to 10,000 feet above sea-level.

Culture: As for P. blattariformis.

MINIMA (Linn.). Least P.
(Auricula-Chamaecallis.)

A very beautiful, minute species, forming mats of dark green foliage. The broadly or narrowly wedge-shaped, abruptly truncate leaves are from half- to one inch long, the truncate portion being furnished with sharp teeth; both surfaces are more or less smooth. Flower stem from almost obsolete to one inch long, bearing one to three bright rose-pink blossoms, with white throat, on very short stalks. Corolla funnel-shaped at the base, flattening upwards, three-quarters- to one-and-a-quarter inch across, lobes broadly heart-shaped, bifid; tube longer than the calyx. Introduced in 1819. (Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913).

Grows in wide lawns on the alpine moorlands of limestone or granite, ranging from central and southern Austria, through the Balkan Peninsula, to Bulgaria, reaching an elevation of 9,000 feet above sea-level.

Var. alba (Opiz.). Flowers white; Bohemia.

Var. caulescens (Wimm.). Flower stems twice as long as the leaves, flowers small, rose; Riesengebirge.

Var. fimbriata (Tausch.). Flowers with shallowly fringed lobes; Riesengebirge.

Culture: Good fibrous peat and loam, mixed with limestone chips, and kept reasonably moist when the plant is in growth fulfil its requirements; it should be planted among very dwarf growing grasses or other dwarf alpine plants, in an open situation.

MINOR (Balf. f.). Small P.
(Nivales.)

A pretty, fibrous-rooted perennial species retaining much of the dried remains of previous seasons' foliage. The smooth, oblong-spathulate, blunt, somewhat thick leaves are about two inches long and taper to a narrowly-winged stalk dilated at the base into a sheath; margins recurved and furnished with minute, rounded teeth; upper surface sparsely covered with yellow meal, underside densely so with the exception of the central nerve and stalk. Flower stem two to three inches tall, purplish and coated with yellow meal towards the tip; the blossoms, which number about eight, are borne in an umbel of purple, mealy stalks sub-tended by purple bracts. Corolla about three-quarters-of-an-inch across, violet, with a white eye; segments flat, narrowly oblong or elliptic, entire or very obscurely toothed; tube mealy outside, cylindrical below, dilated upwards with a conspicuous five-lobed ring in its throat. Flowers in May.

Grows in rather dry situations on open mountain slopes, in the shade of rocks near Atuntsu, in Yunnan, western China, at 13,000 to 14,000 feet above sea-level.

Culture: Good fibrous loam and leaf-soil, in a well-drained spot, are indicated. *A. W. Darnell.*

(To be continued).

PLANTS NEW OR NOTEWORTHY.

MERTENSIA MOLTKIOIDES, C. B. CLARKE.

THE American species of Mertensia furnish the flower border with strong-growing, handsome plants from one-and-a-half to three feet in height, while those from the Himalayas are dwarf alpines. All are plants of the margins of woods and are never seen at their best when exposed to full sun; they delight in moist, shady situations, and with abundance of leaf-soil to grow in.

I found them far easier to cultivate in the north of Scotland than in the south. The Indian species are, perhaps, easier to manage than the American, and so far as M. moltkioides is concerned, this can be confidently stated, as it has proved one of the most accommodating plants, impervious to frost or cold, being in full flower in several gardens during April of the present year.

It dislikes pots and frames, and has formed within sixteen months from sowing, fine clumps which have all flowered freely in the open border.

So far, no reference to this species having been in cultivation has been traced; its nearest ally is M. elongata, but M. moltkioides (Fig. 161, p. 323), is a more vigorous plant, and likely to remain in gardens. When in flower, it is but three inches in height, of an exquisite shade of blue, leaves oblong or elliptic, two inches in length, and hairy. It is an alpine of great beauty and promise; native of Kashmir, in the margins of forests north of Hayan Pass, at 11,000 feet.

It received the R.H.S. Award of Merit on April 23.

The genus Mertensia comprises about forty species, some of which would be fine acquisitions to our gardens. Our own native M. maritima is well worth cultivating.

TROLLIUS ACAULIS, LINDL.

THIS species was figured and described by Lindley in Volume XXIX of the *Bot. Mag.*, t. 32 (1843). It has occasionally found its way into trade catalogues but has remained a very scarce plant. Farrer describes it as a treasure from the high Himalayas requiring the underground-watered moraine bed; this, however, does not seem necessary, for at the moment the plant is flowering without any protection or special treatment and only at an age of sixteen months from seed-sowing.

This diminutive species, only a few inches high, carries flowers over two inches across, of a good yellow, which open out widely after the fashion of T. patulus. The plants, being young, are bearing only a single blossom each, but this gives a good idea of what they might be capable of when established and grown into good clumps.

T. acaulis is also figured in two recent works on the Kashmir flora, Blatter's *Beautiful Flowers of Kashmir*, and Coventry's *Wild Flowers of Kashmir*, and is described as a dwarf alpine perennial with unbranched stem, radical leaves deeply cut into fine lobes; flowers large and showy; the whole plant only from three to six inches in height, but the flower stem lengthening when going to seed.

It is the only species in Kashmir, and is a common plant there at from 10,000 to 13,000 feet, and abundant on Apharwat.

Trollius acaulis flowers in Kashmir during June and July, but in cultivation it promises to be much earlier.

CALTHA PALUSTRIS, LINN. VAR. ALBA, HOOK.

OUR native Caltha palustris when seen luxuriating in a wet meadow or wood, is a handsome and imposing plant both in foliage and flower. The variety under notice is a white-flowered counterpart of our native species, and has already been honoured with the R.H.S. Award of Merit, when exhibited by Mrs. Botfield in March, 1927. The plant was shown in a pot and was much admired.

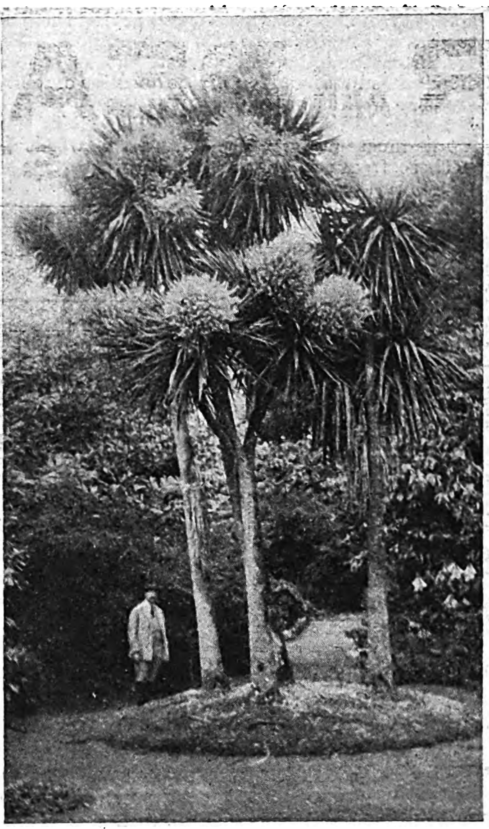

FIG. 162.—LOGAN: CORDYLINE AUSTRALIS.

(see p. 329).

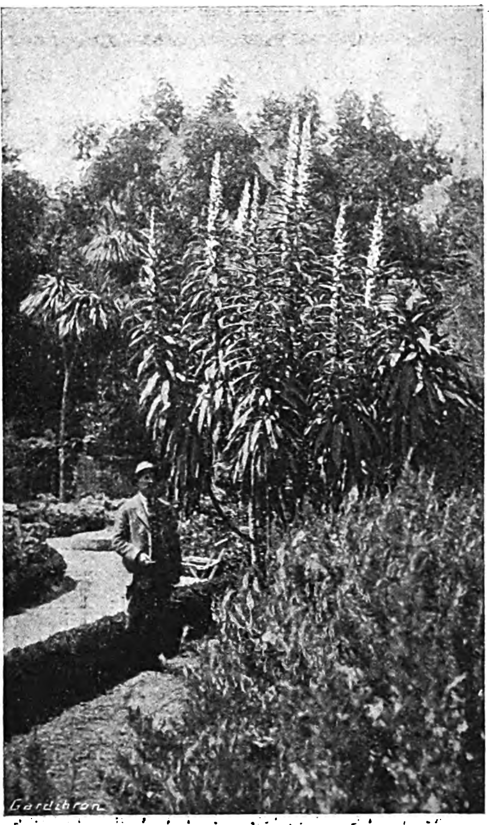

FIG. 163.—LOGAN: ECHIUM PININANA.

(see p. 329).

At present, I have the plant flowering in the open, where it is particularly attractive. Although still in the young state, it is bearing large, pure white flowers nearly two inches in diameter, which are brightened by the cluster of rich yellow stamens. It promises to be a healthy, happy plant, a worthy companion to our native species, and requiring no different treatment.

This variety of Caltha is a native of Kashmir, and is figured in Coventry's *Wild Flowers of Kashmir*, Vol. I, t. 6. I am informed that it is plentiful at Gulmarg, in wet, marshy ground, at 11,000 feet elevation.

The above three plants all formed part of a large collection of seeds, plants and bulbs sent over in the autumn of 1927 by His Highness The Maharajah of Kashmir for the decoration of the Royal Parks and Gardens.

ASTRAGALUS UTAHENSIS, TORR. AND GRAY.

IT requires some courage and a great amount of knowledge to write anything about a genus which comprises about 1,500 species. Out of this great number Bailey describes only ten in his *Cyclopedia of Gardening*, and Nicholson about thirty in his *Dictionary of Gardening*.

Representatives of the genus seem to be found all over the world and include dwarf alpine species, sub-shrubs, and herbaceous kinds. That there must be many desirable species in so large a genus is certain, but they are very rarely seen in gardens or referred to in current gardening literature. It is, no doubt, among the dwarf species that there will be found those most worthy of being cultivated, and the American members of the genus would be most suitable for our climate.

Seeds of Astragalus utahensis were received in the autumn of 1926 from an enthusiastic plantsman of Salt Lake City, and under the skilful treatment of Mr. C. T. Musgrave plants grew to perfection, and were exhibited by him at the R.H.S. meeting of April 23 (Fig. 160, p. 321). This species is described in most of the American manuals, but in Rydberg's *Flora of the Rocky Mountains* the genus has been so divided that a large number of new and strange generic names appear and Astragalus utahensis is now called Xylophacos utahensis.

It may be briefly described as a dwarf perennial plant with divided leaves, each with from twelve to eighteen white leaflets. The flower stems are about eight inches high, ending in a cluster of from six to ten flowers of a pleasing rose-purple shade. The whole plant is delicately harmonious and beautiful.

This Astragalus is quite hardy, but of slow growth in its early stages. Mr. Musgrave says it is even more striking during its summer state, when it forms a lovely mound of almost white foliage. *T. Hay, Hyde Park.*

BOG AND WATER GARDEN.

CARDAMINES.

I AM glad to see that your contributor, J., (p. 246) has written in favour of Cardamine macrophylla, and has referred to some others of the genus. C. macrophylla is a much better plant than is generally supposed, but it requires to be carefully planted on account of its colour. By some mischance, C. macrophylla was planted next a group of plants of Saxifraga decipiens var. Red Admiral, and as the two were in bloom at the same time the colour effect was far from pleasing. Now the Cardamine has been relegated to a moist corner devoted mainly to moisture-loving Primulas, and there, kept within bounds, I expect it to do well and be very effective.

I observe that the same contributor states that the pure white double variety of the Lady's Smock, C. pratensis, is "unheard of now." It is a plant I once had, but am desirous of getting again, although, as a garden plant for effect, the double lilac one is superior. I note also his remark concerning C. trifolia, that it "misses being a front-rank plant." This is true, but it is so early and so oblivious to bad weather that it deserves a place where there is plenty of room. Many years ago, I used to wonder at the high opinion held of it by a keen amateur of my acquaintance, but after growing it, I was not surprised. At that time we had a much smaller choice of early flowers, and this plant was sometimes very useful for spring effect. *S. Arnott.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

GRANT THORBURN.

IN the records of that great army of Scotchmen who have left their native land to carry civilisation to less favoured countries, the name of Grant Thorburn, New York's pioneer seedsman, should surely be enrolled.

His life and work are, fortunately, preserved in a small autobiographical volume published in London in 1834, which is entitled *Forty Years' Residence in America; or the Doctrine of a Particular Providence Exemplified in the Life of Grant Thornburn (The original Lawrie Todd), Seedsman, New York.* Apart from its general interest as a picture of New York in the beginning of the last century, it preserves for us a record of the founding of the seed trade in New York that is of special value.

Thorburn was a typical Scotchman of his day, and he faced his journey to the unknown country with a dour courage, upheld by the realisation that Providence had him in her special charge.

His father, "a stiff Scotch Presbyterian" and by trade a nail-maker at Dalkeith, near Edinburgh, brought up his son to his craft, but at the age of twenty-one, Grant Thorburn and his brother set sail for America on April 13, 1794, and on June 16 they arrived in the harbour of New York with three cents only between them and starvation. Employment in his own trade was, however, found at once, and for some time continued. The day of the machine was, however, approaching, and before long the hand-making of nails went the way of so many other handicrafts.

Two years' work had enabled the brothers to lay by a hundred dollars, with which they stocked a small cutlery store, but as the stock made but a poor show, some bricks were secured and covered with paper, and a spoon or fork attached to each on the outside, thus creating an appearance of great resources. From this occupation, Thorburn passed into the grocery business, and it was this, curiously enough, which led him into the seed trade. Referring to the year 1801, he states: "About this time the ladies in New York were beginning to show their taste for flowers, and it was customary to sell the empty flower pots in the grocery stores; these articles comprised part of my stock."

From empty flower pots to full ones was an easy step, and finding a man selling plants in the "Fly Market, which then stood in the foot of Maiden Lane," he purchased some "Rose Geraniums," evidently one of the scented-leaved species, from his description, and potted them up to draw attention to his flower pots. The venture attracted some interest, but as several of his customers lived far off, the question of selling seeds as well as plants arose.

The small beginning of the seed trade in New York must be given in his own words:—"These frequent inquiries at length set me to thinking, that if I could get seeds, I would be able to sell them; but here lay the difficulty, as no one sold seeds in New York, no one of the farmers or gardeners saved more than what they wanted for their own use; there being no market for an overplus. In this dilemma, I told my situation to George Inglis, the man from whom I had always bought the plants in the Fly Market. He said he was now raising seeds, with the intention of selling them next spring along with his plants in the market; but if I would take his seeds, he would quit the market, and stay at home and raise plants and seeds for me to sell. A bargain was immediately struck; I purchased his stock of seeds, amounting to *fifteen dollars*; and thus commenced a business on September 17, 1805, that already is the most extensive of the sort in the United States.

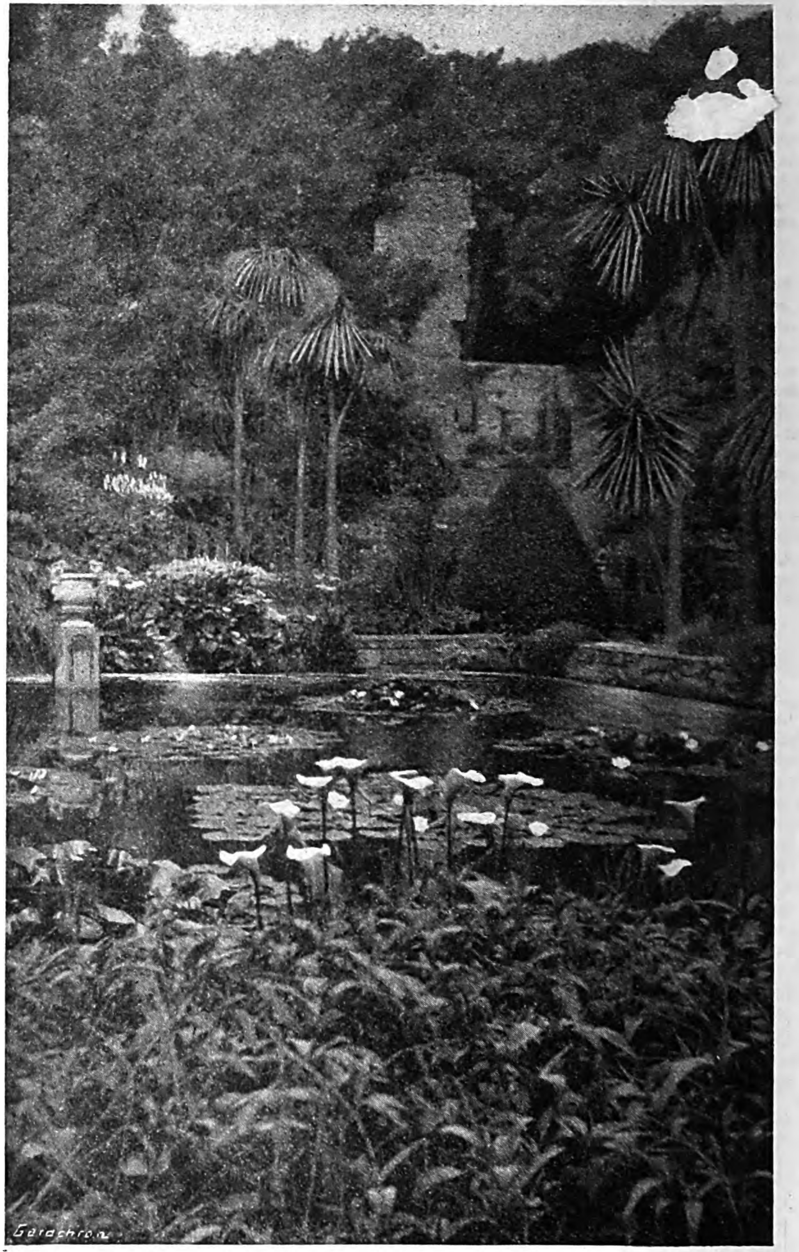

FIG. 164.—LOGAN: RICHARDIAS, NYMPHAEAS AND CORDYLINES.

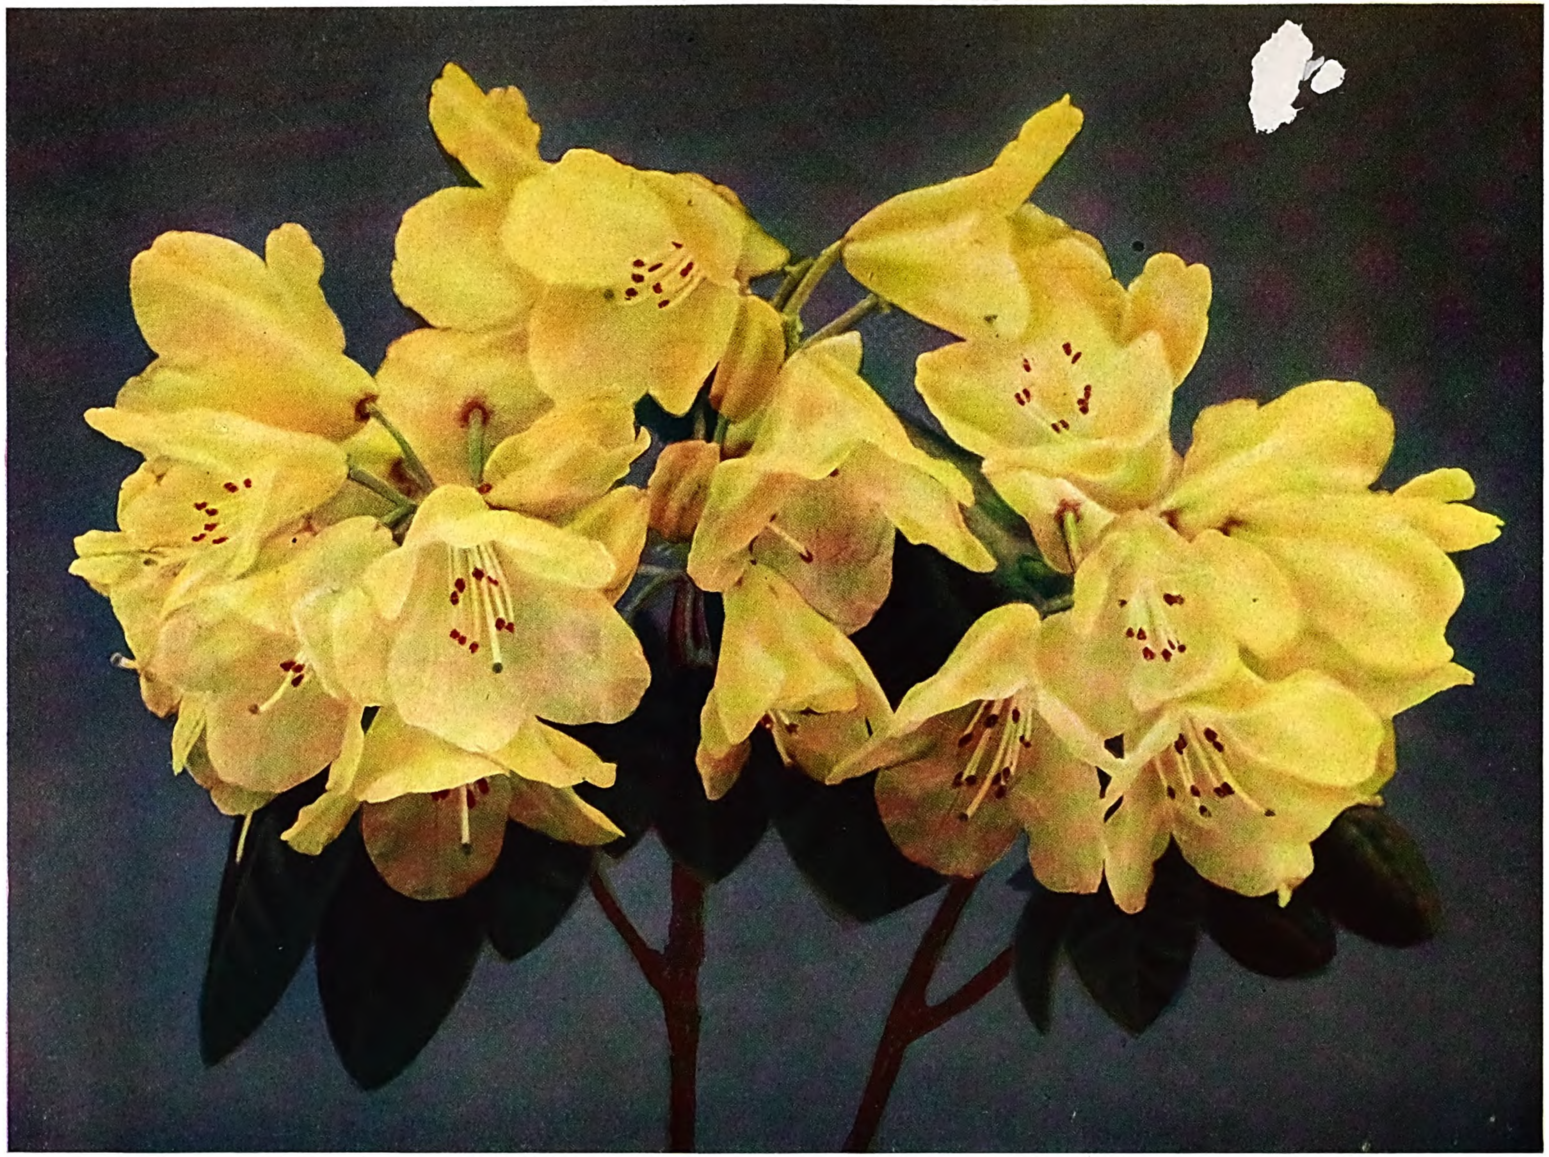
"I now advertised in the papers of the day garden seeds. In a short time my small stock was all sold out; I knew not where to replace them. In this difficulty a friend* stepped into the store, and introduced me to his friend, Mr. Morgan, just arrived from London, having a small invoice of garden seeds, which he was willing to sell at a small advance. A bargain was soon struck, for the invoice contained the very articles I was daily asked for, and knew not where to obtain. Next day, on opening the casks, I found a catalogue of seeds for sale by William Malcolm and Co., London; this was at that time a prize to me, for never before this had I seen a seed catalogue. This catalogue had noted on the margin the time of sowing—a thing I was totally ignorant of. Having now a plan, I published a catalogue of my own, and, with the assistance of my friend the gardener at Brooklyn, adapted the time to suit our own climate; so that now, when my customers asked when such and such seeds ought to be sown, I was able to give the necessary information. Next fall, I sent a small remittance with an order to Mr. M. The seeds arrived in good season, and, with the seeds raised by my friend at Brooklyn, composed a good assortment to commence business in the spring. The seeds

---

* T. L. Rich, for a long time a respectable merchant-tailor in Wall Street.

Supplement to "The GARDENERS' CHRONICLE.'



RHODODENDRON CAMPYLOCARPUM.

I had imported and got raised here, proving very good, my sales increased beyond what my friend could supply; and some of the market gardeners, supposing they might be able to sell me seeds, had this year raised seeds for that purpose. Having no other resource, I was fain to purchase such as were offered, and being a mechanic by profession, and alike ignorant of seeds and gardening, I had long to struggle with the impositions of unprincipled seed-raisers, they often selling me spurious seeds, and asserting they were of the most genuine quality.

"In 1808, when all intercourse between America and Britain was suspended, and we were therefore prevented from importing such seeds as are necessary in our business, I was advised by my friends to attempt the raising of them myself. I was drawn into this business much against my own inclination and better judgment, as you will see in the sequel.

"A few years previous, a gardener from England by the name of Thornly, purchased about seven acres of land near Newark Bridge, which he improved as a kitchen garden, and for raising a few seeds; but failing of success, and getting in debt, he absconded."

For various reasons which need not be detailed here, things for a time went wrong for Thorburn, and he had to take refuge in bankruptcy, to which it seems, in those days, a short period in gaol was a necessary preliminary. But, as stated previously, success finally rewarded his labours, and the business grew to be of importance.

Thorburn's little book, apart from its horticultural interest, deserves reading for its own sake. His meetings with Thomas Paine and William Cobbett have the very ring of truth and reveal him as a real "character." Small wonder that Thomas Galt should have seen his value as copy and as "Lawrie Todd" introduced him into his novel bearing that name, "perhaps a little curtailed in the fair proportion of those singularities which constitute so much of Mr. Thorburn's right to distinction."

Thorburn himself wielded an active pen, and before his death no less than six books were published by him, and if they are all as good as his autobiography they should be well worth reading.

A ripe, salty character was New York's first seedsman (see p. 320), with that good opinion of himself without which little good work is done. A hero where heroism was needed, matter of fact in worldly matters, courageous—as witness his friendship for Thomas Paine—no fit companion for an elder of the church—his voice speaks to us with a sincerity which makes him alive and near to us across a century of time. *E. A. B.*

LOGAN.

GARDENERS speak of Logan, the residence of K. McDouall, Esq., with bated breath, as they would speak of the garden of the Hesperides, or even the Garden of Eden. Yet it is less mythical than either, although scarcely less legendary; nay, the writer has actually seen it.

Most of us firmly believe that it grows colder as we travel northwards, and that the farther south we go, the nearer we get to the tropics; therefore, to reach a mild climate, we ought to travel southwards, or, at any rate, south-west. Yet at Logan, which, by the way, is in Scotland, there are probably more sub-tropical plants growing than in any other garden in the United Kingdom. It is necessary, then, to correct our ideas, and we are probably justified in drawing two conclusions: (1) That the climate of England differs sharply east and west of a certain meridian, rather than north and south of a standard parallel, although the change is doubtless progressive; and (2) that perhaps, after all, water is more important to plants even than temperature.

True, Logan, being situated near the end of a narrow isthmus, is immune from frost; nevertheless, the positive good outweighs the negative evil. Nor is it only the soil conditions which count; atmospheric conditions are equally important. Mr. McDouall* has told us that at Logan the air is sometimes visibly full of salt spray, and adds that it does the plants no harm. Rather may we suspect that it does them solid good. One of the most memorable features of this audacious garden is the ease with which Tree Lobelias from Ruwenzori, Tree Ferns from New Zealand (Fig. 166), big-leafed Rhododendrons, and high alpines, such as Nomocharis and Cremanthodium, thrive—all plants which flourish in a highly saturated atmosphere. May we not reasonably infer that salt, being hygroscopic, holds the aqueous vapour in the atmosphere, and is so far beneficial to these very particular plants? There can, indeed, be little doubt that so soon as the vapour tension sinks below a certain point—and that a high one—this type of plant wilts, and that if the treatment is prolonged, the sickness is mortal; and it is for this reason that alpine plants from high, tropical mountains may hardly ever be persuaded to grow in Britain.

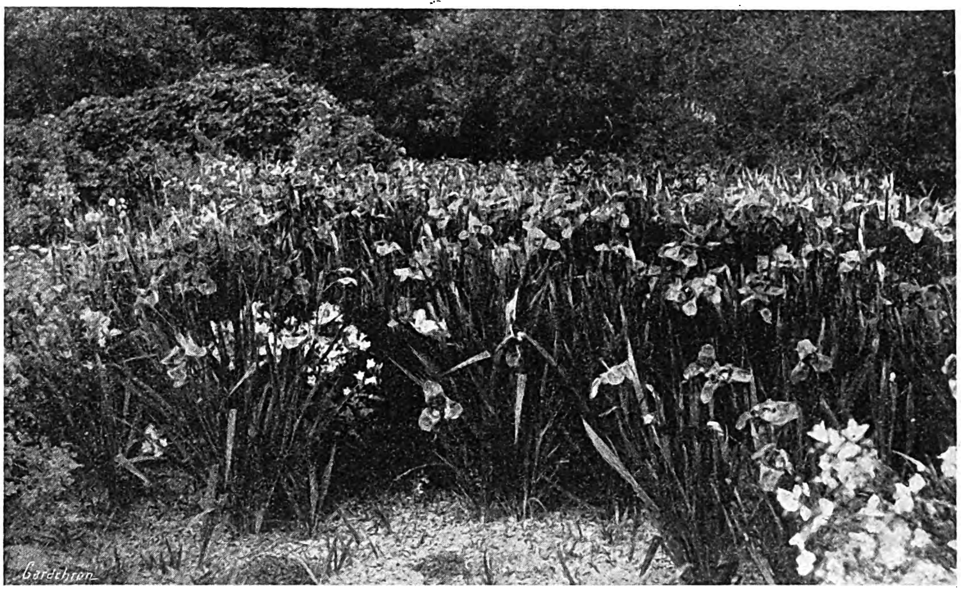


FIG. 165.—LOGAN: A BIG GROUP OF TIGRIDIAS.

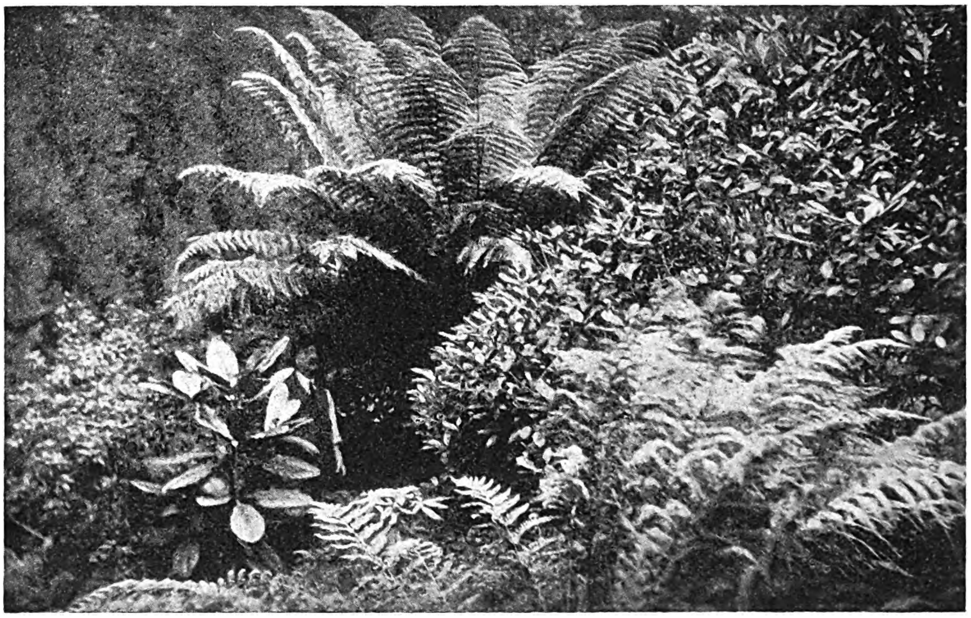

FIG. 166.—LOGAN: DICKSONIA ANTARCTICA.

And now to the results. The garden itself is a maze of interlocking parts, gardens within a garden, not so formal as a Chinese garden, where prim court opens into prim court, nor so vague and haphazard as the wilderness, with its bulging disorder, but very pleasing in its easy transition. We feel all the time that the owners have worked—and how they must have worked!—on the principle of "take care of the plants, and the garden will take care of itself." High stone walls, and a wealth of fine trees, helped by the slant of the land, protect the garden from the inrush of the south-west gales. A cross wall of Beech, twenty feet high and ten feet thick, forms a Babylonian bulkhead behind which, on a slope revetted with bricks of peat, grow many rare plants. Here all the Lilies of the field grow waist deep in seas of dwarf Rhododendrons—R. repens, R. calostrotum, R. campylogynum, and R. cyclium; and here, too, grow in sheaves and clumps, the star-spangled, pink-cheeked flowers of Nomocharis pardanthina. A number of large-leafed rosettes, with a pool of water in the centre of each, attract attention; they are young plants of Lobelia Deckenii, which had not yet flowered, but which in a few

---

**Journal* of the Royal Horticultural Society, Jan., 1927.

years may shoot up their enormous spikes before dying. If these plants from the equatorial Alps can grow here, why not the New Guinea Rhododendrons, the weird and wonderful R. von Roemeri, or the lovely R. de Freesianum?

There are stately Poppyworts here, too, Meconopsis paniculata, and the blue and gold M. Wallichii, M. Prattii, M. Baileyi and M. simplicifolia; and where Tree Ferns are sowing themselves on a peat wall, Primula bella shines like a remote violet star. Cyananthus, Gentiana sino-ornata, and G. Farreri are autumn-flowering jewels.

While we wander amid the clash of colour and beauty of form we find ourselves insensibly in a new world. The scene has changed, that is all. Here a stream prattles over the living rock, working down from the tank above to the woodland below. On the rocks are crusts of Lysimachia Nummularia, Sedums, and a new annual Calceolaria with softly luminous, yellow flowers; not far away, a clump of glaucous-leafed Eschscholzia with sherry-brown flowers, and Fuchsia serratifolia, compel admiration.

We wander on in a peaceful trance, as colour succeeds colour and form changes. Always the scene changes, melting swiftly, yet insensibly, from the aggressive colour note of the cold north zone, to the dominant shape cult of the sunny south. There is a lawn here, flanked by two large bushes of Desfontainea spinosa, and at the end, a great tank, mantled with the floating leaves of hybrid Nymphaeas (Fig. 164), among which bob up the vivid, saucer-shaped flowers. The tank is surrounded by a balustrade, with large stone urns at intervals, over which lean down to the water Bamboos and other gracious trees, whose reflections fill up the spaces between the leafy rafts. A blaze of flaming gamboge radiates from a thicket of Calceolaria integrifolia, filling the scene with the divine glory of colour, and then, lifting our eyes, we see the crowned heads of Cordyline australis (Fig. 162), part of a great avenue, now sixteen years old, and are instantly translated to the pagan splendour of form. A tank of Nymphaea stellata (Fig. 168) is also a fine feature.

There was once a high glasshouse beyond the tank, but the glass roof has been removed, leaving only the wall, against which grows the yellow-flowered form of Datura sanguinea; farther along are Cobaea scandens, the flowers of which open green, then change to purple; and the silvery-green Wattle, Acacia Baileyana. There is also a huge, overflowing bush of Calceolaria violacea (Fig. 167), half smothered beneath the scarlet trappings of Tropaeolum speciosum.

A flight of stone terraces, backed by a lofty wall which culminates in the ruins of an ancient castle, is one of the most notable features of the garden. The terraced walls and gravelled ledges are draped with sonorously-coloured Mesembryanthemums, magenta and sherry-brown, and pink and brazen yellow; they hang in lurid festoons, or erupt vividly from the crevices. There are also Aloes and Saxifrages, and Rock Roses. The high wall behind is covered with climbing plants, including Aristolochia Sipho, Solanum jasminoides, and the yellow Bottle-brush, Metrosideros tomentosa.

Among an astonishing variety and profusion of shrubs scattered through the flowery courts, where their many-figured shadows cast a pleasant twilight over the glowing beds, are Azara microphylla, Abutilon vitifolium, Drimys Winteri, over twenty feet high, Tricuspidaria lanceolata almost as big, a huge plant of the evergreen Euphorbia mellifera, ten feet high and forty-eight feet round, Rosa Moyesii, Berberis Prattii, Genista fragrans, Eupatorium Weinmannianum, Myrtus Luma, and Celmisia grandiflora.

In an open arena in the more herbaceous part of the garden, an ingenious and successful experiment has been tried. A bed of deep, cool loam has been top-dressed for an inch or more with stone chips, on which one may walk about among the plants. These last, comprising gaudy Tigridias, Lilies, and especially clumps of Dierama pulcherrimum, are given plenty of room. As to the last-named, never has this oddly beautiful Cape plant been seen to better advantage. It grows six or eight feet high, and its swinging files of rosy-purple, Foxglove-shaped bells, supported by invisible wires, and sensitive to every breath, seem to float in the air. Yet, however hard it blows, the tall reeds merely bow to the gale, continuing to flutter their flowers like purple bunting. As for the spotted Tigridias, there is a clump of them ten feet across (Fig. 165), raised from seeds which germinate freely all around.

The double avenue of Cordyline australis reveals the sheer beauty of outline, and there is also a short avenue of Trachycarpus excelsa. Clianthus puniceus has climbed to the top of a Cordyline, whence it hangs in looped curtains. The Eucalyptus trees (E. Globulus) have reached a great size, and near the top of the garden are the giant Echiums (E. Pininana), from the Canaries, via the Scilly Isles. These plants, seventeen feet high—seven feet of flower spike on ten feet of stem—have outgrown the highest wall (Fig. 163).

Senecio scandens has arisen and smothered an Apple tree, whole-heartedly, and Lonicera tragophylla, with large but scentless, yellow flowers, and L. villosa, have done the same. Mitraria coccinea, beaded with translucent, scarlet tubes, hugs a wall. There are several Fuchsias and Olearias. Fuchsia serratifolia is a fine bush with strangely coloured flowers, and there are good specimens of F. excorticata. Among Olearias are O. semidentata, O. chathamica, O. Colensoi and O. virgata, with tiny leaves on long, whip-like shoots.

Round the house are massed trees alternating with tilted lawns and a long, varied avenue, in spring aflame with Rhododendron blossom, leading down to the high road. The trees are old and big, casting benign shadows, rustling and sighing always for their lost youth, and anon creaking and groaning stiffly in the wind. Pinus insignis and P. excelsa are here, and there is a fine specimen of Sciadopitys verticillata, the Japanese Umbrella Pine; another very beautiful Japanese Conifer is Larix Kaempferi.

Rhododendron Russellianum forms bushes as big as cottages, thirty feet high, and flowers year after year in a flood of crimson. There are many other species and hybrids near the house, including R. Luscombei and R. campylocarpum.

The inner circle of the garden is entirely surrounded by woods, with the sea close up on either flank. From the house itself we look out across a green lawn, fringed with the exotic shape of Cordyline rising up above an amorphous thicket, the ground all tilted cunningly awry, to a lake, just beyond which is the sea, backed by the blue hills of Kirkcudbright across the bay. On the other side, the woods are so thick and the slope so steep, that only the booming of the waves along the rock-bound coast tells of the sea's near presence; until on a day of storm, the salt spray comes winging over.

It is a delightful walk down the glen to the coast, through delicious woods, the narrow path thickly lined on both sides with Primula japonica and P. pulverulenta; and in clearings of the forest are beds of Rhododendrons, especially R. sino-grande, R. Kyawi and R. cyclium. But the main Rhododendron wood is nearer the garden, and contains hundreds of sturdy plants, including R. Keysii, R. decorum, R. Aucklandii, R. arboreum, R. argenteum, R. Falconeri, R. oreotrephes, R. Souliei, R. calophytum, R. arizelum, R. sutchuenense, R. glaucum, R. Hodgsoni, R. niveum, R. giganteum, R. Ungernii, R. lutescens, R. Hookeri, R. Maddeni, R. camelliaeflorum, and others; with splendid Tree Ferns (Dicksonia antarctica), Maples, Beech, and other shelter trees. These all grow on a steep slope facing the east, and therefore with their backs to the wind.

The herbaceous borders are dappled, undulating seas of colour. Here form is merged in a vague unity of purpose, to which all plants contribute. Thalictrum aquilegifolium and T. glaucum, bursting with clouds of fluffy yellow flowers; bands of Viscaria, like many-coloured buoys bobbing on a sage-green sea; a rainbow of Sweet Peas stirring up through the branches of dead trees to a height of ten or twelve feet; giant Delphiniums in close order; and bold clumps of the dusky scarlet Monarda didyma, which is stated to be visited by humming birds in its native America; these, with Phlox, Sweet William, Campanulas, and many other flowers, help to weave a spell over Logan. Such herbaceous graciousness, in the midst of solemn trees, enclosed by hedges of Escallonia and sheltered by the mighty wall of Beech, which forms a bulwark against the fury of the gale, is as charming as it is unexpected.

In the midst of this lively livery, we feel that the more humble and passing plants have full scope as attendants in the pageant of the trees. They act as nimble foils to display to better advantage the wonder of form in the vegetable kingdom, as best illustrated by trees. And the deep glory of Logan can never be fully appreciated unless this underlying idea of perfect outline is grasped. It appears in the garden as a whole, with its overlapping parts, smooth unexpectedness, and balanced contrast; in the groups of trees, the avenues, and cambered lawns bound with bushes; and in each individual plant, placed just where its effect will be best felt. When the surrounding woods are incandescent with the fire of Rhododendrons, in May, no doubt stark colour strikes the dominant note; when the woodland paths glow with tens of thousands of Primulas, for a time, at least, form is forgotten, and we bask in the sheer luxury of sensuous colour. But, mostly, Logan is a garden of whimsical shapes, which loom imperiously over all, gigantic and all-powerful; shapes now firm and curtly angular, now elusive and melting into soft roundnesses, ever changing like a transformation scene as the ground dips and rolls, or as we wander, wondering, by a winding path beneath the shadow of noble trees.

Nor is all this the result of chance, a hazard which has come right. Rather does it spring from a superb devotion to the welfare of plants, unrivalled skill and knowledge, and a worship of beauty on the part of the owners.

Wonderful as are the individual plants, their combination which has so completely earned the title of garden, rather than collection, is even more wonderful; so that to give mere names to these hosts of nature, growing here in perfection, seems perilously like sacrilege.

F. K. W.

NOTICE OF BOOK.

Annuals.

In the work on Annuals,* we have the third book of the series of gardening manuals published by the well-known *Gartenschönheit* firm, of Berlin, and the volume, first published in 1924, now appears in its second edition. The historical matter with which the volume opens, from the year 812 to the present day, is of especial interest, and the illustrations, culled from ancient herbals, show clearly the types cultivated many centuries ago. The subsequent matter is arranged alphabetically under the titles of the various species, and here a few cross references might be of advantage; for instance, Cacalia is found under "Emilia" and not under "C" at all. The cultural directions are clear and full, and many readers will appreciate the section on planning and planting, showing how annuals may best be utilised in all kinds of positions, although illustrations of some smaller gardens might well have been included—those shown are all of the larger size, and even include public parks.

It will be a surprise to a good many town-dwellers to learn how many hardy annuals may be successfully cultivated in window-boxes and pots. In Germany, a favourite window-box plant is the Petunia, which is excellently grown on many a town window-sill, and might with advantage be made more popular in this country in place of the ubiquitous Pelargonium.

There are a number of coloured plates of somewhat mixed merit, and some very useful alphabetical lists of the different annuals, indicating times of sowing, periods of flowering, and respective heights and colours—in fact, all the material required for the guidance of even the most inexperienced in growing annuals for various purposes,—provided he can read German.

**Einjahrsblumen*, by Paul Kache and Camillo Schneider; Berlin, Verlag der *Gartenschönheit*; price, bound, M.12, paper, M.9·50.

NOTES FROM EDINBURGH.

DURING April cold east winds have had a very drying effect on light soils. Little or no rain fell during the first part of the month and many plants felt the need of the accustomed April showers.

The temperature generally was low, but in spite of the adverse conditions, signs of growth are apparent everywhere, and early-flowering plants are making a very satisfactory show. Trees and shrubs are rapidly changing their dormant and lifeless appearance, and in addition quite a number are flowering beautifully. The green tints of the Betula and Acer families have been evident for some time—these being the first trees to welcome spring. Early frosts and cold spells have had no bad effects on the Prunus family, which is represented by P. cerasifera, P. Armeniaca, P. tomentosa and varieties in full flower. Prominent among the early-flowering shrubs are Forsythia europaea, F. suspensa, F. intermedia and F. i. var. spectabilis. The common Flowering Currant, too, is not without its charm at this time, and such species as Ribes sanguineum, with its varieties splendens and albidum, favour us with much beauty. The evergreen Osmanthus Delavayi, from Yunnan, escaped the frost which so often disfigures its beautiful white flowers. Cydonia japonica and its var. atropurpurea are aflame with brilliant flowers which show themselves proudly, although they nestle closely among the young green foliage against a south wall.

Early Rhododendrons are now a picture of beauty and especially attractive are those in the rock garden with, in some cases, backgrounds of stone. The pink R. ciliatum, on a lofty mound, overlooks its blue-coloured companion R. intricatum. R. Metternichii at the entrance to a deep valley, is ablaze with rich, rose-pink flowers. A large group of well-shaped R. racemosum is in full bloom, and very effective on the side of a mound close to the main path. This group is a special feature and remarkably attractive. Single specimens of R. ravum and R. Keiskii are bedecked in countless flowers. The former is of a beautiful pink shade, while the latter is of a delicate, pleasing, yellow colour. R. nivale is admired for its tiny, purplish-blue flowers and very dwarf, compact habit. R. impeditum has lost none of its charm as a dwarf species, and the small, purplish-blue flowers seem more numerous than the tiny leaves, so thickly are they crowded on the branches. R. sanguineum and R. repens do justice to their section and are commended for brilliance of colour and good rock garden habit. Other species, such as R. neriiflorum and R. rubiginosum, may be seen from a great distance because of their striking colours, the former having deep crimson flowers, while the latter is of a very charming shade of pink.

The American Pieris floribunda, with racemes of white flowers not unlike spikes of Lily-of-the-Valley, is somewhat attractive, and the flowers are shown to advantage by the background of dark green foliage. Other species of this genus, P. Forrestii and P. taiwanensis, are very handsome plants, and are in full flower under glass. In the same Order, Arctostaphylos Standfordiana has been covered with very pretty, white, drooping flowers. It is a remarkably attractive species, and when the blooms drop they lie around in countless numbers just like so many small hail-stones which have fallen after a winter shower.

Alpine plants are making good progress after the severe test of winter. Bulbous spring flowers are much in evidence and are represented by species of Muscari, Brodiaea and Scilla. All play their part in the colour scheme and, although common, cannot be omitted from the collection. The first to flower in the Meconopsis group is M. integrifolia var. brevistyla. Many plants on the south side of the rock garden have produced some fine, large, yellow flowers. Very little damage to this species was done by the severe winter frosts, but others, such as M. paniculata and M. superba, suffered much. The Primula family is represented at present by many good species and varieties. Among the best are P. rosea, P. minima, P. denticulata, P. frondosa, and P. The Jewel, while under glass, in the alpine house, P. Forrestii and P. Dubernardiana grow and flower side by side on a rocky ledge.

The dwarf Armeria caespitosa attracts much attention owing to its position high up in the horse shoe mound of the rock garden. Countless pink flowers cover each individual plant, and the whole makes a complete carpet. Anemone Pulsatilla and varieties, A. armena, A. montana, and A. patens, are strikingly beautiful at present, their foliage, as well as their flowers, make them very attractive, and all in this group should be treated with every care, so useful are they at this season. Trillium ovatum and T. grandiflorum are much in evidence. Raffenaldia primuloides and Gentiana verna are happy in the scree. The former is a dwarf Crucifer with golden-yellow flowers, while the latter needs no comment, so charmingly does it hold up its brilliant blue flowers to the midday sun. Shortia uniflora var. grandiflora may be termed an early gem. Its rose-pink flowers are in keeping with the beautiful, leathery foliage, and when grown in large clumps it is superb.

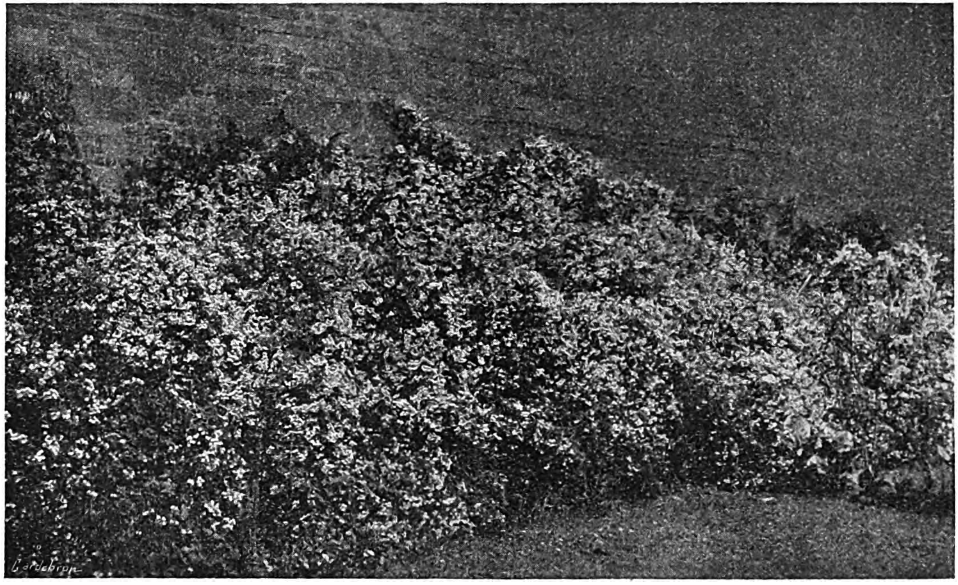

FIG. 167.—LOGAN: CALCEOLARIA VIOLACEA.

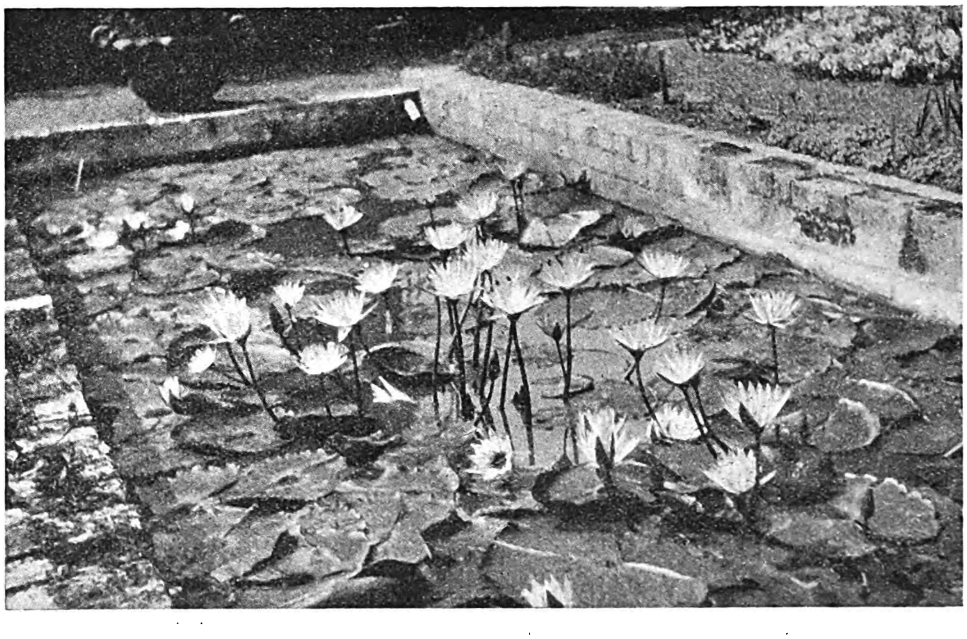

FIG. 168.—LOGAN: NYMPHAEA STELLATA.

The New Zealand Ranunculus Monroi holds up its golden-yellow flowers with great dignity. It is a charming Buttercup and, like the other members of its family, desires a somewhat damp situation. Narcissus cyclamineus, N. Bulbocodium and N. triandrus are giving a wonderful display of dainty flowers and for companions they have the various species of Erythronium.

In a damp, shady border of the Rose garden the remarkable Omphalogramma Farreri has beaten all records. This time it has produced eight wonderful, dark purple flowers, and is also unique in having an absence of foliage at the time of flowering. Its ally, O. vinciflorum, growing near-by, promises well. All the plants of this species are well above ground and looking very robust and healthy. *A. McCutcheon.*

FROST DAMAGE TO HORTICULTURAL CROPS.

In the issue of April 6 there appeared a condensed report of the Ministry of Agriculture's report on the condition of horticultural crops. This showed wide damage had occurred among market garden crops everywhere. There is another set of crops of which I send a report, and it should be of interest to all interested in seeds and gardens. My notes were made in Essex during March and April.

VEGETABLES.

Beans.—All autumn-sown garden Beans killed.

Peas.—We had no autumn-sown edible Peas. Farmers around us have lost all theirs.

Celery.—Not a plant alive.

Onions.—Autumn-sown Onions have all been killed. This I can only state accurately of the Ailsa Craig and Bedfordshire types. I cannot answer for Trebon and other types. Fortunately, bulbs transplanted for seeds have come through safely. These are sown usually in April and transplanted in November. Three-quarters to a full crop of seeds is expected.

Leeks.—All have stood well. The tips of all the leaves went white, but now all are away into fine growth.

Cabbages.—With the exception of York, which are only half-a-crop, all others will give a satisfactory yield. More care than usual has had to be given to cutting open the heads.

Beets.—If half-a-crop is obtained of Globe varieties we shall be lucky. Long Beets are still doubtful, if a quarter-of-a-crop is obtained that will be all.

Turnips.—All are good, but we sow in June and transplant for seeds, selecting roots of all varieties when the size is from large marbles to golf balls, in November.

Carrots.—On the whole, these will be satisfactory. Intermediate is specially promising. Strange to state, Altrincham is disappointing. Carrots are transplanted in November or December when about the size and thickness of one's finger.

Parsley.—This looked very bad for a long time, both transplanted and untransplanted, but is now coming away well and the crop should be about normal.

Parsnips—Hardiest of all the root vegetables. Every root is starting into good growth.

FLOWERS.

Sweet Peas.—Every plant sown outside in autumn has gone. There are very few losses in pots in cold frames, upon which we growers depend almost entirely for seeds. These clumps, knocked out of the pots, are planted out in the fields in March, eighteen inches apart in rows five to six feet apart.

Wallflowers.—These have wintered well, except Fire King. We shall have almost average crops. This is rather singular on stiff land when Wallflowers have all nearly gone on the lighter lands around London.

Candytuft.—This got badly "stung," but the plants were firmly trodden in after the first frost, and this saved fifty to seventy per cent. of them.

Antirrhinums.—All 1928 plants have been killed. In mild winters many beds of these plants stand over and furnish good crops of seeds a second time in the following year.

Pentstemons, Calendulas, Godetias, Clarkias, and all other annuals have been cleaned out like Antirrhinums. This term "cleaned out" is, I believe, correct. The frost forced the young seedlings out of the soil, and hence they died.

Pansies.—About half are dead. The same applies to Hollyhocks.

Primroses are largely killed, while Polyanthuses have not suffered so badly. The gold-laced form of the latter has come through almost unscathed.

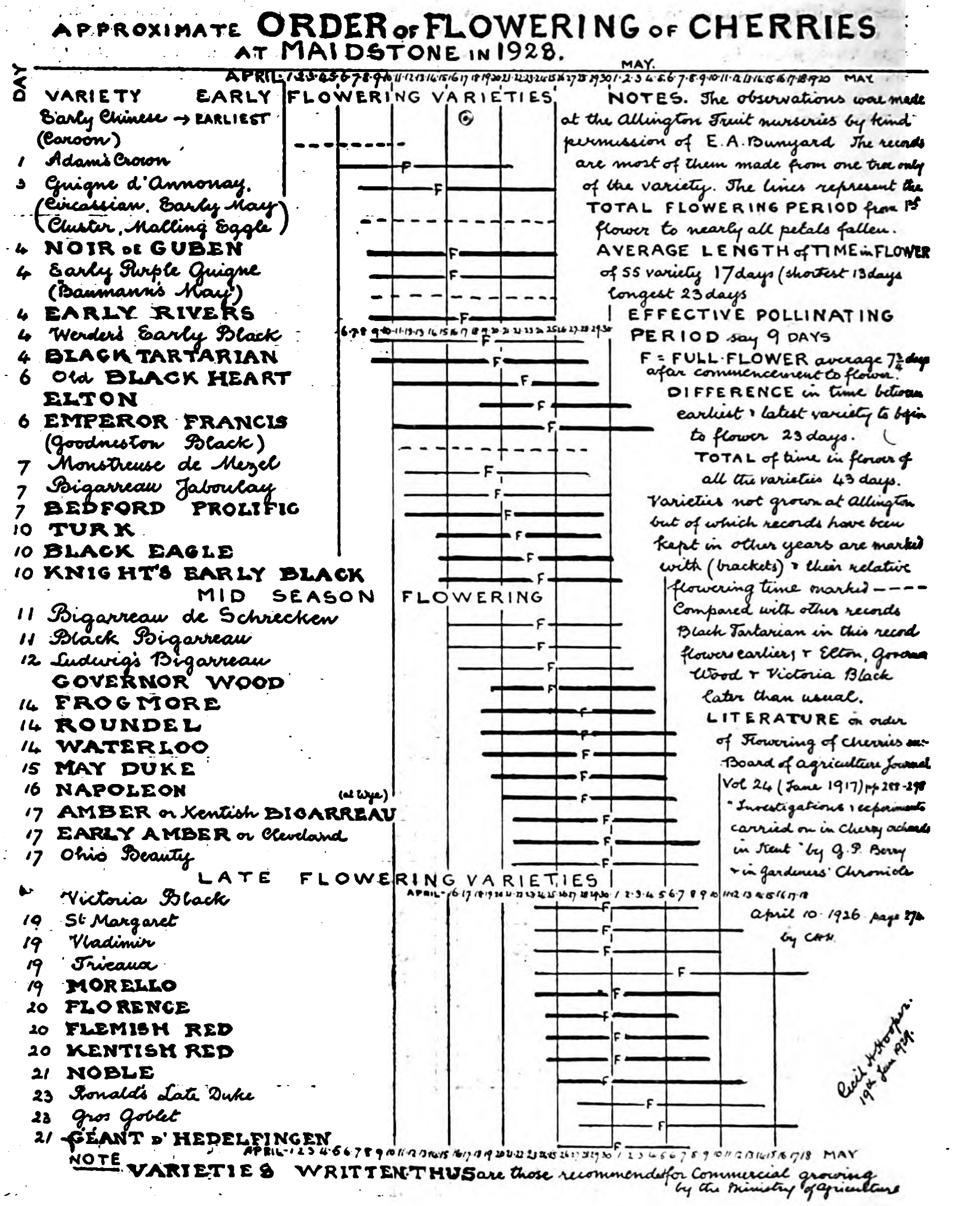
Sweet Williams.—These looked very bad for a long time, but have come away to the extent of seventy-five per cent., but will be late.

Stocks.—East Lothian and Brompton all lost.

Viola Jersey Gem.—Every plant has withstood the winter, also old clumps.

Tulips.—In some two acres of Darwin and Cottage varieties, not a single loss is perceptible.

Lonicera nitida.—Some thousands of small plants were put out a year ago to form a hedge and all have come through the winter safely. *William Cuthbertson, Marks Tey, Essex.*



ORDER OF FLOWERING AND POLLENATION OF FRUIT BLOSSOMS.*

(*Continued from p.* 313).

CHERRIES.

The Agricultural College of Wageningen, Holland, recently published a pamphlet on Cherry pollenation which ends with the following advice to Cherry growers :—

1.—In planting an orchard, plant two or more varieties in such a way that every tree of one variety has a tree of another sort next to it on one side at least.

2.—Keep a good number of hive bees in the Cherry orchard during the blossoming period.

In 1913, V. R. Gardner, of the Oregon Agricultural College Experiment Station, published a bulletin showing that different crosses in Cherries gave different yields ; besides showing that Sweet Cherries were, in general, absolutely self-sterile, he proved that the three chief varieties, Bing, Lambert and Napoleon, were inter-sterile, *i.e.*, would not cross-pollenate each other. Investigations in England at Merton and Wye have shown that most of the Sweet Cherries are absolutely self-sterile, or, if at all self-fruitful, only to the extent of about one per cent., which does not help much towards a crop ; cross pollenation is therefore of very great importance in Sweet Cherries.

The Duke Cherries are slightly self-fruitful and appear to be best pollenated by other Duke varieties and by Morello. Flemish and Kentish Red preserving Cherries are somewhat self-fruitful, but need cross-pollenation. There is a plantation of Flemish Cherries near Ramsgate which is interplanted with Kentish Red ; the crop is generally good and regular, so this seems to be good practice. The Morello Cherry is perfectly self-fruitful ; nothing is gained by cross-pollenation ; this is the only Cherry that can be safely planted alone.

Mr. M. B. Crane, in his valuable investigations at the John Innes Horticultural Institution, has found that among the varieties grown in

---

* A paper read before the Royal Society of Arts, Wednesday, February 13, by Mr. Cecil H. Hooper, F.L.S., of Wye, Kent. ; Mr. H. V. Taylor, O.B.E., Commissioner for Horticulture, Ministry of Agriculture, presided.

England there are groups of Cherries that are inter-sterile, and that one should avoid planting them together alone. These are:—1, Early Rivers, Knight's Early Black, Bedfordshire Prolific, Black Tartarian and Black Eagle; 2, Frogmore, Guigne de Winkler, Waterloo and Bigarreau de Schrecken; and 3, Napoleon and Emperor Francis.

Early Rivers, being the most profitable Cherry, has sometimes been planted alone in large quantities, when it is found that the inside trees bear very small crops. Some Kentish growers (Sir Walter Berry at Selling, Mr. W. J. Thomas at Rodmersham, and Mr. H. Stevens at Wye, have each found that a variety known as "Baumann's May" is a good cross-polleniser for Early Rivers; it flowers at the same time and is ripe soon after Early Rivers, which it resembles.

In choosing varieties of Cherry to plant together one needs to avoid planting early-flowering with late-flowering varieties alone; a mid-season flowering sort might pollenate both the early- and late-flowering varieties, bridging the difference in time of flowering.

I have made a table, collected from the results of experiments and orchard observation from several sources, which I hope may act as a guide in choosing varieties of Cherries suitable to plant together; and another showing the approximate order of flowering of Cherries.

The most productive Cherry orchards I know are planted with several varieties, and bees are kept in the orchards. If one cannot manage to have one hive per acre, have a hive to five acres. It will be found to be far better than having none.

An excellent bulletin on "Pollination and Growing of the Cherry," by C. E. Schuster, was published in 1925 by the Oregon Agricultural College Experiment Station, which gives useful information on planting and re-grafting Cherries.

(*To be concluded*).

NOTES

0 = matured no fruit with this pollen

1 = a very good cross pollenizer

2 = a second best variety for cross-pollination

3 = a less good cross pollenizer

4 = not recommended as a pollenizer

1/100 = matures about one fruit from 100 flowers.

GARDEN MANURES FOR MAY.

In modern soil chemistry it is recognised that perfect plant nutrition depends on the presence, in an available form, of all the elements necessary to plant life, and the object of using artificial manures in the production of crops is to maintain a suitable balance of these elements, by adding fertilisers containing them in varied forms and proportions, according to the known deficiency of the soil under treatment, or the specific need of the crop in question. Just as soils vary largely in their constitution, so plants vary considerably in their requirements; some need more nitrogen, some need more potash, and some need more phosphorous than others, and almost every crop, or group of crops, may be stated to have its dominant manurial requirement, which is illustrated by the generalised statement—use nitrogen for producing leaves, phosphorus for roots, and potash for fruits.

But under all conditions, and for all crops, nitrogen plays an important part in plant development, and probably no manures give such quick results as artificial nitrogenous fertilisers, most of which are suitable for application during the growing season. While there is a considerable number of so-called nitrogenous manures giving nitrogen as their chief element, the two most important are nitrate of soda and sulphate of ammonia, the use of which tends to increase under modern intensive methods of cultivation, and both of which have powerful fertilising properties that can best be made use of during the season of active growth, and should not be applied when growth is maturing.

Up to comparatively recent times, nitrate of soda was the best-known and most widely used, but it had no definitely fixed standard of purity as, in its natural state, it is contaminated with large quantities of sulphates, common salt and ordinary earth and, although some of these were extracted before exportation, inferior grades were not uncommon; moreover, as there was no great competition with other fertilisers of a similar nature, there was no incentive to standardise. The increasing use of sulphate of ammonia in this country, however, has resulted in nitrate of soda of higher purity, and one may rely on the average sample of to-day containing not less than 15½ per cent. of nitrogen. Sulphate of ammonia, however, contains considerably over 20 per cent. of nitrogen, and at current prices its cost, based on the unit value, is very much lower than that of nitrate of soda.

In spite of the apparent cheapness of sulphate of ammonia, there are some growers who prefer to use nitrate of soda, and there is no doubt that on certain soils, and applied to certain crops, each have special advantages. A good deal depends on the character of the season, and in a very dry season probably special advantages acrue from the use of nitrate of soda, but it cannot be too forcibly emphasised that both manures can only produce the whole of their useful effects when the soil to which they are applied already contains a sufficient proportion, and in a properly assimilable condition, of the other elements required by the plant. Nitrate of soda is certainly quicker in action than sulphate of ammonia, and for this reason may be preferred for special purposes, but for general purposes this may be a disadvantage, in that the nitrate only has to be converted into a nitrite to become assimilable by the plant, and if for any reason the plant cannot absorb it immediately, loss ensues.

The conversion of the nitrogen in sulphate of ammonia into nitrates takes place in several stages, thus needing more time to effect it, but even then its action is relatively quick, and the plant derives benefit in a few weeks after application. There is a prevailing idea that sulphate of ammonia cannot be applied to growing crops, but this is quite erroneous, as in most cases where nitrate of soda could be used sulphate of ammonia gives at least equal, if less quick, results. It is, of course, necessary to avoid dusting the foliage of any plant with it, but in most garden crops it is quite easy to apply it between the rows in the early stages of growth without touching the foliage.

Some authorities advocate an application before the sowing or planting of the crop, and assert that better results accrue when this is done than when the manure is applied as a top-dressing during the early stages of growth. There does not appear to be sufficient evidence to substantiate this assertion under all conditions, however, and until such evidence is conclusive, I should prefer to advise its application, in so far as garden crops are concerned, during the early stages of growth. It is admittedly a great advantage to be able to apply it when preparing the ground for the field cultivation of Potatos, for example, but in the relatively restricted areas under garden cultivation, where in any case hand distribution is practised, its application between the rows after growth has commenced creates no difficulties.

There is an old prejudice against the use of these powerful fertilisers, because they were regarded not as plant foods, but merely as stimulants, which, in spite of modern education, has not entirely disappeared, but there is no gainsaying the fact that they form a ready means of supplying in a concentrated and quick-acting form, an element greatly needed by the plant for its full development, and, when used with discretion, afford valuable feeding properties. *W. Auton.*

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Royal Horticultural Society's Accounts for 1928.—With regard to the article in your issue of April 13, my reference to the Fowler-Reader-Harper complex must not be interpreted as the Wilks tradition. Gurney Fowler is responsible for the present form of the Royal Horticultural Society's accounts. His teaching was religiously adhered to by Frank Reader. Now Gurney Fowler was a notable accountant and Frank Reader worked as long and as hard as three ordinary men. The system had the support of the Society's auditor, who has always pointed out that a change of method would at once make it impossible to compare a new statement with previous years. (In this connection, however, it is pertinent to point out that King Edward's Hospital Fund has required the hospitals to revise their systems). Personally, I have always advocated a policy of giving the fullest information to Fellows at the earliest date. Now a word on the subject of Wisley. Certain things are done very well indeed, viz. :—(a) The plant trials and permanent collections are of the utmost value in enabling Fellows and their friends to make selections of varieties; (b) Rhododendrons and other shrubs, also Heaths, are well cultivated, and the range is extensive; (c) the alpine house is a model and the cultivation of alpines is not excelled elsewhere in this country; and (d) the experimental fruit trials are admirably conducted. On the other hand, the School of Horticulture is an amorphous concern, and, if it is to be continued, should be reorganised on collegiate lines with hostel and sports grounds; at present there is no sodality. I should like to see the school develop and ultimately become a School of the University of London. The distribution of plants to Fellows is a real abuse. These plants are not "surplus," but are specially grown for the purpose; their cultivation and distribution wastes the time of the staff. I think the general distribution should be confined to a seed-list; and the Director would exercise his discretion in the supply of special plants on the lines of Kew and Edinburgh. To sum up: A very high standard is obtained in many departments at Wisley, and should prevail in all. This will involve spending more and not less money on the institution. Fellows have a tendency to abuse their privileges; an extreme case is the £2 2s. subscriber who passes on his two transferable tickets at, say, 17s. 6d. each, and thus for 7s. obtains admission to shows, plants from the distribution, and the *Journal*, to say nothing of minor privileges. How many of your readers can describe the work of the Royal Horticultural Society? The note to the By-Laws states: "It is an educational Society, for both the practice and the science of horticulture. It holds frequent meetings and lectures for the purpose of gathering together specimens of plants, fruits, flowers and vegetables, etc., demonstrating the continued advance being made in horticulture by the application of science and scientific methods; maintains a school, holds examinations, and conducts scientific research at its gardens, trial grounds and laboratories." Again, the schedule of the Chelsea Show begins in the same lofty strain: "The purpose of the President and Council in promoting these shows is partly educational and partly scientific." These are high ideals, and sincere administration will uphold them. *William Lawrence.*

The Chelsea Nurseries.—Your correspondent *W. P. W.* (p. 268), brings back very pleasant memories of the Chelsea nurseries just over forty years ago, when I used to visit Messrs. J. Veitch and Sons on business. Regarding George Schneider of the Fern department, I once heard him described as the very best Frenchman that ever came to England; he was always ready to give a helping hand to any young gardener, either French or English; he was at the time finishing *The Book of Choice Ferns*, and he related his experiences in 1870 during the Franco-Prussian war. My eldest son, a boy at school, has never forgotten it, and I well remember Schneider saying that one of the greatest comforts during the campaign was a good pair of English boots, as he was in England when the war started, and went back to France to fight for his country. I spent a very enjoyable day with him, not long before his death, at Barnes, where he lived after retirement. I also knew Mr. Minns and Mr. Tivey, and the wonderful fruit nursery at Southfields — long since built over. I have fruit trees now under my charge that came from Southfields forty years ago, in fine condition. *F. E.*

Cauliflowers.—An outstanding variety, grown rather as a second-early, is Drancourt (or Driancourt). This is largely grown in the Vale of Evesham, and being conversant with most of the sorts grown, I can state that for purity, size and outstanding quality it easily beats the others in its season. Unfortunately, it is not found under its proper name in many seedsmen's catalogues, and therefore is rather difficult to get, except locally. *G. H. E., Taplow.*

Partial Soil Sterilisation.—With further reference to Soil Sterilisation, I have received from growers all over the country letters of appreciation on the Reaseheath method of sterilisation, and, as many readers are no doubt aware, Messrs. Edmunds, of Cambridge, have adopted this method for raising plants. I have, however, received one letter from Mr. S. D. Overall, gardener to Gordon Stewart, Esq., of Ripley, Surrey, which, I think, is worth while publishing in order to convince incredulous readers:—"I thank you for particulars of Reaseheath Steriliser. I have given it a fair test and think it a better method than steam sterilisation. I have given both a good trial, and so far as I can discover the baked soil gives the best results. I have a lot of plants growing well in it, beside plants growing in steam-sterilised soil, and the plants are quite as vigorous and healthy, if not more so, and I have plants in unsterilised soil, which look quite sick beside the others. I find the Reaseheath plant more economical to run; also my loam is rather heavy, and with steam, I cannot get it into such a texture for use as the baked. The steamed soil takes days to dry, and then is not like the baked soil which I am using after two days from sterilising. I have made a steriliser large enough to do about one load at a time, and must state I am very pleased with it, thanks to you. I shall recommend your plant to anyone who is interested." I publish this letter with the permission of Mr. Overall, a gentleman I have not had the pleasure of meeting. *W. E. Shewell-Cooper, Reaseheath, Cheshire.*

SOCIETIES.

MIDLAND DAFFODIL.

APRIL 24 AND 25.—Owing to the lateness of the season, this Society's show, originally fixed for April 17 and 18, had to be postponed for a week. The show, which was held at the Edgbaston Botanical Gardens, was very extensive, thoroughly representative of the Daffodil in all its varied forms, and included a goodly number of new varieties of great merit. Mr. GUY L. WILSON and the DONARD NURSERY Co. were the most successful prize-winners, the first-named breaking the record by winning six Cups and Trophies. Unfortunately, the weather on both days was very cold, and the attendance was smaller than usual.

Groups of miscellaneous flowers and floral designs were also included and gave variety and additional interest to the show. The Floral Committee gave thirteen Awards of Merit to Daffodils, which are briefly described below.

At the Annual General Meeting, held on the first day of the show, the Society's financial position was pronounced to be very satisfactory; all the officers were re-elected, and additions made to the General Committee and Floral Committee. During the discussion, many useful suggestions were made for next year's schedule, for which a Sub-committee was appointed.

AWARDS OF MERIT.

Narcissus Kantara.—A bold, substantial flower, with a delightfully broad, white perianth, and large, white, crimped trumpet.

N. Peter Lower.—This belongs to the Tazetta section, has a lovely white perianth and a rich orange centre.

N. May Molony.—See *Gard. Chron.*, April 20, 1929, p. 300. The above three varieties were shown by Mr. GUY L. WILSON, Broughshane, Antrim.

N. Silver Plane.—A refined, pure white Leedsii form with a broad, overlapping, flat perianth and a flat, canary-yellow cup.

N. Festire.—A bicolor Incomparabilis with a white, pointed perianth suffused with yellow, and a shapely, crinkled crown, touched with orange-scarlet.

N. Market Glory.—A handsome, canary-yellow Incomparabilis with a rich orange-yellow, frilled crown. These three varieties were shown by THE DONARD NURSERY Co., Newcastle, Co. Down.

N. Mrs. Watts.—An Incomparabilis variety with a thick, creamy-white, overlapping perianth, and intense orange, crinkled crown.

N. Jorrocks.—This is a fine, strong-stemmed Incomparabilis variety with a well-formed, canary-yellow perianth, and large, deep orange, frilled cup. These two varieties were shown by Mr. W. A. WATTS, St. Asaph.

N. Radium.—A choice Barrii variety in which the white ground perianth is clearly suffused with buff. The cup is rich orange.

N. Sunstar.—Another bright Barrii variety with a stout, circular perianth and deep orange cup.

N. Sumaria.—Flowers large and well-formed, with a broad, flat, overlapping, satiny-white perianth and cup.

N. Folly.—A beautiful bicolor Incomparabilis with a broad, pure white perianth and rich orange-red crown.

N. Crimea.—This is a charming bicolor Barrii with a flat perianth and rich orange, crimped cup. The last-named five varieties were shown by Mr. J. LIONEL RICHARDSON, Waterford.

OPEN CLASSES.

The first class required thirty-six varieties representing, so far as possible, the different divisions, and three stems of each variety had to be shown. Although the DONARD NURSERY Co. were the only exhibitors, they were deservedly awarded first prize, as they had a beautifully clean lot of well set-up flowers in which the following varieties were most conspicuous, viz., Helmet, Croesus, Silver Plane, Brimstone, Sunstar, Mitylene, Warspite, Hexagon, Market Glory, Festive, Blizzard, Peter Pan, White Lady, Rosary, Carmel, Donax, Buttercup, and many unnamed seedlings.

The best twelve varieties, three stems each, of yellow, white and bicolor Trumpets, came from Mr. Guy L. Wilson, who showed handsome flowers of Honey Boy, Beersheba, His Excellency, Lord Antrim, Kantara, Countess of Antrim, Sorley Boy, and unnamed seedlings; second, The Donard Nursery Co., with shapely flowers of Brimstone, Lady Primrose, Kantara, Beersheba, Herod and White Conqueror.

The winning sets of half-a-dozen yellow Trumpet Daffodils also came from the above-named exhibitors, who were placed in the same order. Mr. Wilson's collection included exquisite blooms of Honey Boy and His Excellency. The best flowers in the second prize lot were of Brimstone, Cleopatra and Golden King; third, Mr. W. A. Watts.

In the class for six white Trumpet varieties, Mr. Guy L. Wilson was again successful, with excellent specimens of Kantara, Beersheba, Eskimo and Kenbane. Mr. W. B. Cranfield, of Enfield, who was placed second, had smaller but beautifully fresh and clean blooms which included Beersheba and Clair de Lune; third, The Donard Nursery Co.

Mr. G. L. Wilson also took the lead in the class for half-a-dozen bicolor-Trumpet varieties. His best blooms were Honour, Jack Spratt and Rosary; second, The Donard Nursery Co., who had Carmel, Jersey Cream and Vestal Virgin in excellent condition: third, Mr. W. B. Cranfield. The Donard Nursery Co. led in the class for six Incomparabilis varieties, Dingo, Market Glory and Hopeful being the pick of a really good lot; second, Mr. W. A. Watts, whose flowers of Jorrocks, Joker and Peggy Briscoe were surprisingly good; Mr. W. B. Cranfield's third prize collection included a beautiful vase of Croesus.

In the class for six white Incomparabilis varieties, The Donard Nursery Co. were again placed first. They showed charming specimens of Great Warley, Folly and Lady Mary Boscawen; second, the Rev. T. Buncombe, Black Torrington, Devon., whose vase of Gunthorpe Belle was very beautiful. The first and second prize sets of six yellow Barrii varieties also came from The Donard Nursery Co., and the Rev. T. Buncombe, who were placed in the order named. In a similar class for six white Barrii varieties, Mr. G. L. Wilson was to the fore with well set up flowers of Firetail, Lilian McLean, Dragoon, Galata and Crucible; second, The Donard Nursery Co., who had splendid examples of Sunstar, Lady Moore and Harpagon; third, the Rev. T. Buncombe.

The winning exhibitor in the class for six large-cupped Leedsii varieties was Mr. G. L. Wilson, whose long, strong-stemmed, beautifully-formed blooms of Suda, Okapi and Riva were of great merit; second, The Donard Nursery Co., whose best flowers were Mitylene, Suda, Hexagon and Blizzard; third, Mr. W. B. Cranfield. Mr. G. L. Wilson also had the best six small-cupped Leedsii varieties, and his Silver Plane and Hera were uncommonly good; second, The Donard Nursery Co.

The last-named exhibitors showed the best stand of six Triandrus hybrids, which included lovely examples of Silver Cloud, Venetia and Harvest Moon; second, Mr. W. B. Cranfield. The Donard Nursery Co. excelled in the class for six Poeticus varieties, with Antarctic and Thetis in excellent condition, second, the Rev. T. Buncombe.

Single Bloom Classes.

Yellow Trumpet Variety.—First, Mr. G. P. Cope, Albrighton, with an unusually large, richly coloured flower of Alchemist; second, Mr. W. B. Cranfield, with Harpist.

White Trumpet.—First, Mr. J. S. Arkwright, with a grand bloom of Beersheba; second, The Donard Nursery Co., with Askelon.

Bicolor Trumpet.—First, Mr. W. B. Cranfield, with Moira O'Neill; second, Mr. J. S. Arkwright, with an unnamed seedling.

Yellow Incomparabilis.—First, Mr. W. B. Cranfield, with an intensely coloured bloom of Farthingdale; second, The Donard Nursery Co., with Croesus.

Bicolor Incomparabilis.—First, The Donard Nursery Co., with a shapely flower of Festive; second, Mr. W. A. Watts, with Curlew.

Yellow Barrii.—First, Dr. D. R. Acheson, with Seraglio; second, Mr. W. A. Watts, with Minafon.

White Barrii.—First, The Donard Nursery Co., with Firetail; second, Mr. W. A. Watts, with Muriel Bibby.

Large-crowned Leedsii.—First, Mr. W. B. Cranfield, with Mitylene: Mr. J. S. Arkwright and The Donard Nursery Co. were placed equal second with Taffy and Tenedos, respectively.

Small-crowned Leedsii.—First, The Donard Nursery Co., with a beautiful flower of Silver Plane; second, Mr. W. A. Watts, with Honey.

Triandrus Hybrid.—First, Mr. W. B. Cranfield, with Venetia; second, The Donard Nursery Co., also with Venetia.

Cyclamineus Hybrid. First, The Donard Nursery Co., with Orange Glory; second, Mr. H. A. Marriner, with an unnamed variety.

Jonquilla Hybrid.—First, The Donard Nursery Co., with Solleret; second, Mr. J. S. Arkwright, with seedling No. 19.

Tazetta or Tazetta Hybrid.—First, The Donard Nursery Co., with Glorious; second, Dr. D. R. Acheson, with Medusa.

True Poeticus.—First, Mr. W. B. Cranfield, with Opera; second, The Donard Nursery Co., with Ace of Diamonds.

Doubles.—First, Mr. W. A. Watts, with Lloyd; second, Dr. D. R. Acheson, with Mary Copeland.

Seedlings and New Varieties.

The much coveted Bourne Challenge Cup, offered for twelve varieties, one stem of each, raised by the exhibitor, was awarded to last year's winner—Mr. Guy L. Wilson, whose flowers of May Molony, Buff Barrii and unnamed seedlings, were exquisitely beautiful. Mr. J. S. Arkwright, Presteign, was second, with unnamed seedlings.

The winning set of six varieties raised by the exhibitor came from The Donard Nursery Co., who had wonderfully fine examples all under

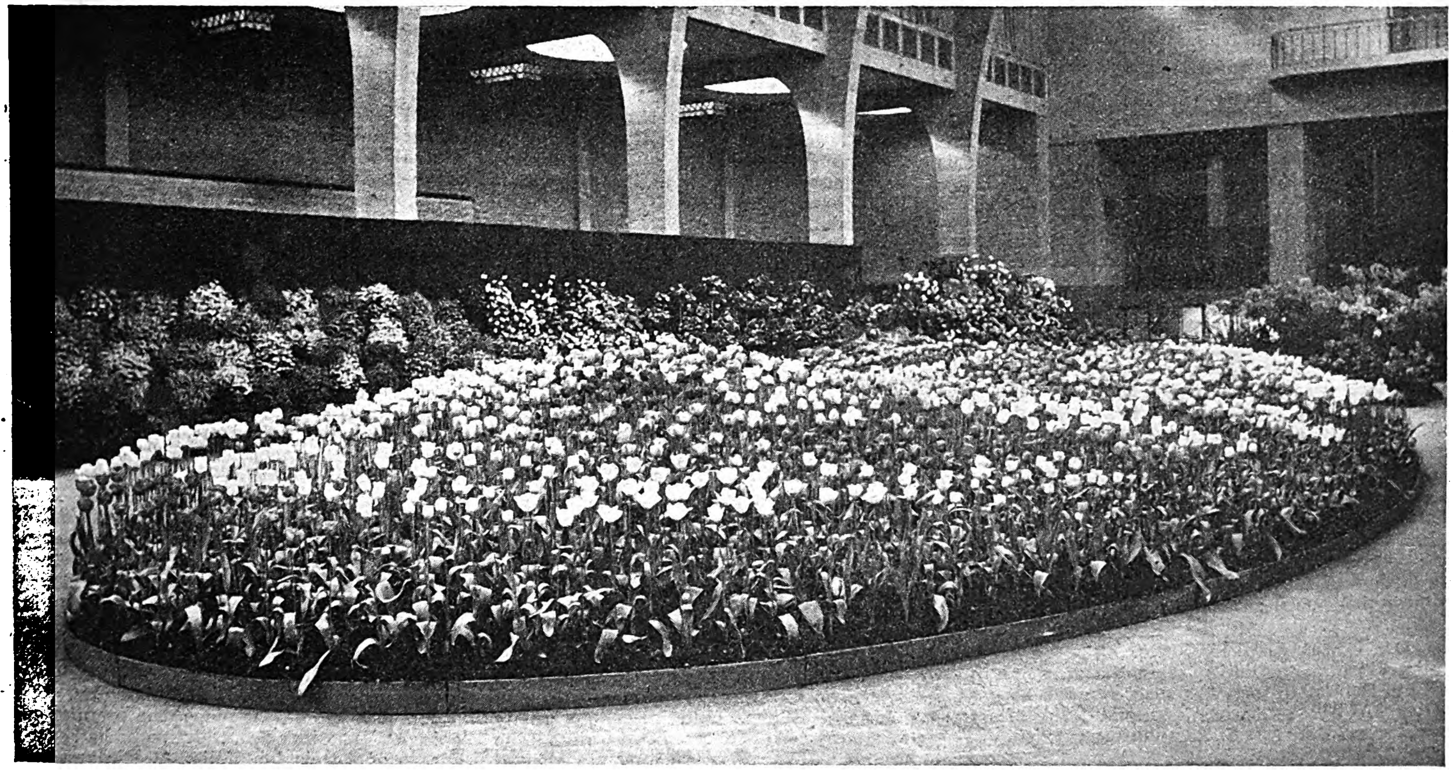

FIG. 169.—MESSRS. SUTTON AND SONS' GOLD MEDAL EXHIBIT OF TULIPS AT WESTMINSTER (see p. 316).

numbers; second, the Rev. T. Buncombe; third, Mr. J. E. Exley, Leeds. There were only two entries in the smaller class for three varieties raised by the exhibitor. Miss Pope, Northfield, was first, and Mr. H. A. Marriner, Billingshurst, was second.

The Cartwright Challenge Cup was offered for twelve varieties in commerce, one stem of each. First, The Donard Nursery Co., who showed handsome blooms of Seashell, Silver Plane, Sunstar, Kenbane, Firetail, Festive, Brimstone and Mitylene. The second award went to Mr. W. B. Cranfield, who had choice specimens of Seashell, Solleret, White Chevron, Helmet and Lady Moore. In a smaller class for six varieties in commerce, Dr. D. R. Acheson won first prize, and the Rev. T. Buncombe, second prize. The only exhibitor in the class for three varieties in commerce, one stem of each, was Mr. J. E. Exley, who showed a very creditable set.

The Walter Ware Challenge Cup, offered for six obvious Triandrus seedlings, one stem of each, was won by Mr. W. B. Cranfield, with pleasing flowers of Venetia, Waterfall, Maid Monica, Harvest Moon, Silver Cloud and No. 442; second The Donard Nursery Co.; third, Mr. W. A. Watts.

The White Daffodil Trophy always attracts a good entry. Mr. Guy L. Wilson was first with a splendid collection which included Kantara, Beersheba and unnamed seedlings; second, The Donard Nursery Co., whose best flowers were Askelon and Beersheba.

The Leamington Challenge Cup, offered for six varieties with red coronas, one stem of each, was won by Mr. Guy L. Wilson, who had Peter Lower, Torrid, Copper Bowl, Kilter and unnamed seedlings in fresh condition and first-rate quality; second, Mr. J. Lionel Richardson, Waterford, with high quality blooms of Rodosto, Radium, Red Sun, Balaclava, Folly and Stamboul; third, Mr. W. A. Watts.

The Arkwright Challenge Cup, offered for six bicolor Trumpet varieties, one stem of each, was also won by Mr. Guy L. Wilson, with excellent flowers of Jack Spratt, 18-26, C. B., Rosemorran Giant, 16-101 and 18-117; second, Mr. J. S. Arkwright; third, The Donard Nursery Co.

The Williams Challenge Cup, offered for six varieties of yellow shades without red colouring in the cup, was won by Mr. Guy L. Wilson, who had magnificent flowers of Hopeful and Flava; second, The Donard Nursery Co., whose flowers of Brimstone and Cleopatra were of outstanding merit; third, Mr. J. S. Arkwright.

The Dr. Lower Challenge Cup, offered for six yellow Trumpet varieties, one stem of each, raised by the exhibitor, was also secured by Mr. Guy L. Wilson, with a splendid lot of flowers; second, Mr. J. S. Arkwright; third, the Rev. T. Buncombe.

Amateur Classes.

There were six splendid entries in the class for twenty-four varieties of Daffodils, three stems of each, and the quality of the blooms throughout was of a high standard of excellence. Mr. G. H. Furness, Burnham, was placed first with a clean, well set-up collection, including the varieties Great Warley, Macebearer, Croesus, Buttercup, Ivorine and Lord Roberts; second, Mr. W. Fitzherbert, who had handsome blooms of Homer, Dawson City, Lady Moore, White Sentinel, Selina and Malone; third, Miss Hinchliffe, Instow. The best half-dozen Trumpet varieties came from the last-named exhibitor, Mr. G. H. Furness, Burnham, being second. Miss Hinchliffe also had the leading set of three varieties, one stem of each, raised by the exhibitor; Mr. A. H. Bassano, Old Hill, Staffordshire, was second.

In the class for six Incomparabilis, Mr. G. H. Furness scored, showing very fine blooms of Croesus and Leontes; second, Mrs. E. V. Butler, Tewkesbury. The last-named was successful in classes for (1) six Barrii varieties and (2), six Leedsii varieties. Mr. G. H. Furness was placed second in each of the above two classes, and first for three varieties of Tazetta and Tazetta hybrids. Miss Hinchliffe excelled in the class for three varieties of Poet's Daffodils, and Mr. G. H. Furness won the Cartwright and Goodwin Silver Vase offered for six varieties (any divisions). Dr. D. R. Acheson was second in each of the two foregoing classes.

Mr. W. Fitzherbert won first prizes for (1) twelve varieties of Daffodils; (2) six Trumpet varieties; (3) six Incomparabilis varieties; (4) six Barrii varieties; (5) six Leedsii varieties; (6) six Poeticus varieties and (7), a bowl of Daffodils. In the last-named class, the Rev. T. Buncombe was second, and Miss Pope, third. Miss Pope was awarded first prize for a prettily arranged table (about three feet square) of hardy spring flowers.

Medal Awards.

The Birmingham Botanical and Horticultural Society's Medals were awarded as follow:—Classes 1 to 29: Silver Medal to The Donard Nursery Co., with 170 points; Bronze Medal to Mr. Guy L. Wilson, with 74 points. Classes 15 to 29 and 30 to 41: Silver Medal to The Donard Nursery Co., with 93 points; Bronze Medal to Mr. Guy L. Wilson, with 64 points; Classes 15 to 29 and 43 to 57: Silver Medal to Mr. W. Fitzherbert, with 64 points; Bronze Medal to Mr. G. H. Furness, with 49 points.

Honorary Exhibits.

Messrs. Barr and Sons were represented by an extensive display of beautifully arranged Daffodils. Of the host of varieties included in this very fine collection, the under-mentioned were conspicuous:—Susette, Red Gauntlet, Kingdom, Scarlet Gem, Grecian Beauty, White Nile, Beersheba, Fantin Latour, Eskimo, John Evelyn, Moira O'Neill, Dorcas and White Emperor (Gold Medal).

Mr. Guy L. Wilson had a choice collection of Daffodils, including such varieties as Suvla, Beersheba, Kantara, Ettrick, Carmel, Peter Lower, May Molony, Crucible, Market Glory, Dragoon and many unnamed seedlings (Gold Medal). Mr. W. A. Watts had one of the biggest and best groups of Daffodils he has ever staged at Birmingham. The flowers, set principally in low bowls and vases and artistically arranged, were fresh and clean, and included many varieties suitable for garden and market purposes. A few varieties of outstanding merit were Joker (intense orange crown), Hernia, Mrs. Watts, Lemon Ice, Jorrocks (very fine), Owen, Girdle, Lloyd. Minafon, Jason, Estelle and Jingle (Gold Medal).

Messrs. R. H. Bath, Ltd., staged a handsome group of Daffodils which included most of the best garden and market varieties (Gold Medal). Messrs. Allwood Brothers made a feature of Carnations and Pinks, bold masses of many varieties being seen to excellent advantage (Gold Medal). Messrs. Baker were represented by a selection of floral designs, hardy shrubs, and rock and border plants in variety (Gold Medal). Mrs. Lower, Malvern Wells, contributed about thirty varieties of seedling Daffodils for which a Silver-gilt Medal was awarded. A similar award was also made to Mr. W. A. Milner, Sheffield, for an interesting collection of seedling Daffodils. Messrs. Cartwright and Goodwin received a Silver Medal for Daffodils. Mr. J. L. Richardson contributed a small, choice lot of seedling Daffodils, and Miss K. Morris, Kidderminster, arranged a miniature garden.

PROFESSIONAL GARDENERS'.

The monthly meeting of this Association was held at the Guildford Hotel, Leeds, early in April, Mr. J. T. McCormack presiding.

Mr. Garvin Little, Gardener at Studley Royal, Ripon, lectured to a large gathering on "Vegetables for Exhibition," dealing in turn with Onions, Leeks, Celery, Peas, Cauliflowers, Carrots, Potatos and Parsnips, as eight subjects which, if grown well, will hold their own at any show. A very good discussion followed. After a formal vote of thanks was accorded Mr. Little, who had to leave, the members spent another interesting hour discussing the wording of show schedules and the principles of judging.

THE CORNWALL SPRING SHOW.

The Cornwall Spring Show, which was held at the City Hall, Truro, on April 23 and 24, provided an extraordinary display of choice and out-of-season flowers. Many of the flowering shrubs exhibited can only be grown out-of-doors in Cornwall. Rhododendrons were not exhibited in such a large quantity as in previous years, although the collection of species and hybrids displayed by Mr. J. C. Williams, of Caerhays, attracted much attention, well-grown specimens included in his exhibit being R. Cunningham's Yellow, R. Augustinii, R. Loderii and R. arboreum. Successful exhibitors in the competitive Rhododendron classes were Major G. H. Johnstone, Trewithen; Mr. Barclay Fox, Penjerrick; Mrs. Hext, Mr. Magor, Lamellyn; and Mr. P. D. Williams, Lanarth, the outstanding blooms being of R. Cornish Cross, R. Aucklandii and R. campylocarpum.

Another centre of attraction was the wonderful display of flowering shrubs in the class for twelve vases. As usual, the Rev. A. T. Boscawen, Ludgvan, excelled. A vase of Podalyria was very striking, while other very attractive subjects in this exhibit were Sophora tetraptera, Epacris mineata, E. onosmaeflora, Staphylea holocarpa and Erica melanthera. The second prize went to the Hon. Mrs. Colborne Vivian, St. Martin, who showed fine sprays of Clematis indivisa, Clianthus puniceus and Acacia longifolia.

Tulips were not so much in evidence as usual, the best exhibit being staged by Miss Wingfield, Gulval, whose finest blooms were of Moonlight, Zwanenberg, and General French. The competition in the Anemone class was very keen, Mrs. Henderson Bull, Falmouth, staging some extraordinarily fine specimens, her new pink strain being much admired; this received a special award.

Assorted spring flowers were well represented and rock gardens also occupied a prominent place. In the former section, Miss Lavender Williams, St. Keverne, took first place, and her exhibit contained some well-grown sprays of Omphalodes cornifolia, Vinca herbacea, Tulipa Clusiana, and Lysichytum camtschatcense; Mrs. Paynter, Boskenna, was second, and she included Celsia cretica, Primula helodoxa and Myosotidium nobile in her exhibit. Another subject which attracted attention was a fruiting branch of Araucaria Bidwillii, put up by Mr. Barclay Fox, of Penjerrick.

Although somewhat late in the season, a fair number of Narcissi were staged, and in the class for six vases, Mr. F. G. Lawson, Truro, was first, and included excellent examples of Seville, Cheerfulness, Hera and Firetail.

As one would expect at this show, Acacias occupied a prominent place, the premier award going to Viscount Falmouth, who had excellent sprays of Acacia longifolia, A. Riceana and A. melanoxylon. In the Erica class, Mrs. Powys Rogers, of Tregye, was successful, her exhibit containing a grand spray of Erica arborea var. Mr. Robert.

The trade was well represented and in the Narcissus section, Messrs. J. C. Martin and Messrs. W. G. Lawson had very fine exhibits. The most noticeable blooms in the former's group were Great Leap, Silver Penny and Water Lily, and this exhibitor had some well-packed commercial boxes. In the latter's there were well-grown flowers of Croesus, Seville, Owen, Sprite and St. Bernard. Mixed displays were staged by Messrs. Treseder and Co. who showed choice shrubs and alpines, and the Devon Rosery, who made special features of Clematises, Roses, Acacias and Hippeastrums. Messrs. R. Veitch and Son, as usual, had a most interesting exhibit containing many choice and uncommon plants. Other exhibitors were Messrs. Ruse, Messrs. Davis, Messrs. Cocking and Messrs. Allwood Brothers, who had a very fine display of Carnations. A fine non-competitive exhibit was also staged by Mr. Henry Hodge, of St. Austell.

The Gardeners' Chronicle Silver-gilt Medal was won by Mr. James Allen, Truro, and the Silver Medal by Mr. R. Nancarrow, also of Truro.

RHODODENDRON ASSOCIATION.

April 30 and May 1.—The fourth show of Rhododendrons, which was held in the New Horticultural Hall, Westminster, on these dates, well illustrated the great diversity and garden possibilities of these valuable and interesting shrubs. In spite of the unfavourable weather, which prevented several members of the Association from setting up their usual collections, there was a very good show. The central part of the hall was filled with the groups of the various classes, and these made an exceedingly attractive display. Section B of the R.H.S. Floral Committee met in the morning of the first day, under the chairmanship of Mr. Charles T. Musgrave, and recommended the following awards to Rhododendron novelties.

Awards of Merit.

Rhododendron Keiskii.—This comparatively dwarf, evergreen species was introduced from Japan in 1908. The plant shown was compact and well-flowered. The loose trusses were composed of from two to five pale yellow flowers about an inch-and-a-half in diameter. It belongs to the 'Triflorum' series. Shown by Mr. Harry White.

Rhododendron semanteum.—This pretty little species was discovered by Forrest on the Muli Mountains, south-west Szechuan, at a considerable altitude, in 1921. It belongs to the 'Lapponicum' series. Several very dwarf and somewhat spreading plants were shown, and these were in full bloom when less than three inches in height. The flowers, which expand widely, are relatively large and of deep rosy-mauve colour. Also shown by Mr. Harry White.

Rhododendron tephropeplum.—This was one of the most delightful of the small-flowered Rhododendrons in the show. The species was discovered by Farrer in Upper Burma at over 10,000 feet altitude, in 1920, and it is placed in the 'Campylogynum' series. It is an erect little bush, and each shoot seems to be terminated with rounded heads of bell-shaped flowers, which are shell-pink outside and blush shaded within. The leaves are lanceolate-acuminate. Shown by Lady Aberconway (gr. Mr. F. C. Puddle), Bodnant, North Wales.

Groups of Rhododendrons.

The competition in the class for a large group of Rhododendron plants shown by a trade grower was not quite so keen as on former occasions. Messrs. R. Gill and Son were awarded the first prize for an imposing display. Probably from lack of time, name cards were sparsely used. The chief sorts so well shown were fragrantissima, delicata, Dalhousiae, neriiflorum, sino-grande, decorum, bullatum and Thomsonii. In their neat second prize display, Messrs. R. Veitch and Son included well-flowered plants of exoniense, Loder's White, Unknown Warrior, Thomsonii × campylocarpum of rich colour, and Cunningham's Sulphur. In his collection, Mr. G. Reuthe included Hodgsonii, Falconerii and Elizabethiae to show the great luxuriance of their foliage.

The group of plants sufficiently hardy to be grown in the open at Kew provided masses of flower. The first prize group, arranged by Messrs. R. Wallace and Co., was especially effective. In the middle there were floriferous specimens of Countess of Athlone, Bagshot Ruby, General Cavendish and unnamed seedlings of considerable beauty, while the body of the group was made up of Hugh Koster, Brabantia, Lady Stuart of Wortley and other good varieties. In their second prize group, Mr. W. C. Slocock placed several lovely plants of Goldsworth Pink, with Vanity, Mrs. W. C. Slocock, Mrs. May Ashley and a good R. campylocarpum seedling. Messrs. J. Cheal and Sons were third.

The groups of plants not in flower, selected to show their foliage value, were arranged at the far end of the hall and formed an excellent background to those in flower. The first prize group of Messrs. R. Gill and Son was particularly fine, and contained many plants which were decidedly ornamental, even though not in flower. In addition to luxuriant leaves several, such as Mrs. Hamilton and argenteum, have brightly coloured bracts. Messrs. Waterer, Sons and Crisp were second, with a good selection of the hardier hybrids.

The two groups of Azalea plants, shown by trade growers were of very distinct character, and the judges took refuge in awarding equal first prizes to Messrs. J. Cheal and Sons and Messrs. R. and G. Cuthbert for their exceedingly attractive collections. The former included well-flowered plants of coccinea speciosa, Aide, narcissiflora and a number of Japanese varieties. The exhibit of Messrs. R. and G. Cuthbert contained Ghent and Mollis varieties of vivid colouring, and also some good rustica hybrids.

On account of exceptionally severe frosts, during recent nights, which destroyed many buds as well as open flowers, the customary collections were not contributed from Bodnant, North Wales in the Amateurs' Classes, and the competition in the class for a group of plants or cut trusses was confined to two exhibitors. The first prize was awarded to Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Hampshire, for a graceful and floriferous group composed chiefly of the medium-sized and small-flowered sorts. In the background there were large plants of Augustinii, chartophyllum praecox, reticulatum, ambiguum and ciliatum, while in the front there were several very attractive alpine hybrids and seedlings of species collected by Forrest. The second prize was awarded to Admiral A. W. Heneage-Vivian (gr. Mr. W. Leith), Clyne Castle, Swansea, for a very showy exhibit in which prominence was given to many splendid trusses of R. niveum hybrids. He also staged admirable sprays of eximeum, a Thomsonii hybrid of intense colour, Aucklandii, Glory of Penjerrick and some lovely hybrids of R. Falconeri.

There were two smaller groups of cut flowers and in this class the first prize was awarded to J. C. Williams, Esq. (gr. Mr. W. Michael), Caerhays Castle, Cornwall, who staged especially good vases of neriiflorum, Keysii, decorum forms, floccigerum and ixeuticum. On the other side of the hall a handsome exhibit from Colonel R. Stephenson Clarke (gr. Mr. H. Fleming), Borde Hill, Sussex, was awarded the second prize. This included magnificent trusses of Dr. Stocker, a crimson Arborcum, Fortunei × Thomsonii, Queen Wilhelmina and Earl of Athlone. The best twelve trusses of distinct species was shown by the Earl of Stair (gr. Mr. R. W. Rye), Lochinch, Wigtownshire, who included arboreum, Falconeri, bullatum and neriiflorum. A. M. Williams, Esq. (gr. Mr. R. N. Gregory), Werrington Castle, Cornwall, was second. Admiral Heneage-Vivian was first with twelve hybrids and he showed lovely forms of niveum, eximeum, Broughtonii × Fortunei and Glory of Penjerrick. Lady Aberconway, who was second, had good trusses of Richard Gill and Queen Wilhelmina. Admiral Heneage-Vivian was first with four hybrids raised by the exhibitor, showing Singleton Blue, a niveum hybrid, eximeum × niveum and eximeum × Falconeri. P. D. Williams, Esq., Lanarth, Cornwall, was second.

The Earl of Stair, who included lovely trusses of Falconeri and arboreum, had the best three species, and Lionel de Rothschild, Esq., showing splendid trusses of Queen Wilhelmina, Lady Forster and a campylocarpum hybrid, was first for three hybrids.

Single Trusses.

Although the competition generally was not quite so large as last year, there were many very good trusses staged, and in some of the classes the competition was very keen. First prizes were awarded to the following: Sir John Ramsden, Bt., Bulstrode, Bucks., for Loder's Pink Diamond, in the class for the best hybrid, and for a vivid Thomsonii × neriiflorum in the class for a truss of any hybrid raised by the exhibitor, which had not previously been awarded a prize as a single truss; A. M. Williams, Esq., for R. lacteum in the class for the best species, R. russatum, 'Lapponicum' series, R. Baileyi, 'Lepidotum' series, R. oreotrephes and for a truss of the 'Sanguineum' sub-series; P. D. Williams, Esq., for R. neriiflorum, a blood-red Arboreum, a Fortunei variety, R. Morii, 'Barbatum' series, and Hinodigerii (an evergreen Azalea); the Earl of Stair for R. campanulatum, R. taliense and R. arboreum; G. H. Johnstone, Esq., Trewithen, Cornwall, for a beautiful R. Aucklandii × Pink Seedling, trusses of R. fictolacteum, R. Griffithianum, R. irroratum, Azalea Weyrichii and R. Davidsonianum; The Viscountess Falmouth, for R. Falconeri and R. Gill's Triumph; Lionel de Rothschild, Esq., for R. 'Lacteum' series, R. 'Maddenii' series, R. Thomsonii and R. lutescens; N. Vivian, Esq., for R. amoena, R. eximeum × Falconeri and R. Loderi; Gerald E. W. Loder, Esq., Wakehurst Place, Ardingly, Sussex, for R. campylocarpum, and a pink R. adenopodium; J. J. Crossfield, Esq., for R. 'Megacalyx' series, and R. bullatum; Lady Aberconway, for R. rubiginosum, R. Souliei, and R. Richard Gill; J. B. Stevenson, Esq., Tower Court, Ascot, for R. Glory of Penjerrick and R. dichoranthum × neriiflorum.

The best spray of an evergreen Azalea was of Shin Seikai, shown by Admiral Heneage-Vivian. A good blue fastigiatum × Augustinii, shown by A. M. Williams, Esq., was first in the class for a spray of an alpine species. Messrs. R. Wallace and Co. had the best six trusses of hardy hybrids raised by the exhibitor; Lionel de Rothschild, Esq., was first with six vases of Rhododendron foliage. The best foliage Rhododendron plant was a magnificent example of a R. Falconeri hybrid, shown by Admiral Heneage-Vivian. The prize offered for the best Rhododendron plant in the show was awarded to Mr. W. C. Slocock for a shapely specimen of the variety Dairy Maid.

WAKEFIELD PAXTON.

"Errors in Gardening" was the title of an instructive lecture delivered at the meeting of this Society, at the Woolpacks Hotel, by Mr. C. Oglesby, Sandal, on April 20. Mr. J. Howes occupied the chair.

After some preliminary remarks concerning the ethics of mistakes and the resultant knowledge and experience gained—if the gardener cared to assimilate them—the lecturer dealt with the choice of tools, digging, manuring, liming, seed-sowing and planting, and he concluded by saying that many of his successes had been gained by taking note of the errors he had made. A lively discussion followed, in which many of the members gave their views on the various topics dealt with.

Mr. G. Hartley proposed a cordial vote of thanks to Mr. Oglesby for his able lecture, the motion being seconded by Mr. T. Quarton, and supported by Messrs. C. Gibbs, C. T. Wilby and C. Elliot.

NATIONAL PRIMULA AND AURICULA.

(Southern Section.)

April 23 and 24.—This special flower Society held its annual show on these dates, and, having seen it, we wonder why; for, so far as the competitive section was concerned, it was a travesty of a show and unworthy of an association which has any pretentions to the designation of "National." That the exhibits were few, and they could well have been set out on an ordinary dining table, is in itself no matter for stricture; may be there were extenuating circumstances—but there were no signs of intelligent organisation, no indications of the exhibits in the various classes, and it appeared as though the plants were simply dumped down on the staging. How the judges discriminated between them passes our comprehension, but as awards were made we assume they possessed inside information. We have ceased to hope that the Southern Section of this old and one-time highly respected floricultural Society will exercise its legitimate functions of popularising its special flower and of educating the great show-attending public concerning it; and, so far as we could discover, there was no one connected with it present on either day, nor was there any available literature concerning the Society or its flower. If, as we can only conclude, the show which was held at the new Horticultural Hall is the best the Southern Section can produce, we suggest that the best interests of the Section and the flower would be served if its weaknesses were kept private for a season, and its position in the horticultural world seriously considered.

The chief exhibitor and prize-winner of Auriculas was Clive Cookson, Esq. (gr. Mr. W. J. Stables), Nether Walden, Hexham-on-Tyne, but in view of the circumstances, we hesitate to name any plants, except his two premier varieties. His premier Show specimen was Wm. Brocklebank, a very good green-edged sort, while his premier Fancy Auricula was Robb's Fancy. Clifford Burton, Esq., Selsey, was awarded the first prizes for four and for two alpine Auriculas. The first prize six Primulas were small plants of such species as P. frondosa, P. cortusoides and P. hirsuta, shown by R. J. Gummer, Esq., New Barnet. Nearly all the first prizes for Polyanthuses and Primroses were, as usual, awarded to Mr. G. W. Miller, who was also placed first in the class for a group of Primulas or Auriculas, with Mr. R. S. Milford second. Mr. James Douglas set out a non-competitive collection of Auriculas.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on Thursday, April 18, at the Town Hall, Manchester, in conjunction with the Royal Botanical and Horticultural Society of Manchester and the Northern Counties, at the Spring Show, the members of Committee present were Mr. J. B. Adamson (in the chair), Mrs. Bruce, Miss Wrigley, and Messrs. A. Burns, A. Coningsby, J. Evans, A. Keeling, D. McLeod, W. J. Morgan and H. Arthur (Secretary).

Mr. S. Low was invited to sit with the Committee.

First Class Certificates.

Cattleya Susan var. Vestal (*Susanne Hye de Crom* × *Cowaniae alba*).—A large flower of good shape, with pure white sepals and petals, with orange lines in throat; *Odontoglossum Doreen var. Perfection.*—A full, round flower, beautifully marked with crimson. From J. B. Adamson, Esq.

Phalaenopsis Elizabethiae (*amabilis* × *Rimestadiana*).—A very fine form; *Odontioda Mildred* (*Aphrodite* × *Naomi*), a large flower of good shape, deep maroon, lip crimson, bright yellow anthers. From Messrs. A. J. Keeling and Sons.

Odontoglossum crispum var. Osiris.—A large flower of the Doin type, lip spotted with deep crimson. From Mr. John Evans.

Cymbidium Giant Rose (*Alexanderii* × *Schlegelii*).—A finely-shaped flower, soft rose with light crimson spots on the lip. From Messrs. Stuart Low and Co.

Awards of Merit.

Brasso-Cattleya Apollo var. majestica; *B.-C. Doris, Langley var.*; *Dendrobium nobile, Towneley Monarch*; *and Cattleya Linda var. Vestal.* From J. B. Adamson, Esq.

Cymbidium Eagle; *Odontioda Elaine, Jarvisbrook var.*; *Odontoglossum percultum, Jarvisbrook var.*; and *O. amabile, Jarvisbrook var.* From Messrs. Stuart Low and Co.

Miltonia St. André var. Distinction, and *Cypripedium Mona var. Virginale.* From Messrs. A. J. Keeling and Sons.

Cultural Certificates.

To Mr. A. Burns, for Miltonia Phalaenopsis, and Sophronitis grandiflora; Mr. J. Howes, for Dendrobium Wardianum and D. infundibulum; and to Mr. Selby, for Lycaste Skinneri.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, showed a group to which a Gold Medal was awarded. It contained Cattleyas in variety; Odontoglossum crispum var., O. Faith, O. Diamond, O. Meredithiae, O. Excellens, and O. Colossus; Dendrobium nobile var. alba, D. Thwaitesiae and D. thyrsiflorum; Bifrenaria Harrisoniae, Angraecum Sanderianum, and Masdevallia ignea.

Messrs. A. J. Keeling and Sons, were also awarded a Gold Medal for a group of Cattleyas in variety; Odontoglossum Miguelito and O. Rolfeae; Odontioda Queen Mary, O. Brilliant, O. Brewii and O. Gladys; Epidendrum Endresio-Wallisii; Miltonia Charlesworthii, M. Lena and M. Venus; Phaius Sanderiana; Dendrobium atro-violaceum and Trichopilia suavis. Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, staged a group to which a Large Silver-gilt Medal was awarded. They showed Lycaste Skinneri vars. Rosalba, Pax, Robin, and delicatissima, and L. lassiglossa; Laelio-Cattleya Canada; Brasso-Cattleya Cliftonii var. magnificum; Miltonia Bleueana var. Reine Elizabeth, and Masdevallia Kimballiana. Captain W. Horridge (gr. Mr. A. Coningsby), Bury, was awarded a Large Silver Medal for a group of Dendrobiums; Odontoglossums and Odontiodas, Laelio-Cattleya Beatrice, and Sophronitis grandiflora.

Mr. John Evans was also awarded a Large Silver Medal for a group of Cypripediums in variety, including C. Alva, C. Christopher and C. Boltonii; Cymbidium Erica Sander and C. Joy Sander, and Lycastes.

Messrs. Stuart Low and Co. showed Cymbidium Alexanderii var. roseum and Odontioda Sanderae. Mrs. Hollas (gr. Mr. Selby), Grimsaigh, sent Lycaste Skinneri; and Mr. D. McLeod exhibited Odontoglossums in variety.

READING GARDENERS'.

The Annual Supper and Smoking Concert of this Association was held in the Abbey Hall, by kind permission of Messrs. Sutton and Sons, on the evening of April 10, and proved a most enjoyable and successful affair. The President, Mr. Frank E. Moring, presided. After the loyal toast had been given, a splendid musical programme was enjoyed. During the proceedings, the toast of "The President" was given by Mr. Councillor T. Waldron, and was received with musical honours. The tables were beautifully decorated with Cyclamens, Tulips and Daffodils by Mr. E. J. Dove.

Obituary.

William Richard Carles.—A fortnight ago, there passed away in his sleep, at the age of eighty, one to whom all lovers of beautiful flowers will ever owe a great debt—William Richard Carles. On leaving Marlborough in 1867, he entered the Chinese Consular Service, and as Consul General in 1900 rendered conspicuous service by his defence of Tien-Tsin against the Boxers. For this he received the C.M.G. He spent one of his furloughs in Corea, and came across the Viburnum which now carries his name—Viburnum Carlesii, and was able to send home, I believe to Kew, material to which the plants now so widely spread owe their existence. Such a benefactor deserves to be remembered. *An Old Marlburian.*

John M. Hunter.—We learn with regret, from an American contemporary, of the passing of Mr. J. M. Hunter, who, before going to America in 1884, occupied several important horticultural positions in this country. He was born at Seaham, Durham, and he started gardening at the age of twelve, in the gardens of the Marquis of Londonderry, at Seaham Hall. From there he went to the John Harrison Rose Nurseries at Catterick Bridge, and later he returned to private service at Sockburn Hall, Durham. His last position in this country was that of Superintendent of Harrogate Cemetery. He and his wife, with their four children, emigrated to the United States, where, after filling several important horticultural posts, he finally started business as a landscape gardener and florist at Englewood, New Jersey. Within a few years, however, his health broke down and he finally sold his business and settled down in retirement in a home he bought at Long Beach, California. Later, he sold this property and returned to New Jersey to help his son start a florist's business at Leonia, but he never recovered his good health, and two weeks before his death (on March 29) he was stricken with apoplexy while working in the greenhouses, and to this he succumbed. He died at the age of seventy-seven years, respected by horticulturists throughout the States, and is survived by his wife, two sons, and three daughters, to whom we extend our deep sympathy.

Dr. Robert Ridgway.—Horticulturists in general are familiar with the name of Dr. Robert Ridgway, as the compiler of what may be termed the standard work on colour—*Ridgway's Color Standards and Color Nomenclature,* and will regret to learn of his death, at the latter end of March, at the age of seventy-eight. Dr. Ridgway, who was born at Mount Carmel, Illinois, in 1850, was a prominent American ornithologist; he was the author of many works connected with bird life, and belonged to practically every important ornithological society throughout the world.

ANSWERS TO CORRESPONDENTS.

Filling Hollow Trees.—*C. F. D.* A plastic mixture of cement is about the best filling for holes in stems of trees, but the holes must be thoroughly cleaned before the material is placed in position, and then it must be pressed firmly into place.

"Fire" in Tulips.—*J. S. B.* The Tulips are affected with "fire," due to Botrytis tulipae. Remove and burn all infected bulbs; collect and burn diseased foliage. The soil surounding infected bulbs should be taken away and buried in some other part of the garden where bulbs are never grown. Lift all the bulbs after the foliage has died down, and examine them for sclerotia (dark resting-bodies of the fungus) on outer scales and discard all those with sclerotia on them. Do not plant Tulips on infected ground.

Hyacinth Bulb Badly Ripened.—*W. W.* The Hyacinth bulb was quite healthy. The trouble is that the basal plate had become hardened and no root system was evident. This trouble occurs in Hyacinth bulbs through defective drying. The basal plate becomes covered with a corky layer through which the growing points of the roots are unable to penetrate. It is suggested that the bulbs be lifted after cutting off the flower spike and have the hard layer lightly pared off with a sharp knife, after which replant in good soil. This may induce root formation.

Names of Plants.—*A. E. W.* Probably Tulip Scarlet Emperor.—*A. J. D.* 1, Cupressus Lawsoniana; 2, Cupressus Lawsoniana var. compacta; 3, Thuya orientalis.

Privet Hedge Overhanging.—*M. T.* If B. allows his hedge to overhang A.'s land, it constitutes a nuisance, and A. should give B. formal notice to abate such nuisance by cutting back the hedge, and inform him that, in the event of his not doing so within a reasonable time, A. will himself abate the nuisance and charge B. with the cost.

Perpetual Carnations.—*B. N.* Your trouble may arise through two causes:—Firstly, it may be due to overfeeding during the dull months of the year, as this would cause sappy growth; secondly, your young growth may be attacked by thrips, these pests being very partial to the variety Carola, especially overfed plants. This latter seems the likely cause of your trouble, for you state the variety Winter Glow shows no signs of forming flower buds. This variety is in no way related to Carola. Spray the tips of your plants with Nicotine, using half-a-teaspoonful to four gallons of water. Spraying must be persevered with until the stock is cleared of the pest. Corola requires more warmth during the winter months to open its flowers than most of the other varieties.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 52·9°.

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, May 8, 10 a.m. (Greenwich time). Bar. 29·9. Temp. 54°. Weather, Cloudy.

Phosphatic Fertilisers.

BROADLY speaking, it may be stated that the agricultural land of the world is in a chronic state of hunger. This land-hunger is primarily hunger for nitrogen, but in a scarcely less degree it is hunger for phosphates. Somehow or other the nitrogen and the phosphates put into the soil always disappear, either in the crop and ultimately in the animal which feeds upon it, or into the depths of the ocean in the case of phosphates, and into the ocean of air in the case of nitrogen. At all events, the nitrogen which the land wants so much occurs to the extent of countless millions of tons in the earth's atmosphere, where it exists "remote, unfriendly, alone." These facts have long been recognised and have led in the past three-quarters-of-a-century to increasingly intensive manuring. The nitrate deposits of Chile and the nitrogen residues won from coal in the process of manufacture of coke and gas were for long the chief sources of nitrogen fertilisers. Now these supplies are being augmented from the nitrogen of the atmosphere, and on so vast a scale is this manufacture of nitrogen-compound fertilisers carried on that for the first time in the history of the world the earth's vegetation bids fair to be sufficiently fed. All through the past ages it has suffered from nitrogen hunger. Similarly, the plant has, in the past, had to subsist on precarious rations of phosphates, and deficiency both of nitrogen and phosphates has limited the luxuriance of vegetation. A third element essential to plants and not infrequently present in insufficient quantities in soil is potash, and hence it is that anyone well practised in cultivation always thinks of fertilisers in terms of N.P.K., that is, nitrogen, phosphates and potash. Compound fertilisers consist, of course, of suitable mixtures of material composed of these three elements and in general, where intensive cultivation is practised, as in the garden and under glass, a compound fertiliser containing the right proportions of these materials is employed. But in agriculture, where lower yields are expected, and where costs of production are closely scrutinised, it is often advisable for the farmer to apply the one of these three types of fertiliser which his soil and the crop to be grown in it most requires. For each of these three essential elements serves special functions. Thus, as stated in the recently issued Leaflet No. 394,* phosphatic fertilisers serve five purposes. They bring about earlier development of the seedling plant, encourage root growth, prevent rankness of growth which occurs if an excess of nitrogen is present in the soil, hasten ripening, improve quality in grain and increase the feeding value of fodder crops. Phosphatic fertilisers are of many kinds—raw bones, bone-meal, steamed bone-flour, dissolved bones, superphosphate, basic slag and mineral or rock phosphates, to which list must be added the more recent and not yet generally available ammonium phosphate—a fertiliser which supplies in concentrated form both nitrogen and phosphates. Gardeners are fond of using bone-meal, which contains the gelatine of the natural bone, but, in agriculture, superphosphate is chiefly used. Superphosphate is, or should be, an ingredient of every Potato manure; it is good also for roots and cereals such as Barley after roots. Basic slag, as well as superphosphate, is used largely in grassland, and has done much to improve pasture both in this country and in Australia and New Zealand, where phosphatic fertilisers are being used on an enormous and ever-increasing scale. When basic slag is to be used as a source of phosphates it is important for the purchaser to make sure that it is of the right kind, that is, one which contains not less than sixty per cent. of its phosphoric acid in a form which is soluble in a two per cent. solution of citric acid. Fineness of grinding is also important, and anyone contemplating purchasing this fertiliser should study the pamphlet to which reference has already been made. Lastly, finely ground mineral phosphates have the merit of cheapness and are found to be suitable in a moist climate, and on soils very deficient in phosphates, and also on soils which are rich in organic matter and not abundantly supplied with lime. Everyone interested in the use of artificial fertilisers should procure the sectional volume of collected Leaflets No. 8, issued by the Ministry of Agriculture under the title "Manures and Manuring." It may be had for 9d. post free, direct from the Ministry, 10, Whitehall Place, London, S.W.

The King: A National Thanksgiving.—Now that the King has happily recovered from his severe illness there is a widespread feeling that the time has come for the nation to give expression to its gratitude by making donations to hospitals and various charitable institutions. Already one of the regular supporters of the Royal Gardeners' Orphan Fund has adopted the suggestion and, as his personal gift, has increased his usual £10 to £100 to be added to the Chairman's list at the Annual Festival Dinner of the Fund at the Savoy Hotel, London, on Wednesday next. It is not within the means of everyone to give so liberally, but we suggest that all whose pleasure and profit are in horticulture might well show their loyalty and gratitude by making a gift, according to their means, to this deserving charity. Donations of any amount would be gratefully acknowledged either by Mr. Samuel Wallrock, The Manor House, Stanmore, who will preside at the Dinner, or by the Secretary, 19, Bedford Chambers, Covent Garden, W.C.2.

Chelsea Show Arrangements, 1929.—The Royal Horticultural Society's great Spring Show will be held at Chelsea on Wednesday, Thursday and Friday, May 22, 23 and 24. On the first day there will be a private view for Fellows and their friends from 8 a.m. to 12 noon, and on Thursday, May 23, from 8 a.m. to 10 a.m. Only Fellows' and Associates' tickets will admit to the private view, but transferable as well as non-transferable tickets may be used. There will be no admission by payment on Wednesday, May 22, until 12 noon, and on Thursday, May 23, until 10 a.m., when the show will be opened to the public. Those who propose to submit new or rare plants for certificate should remember that the Committees will meet on Tuesday, May 21, the Joint Iris Committee at 4.30 p.m., and the Fruit and Vegetable, Floral A. and B., Orchid, and Narcissus and Tulip Committees at 5 p.m. All plants, etc., for certificate must be entered with the Secretaries of the respective Committees by 4 p.m., new Bearded Irises being entered with the Secretary of the Joint Iris Committee by 3.30 p.m. The Secretaries of the Committees will be in attendance to receive entries from 10 a.m. Vans will not be admitted to the Show grounds on Tuesday, May 21, after 2 p.m.

The Iris Society's Show.—The third Annual Show of this progressive Society will be held this year in the Royal Horticultural Society's new hall, on Thursday and Friday, June 6 and 7. This is the first occasion on which the Iris Society has attempted a two days' show, and every effort is being made to make it a success. In an endeavour to add further interest to the show, the Society is inviting deputations and exhibits from Continental and American Iris growers. The show will be opened at 12.30 p.m. of the first day by His Excellency the French Ambassador, and at 4.30 p.m. on the same day the Iris Society, the Royal Horticultural Society, and the English Speaking Union, will entertain members of the Garden Clubs of America to tea. At 11.30 a.m. on the second day, June 7, there will be a discussion on "Garden Irises," to be opened by Mr. R. W. Wallace, and at 3 p.m. Mr. P. R. Barr will deliver a lecture on "Iris Species for the Garden." Among the most important medals and trophies offered at this show are the Silver Medal of the American Iris Society, for the best twelve spikes of Bearded Irises of American origin or raising; the Iris Society's Challenge Cup (presented by Mrs. Philip Runciman), for the best exhibit of Irises staged by an amateur; the Gordon-Lennox Challenge Cup (presented by Lady Algernon Gordon-Lennox), for the best exhibit demonstrating the decorative value of Irises, on a space not exceeding seventy-five square feet (open to all); and the Christie-Miller Challenge Cup (presented by C. W. Christie-Miller, Esq.), for the best collection of Iris species, arranged in a space not exceeding thirty square feet. The Schedule may be obtained from the Hon. Secretary of the Society, Mr. G. L. Pilkington, Lower Lee, Woolton, Liverpool.

Cactus Society of America.—There has recently been a "boom" in Cacti and Succulent plants in America, and at all the principal shows these plants have occupied prominent positions, with the result that they now enjoy a fairly widespread popularity in the United States. One of the direct outcomes of this movement is the inception of the Cactus and Succulent Society of America, at San Fernando, California. A tract of dessert land, 1,000 acres in extent, situated in southern California, has been offered to this Society, as a donation, for the establishment of a garden, while a library is in course of formation and the issue of a monthly publication is assured.

---

* *Phosphatic Fertilisers*; Leaflet No. 394; Ministry of Agriculture, 10, Whitehall Place, London, S.W.

Legacies to Gardeners.—Under the will of The Right Hon. Constance Emily, Baroness Eversley, of Abbotsworthy House, Kingsworthy, Winchester, who died on February 27, at the age of seventy-eight, Mr. Henry Spencer Miller, her head gardener, receives the sum of £1,000; Mr. Frederick Simmonds, gardener, receives £300; Mr. George Gregory and Mr. Ernest Young, under-gardeners, £100 each, respectively: and Mr. George Pinton and Mr. William Berry, both under-gardeners, £50 and £20 respectively.—The Right Hon. Samuel Hope, first Baron Hollenden, of Grosvenor Square, W., who died on February 18, left £100 to his gardener, Mr. R. G. Pringle, and a life annuity of £26 to the widow of his late gardener, Mr. Charles Davis.—Mr. Frederick M. Dickson, J.P., of Levenside, Haverthwaite, Ulverston, Lancashire, who died on February 3, left £200 to his gardener, Mr. T. Wilson, if in his service and not under notice at the time of his decease.

The Carnation "Year Book."—The 1929 issue of this official organ of the British Carnation Society will be welcomed by the members as, besides the usual business matter appertaining to the Society, it contains several instructive and interesting articles by competent Carnation authorities. For instance, Mr. C. Engelmann briefly outlines the progress of the Perpetual-flowering Carnation; Mr. L. J. Cook contributes a problematical article entitled "The Unexpected — with Carnations"; and Mr. T. Stevenson discourses on "What should be aimed for in New Carnations." Mr. Montagu C. Allwood gives "Some Hints on Perpetual-flowering Carnations," and Mr. F. W. Allsworth, the Hon. Secretary, deals with Carnation Growing at Kew and in Hyde Park. The publication is attractively illustrated and well printed. The joint-schedule for the summer and autumn shows of this Society, to be held on July 18 and 19, and November 20 and 21, respectively, has also been issued.

New Canadian Flowers and Fruits.—The Canadian Horticultural Council announces that twelve new varieties of plants were received for recording during 1928. These include one plant each of Geranium Nora Baldwin, Lilac Dr. F. E. Brethour, Astor Bosco Belle, Rose Canadian Jubilee, Crab-Apple Confederation, and Apple Golden Sunset. Two plants each were recorded of Iris Alice Aileen and I. Hochelaga; and of Strawberry What-a-flavour and Confederation; and three plants of Dahlia Kathleen Salmon, Mitchell's Favourite and Jean Trimbee.

Japanese Cherries at Kew.—Few trees in the outdoor garden rival the Japanese Cherries in their freedom of flowering and attractive beauty. The abundance of blossoms produced annually, even on small specimens three or four feet in height, may be attributed to the fact that only two or three of the single forms produce fruits, unless hand pollenated. In Japan, named varieties are numerous, but a selection of twelve or fifteen varieties will give a representative display of their beauty in British gardens. The flowering season extends over a period of five or six weeks, beginning with Prunus yedoensis early in April, while one of the last to fade, towards the end of May, is P. serrulata var. longipes; the Japanese name of this beautiful double-flowered Cherry is Oku-Miyako. This spring the flowering season at Kew is ten or fourteen days later than usual. About the middle of April P. Lannesiana var. Yemari opened the first of its delicate, single, pink blossoms. This was closely followed by P. serrulata var. spontanea with a profusion of small, white blossoms, and P. Lannesiana var. amabilis, a very attractive, semi-double, pink variety. One of the most distinct and showy is P. serrulata, with wide, out-spreading branches thickly clustered with double, white flowers. In direct contrast is P. Lannesiana var. erecta—Amonogawa of the Japanese—upright in habit, the branches studded with single, pink blossoms. Other good sorts are P. serrulata var. Sekiyama, the popular Hisakura of nurseries, with bronze-tinted foliage and rich rosy-red flowers; P. serrulata var. Fugenzo, better known in gardens as James H. Veitch; P. Lannesiana var. grandiflora—Ukon of the Japanese—with pale yellow blossoms; P. Lannesiana var. albida, a very free-flowering Cherry with large, fragrant, single, white blossoms; P. Sieboldii (syn. P. Watereri), slow in growth, with attractive, double, pink blossoms; and P. serrulata var. rosea—Cheal's Weeping Cherry—a beautiful weeping variety with double, rose-pink flowers.

Mr. Samuel Wallrock.—The Royal Gardeners' Orphan Fund has always been fortunate in its Chairmen for the Annual Festival Dinners, and, this year, the Committee is to be congratulated on having persuaded Mr. Samuel Wallrock to preside at the Savoy Hotel next Wednesday. In a sense, Mr. Wallrock is one of fortune's favourites, for he was able to retire from active business while still in the forties, with more than a competency. Those who knew him best were convinced that the retirement would be only temporary, and that the very qualities which enabled Mr. Wallrock to be in a position to follow the dictates of his fancy, would prevent him settling down to a life of comparative leisure. And this proved to be so, for within a comparative short space of time Mr. Wallrock took up his work again. From this it will be realised that he is gifted with almost unbounded energy, and brains and enterprise far above the ordinary, together with whole-hearted enthusiasm for all that he undertakes. In a comparatively short time, Mr. Wallrock has been many things besides a money-maker—with regard to the latter, it is enough to state that, among other activities, he was responsible for the conversion of a part of Mayfair into business premises. He has been President of the Incorporated Society of Auctioneers and Landed Property Agents. He is a member of the Worshipful Company of Feltmakers and a Freeman of the City of London; for many years he held a commission in the 2nd City of London Fusiliers, and has been associated with many other affairs; in fact, his activities have made him one of the most widely reported men in the country. As an amateur gardener Mr. Wallrock is becoming increasingly well-known for the excellence of his exhibits at various shows in the provinces and, more recently, his large collections of grand Cinerarias and Schizanthuses at the R.H.S. meetings. He is still actively engaged in the making of a large garden at Stanmore, in Middlesex, and this is fast becoming one of the most interesting in the country. Another of Mr. Wallrock's hobbies is the liberal support of deserving charities and, being a family man—and a gardener—the Royal Gardeners' Orphan Fund makes an irresistible appeal to him, consequently he has devoted a considerable amount of time towards the success of the Chairman's List for the Festival Dinner on Wednesday, May 15.

MR. SAMUEL WALLROCK.

New Rose Garden for Guildford.—Thanks to the initiative of the Guildford and District Rose Society, Guildford is to have its first public Rose Garden. The situation is in the old gardens attached to the mansion in Stoke Park. The property was purchased by the Corporation four years ago, but owing to a lease, the gardens have but recently been taken over. The President of the Rose Society, Councillor William Harvey, is also the Chairman of the Public Parks and Pleasure Grounds Committee, which happy combination may have had something to do with negotiations between the Society and the local authorities. The offer of the Rose Society to prepare, plant and be responsible for the maintenance of a Rose Garden found a ready and grateful acceptance. A good deal of spade work was needed to reclaim a section that had run to waste in the old gardens, but about three-quarters of an acre has been reconditioned and three large beds have been planted with several hundreds of Roses in many varieties. This generous and public-spirited work has been carried out without any charge on the funds of the Society. The planting and pruning has been done voluntarily, but with such adverse climatic conditions to contend with, and late planting, no great display is expected this year, although it is hoped that these gardens, charmingly situated, will eventually become not only a beautiful and restful retreat for the general public, but also a place where Rose-lovers will be able to learn a great deal about Rose cultivation by seeing the varieties growing that have been found to do best in this neighbourhood, and by watching the various operations of rose culture in their due seasons. Remembering Mr. Harvey's well-known love for Roses, this is probably but the beginning of the Society's public work in this highly favoured town.

Cacti and Succulent Plants at Chelsea Show.—A special and unique feature of the Chelsea Show will be an extensive display of Cacti and Succulent plants, arranged in realistic fashion by Mrs. Sherman Hoyt, of Pasadena, California. This enthusiastic lady had a somewhat similar exhibit in New York in 1928, and one this year at the Boston Centennial Show, where it won the highest awards. A considerable number of the plants, with natural stone and sand, are already in this country, the plants being in charge of Mr. Baggeson; other plants are following. The cost of carriage alone is, we believe, not less than £300. A special tent will be devoted to the exhibit at Chelsea, and powerful electric lamps will produce the necessary effect of brilliant light should the sun prove unkind. After the show the whole of the exhibit will be presented to the Royal Gardens, Kew.

Proposed Potato Pool in Scotland.—The National Farmers' Union of Scotland has taken a definite step towards the establishment of a trading Society for the disposal of Potato crops north of the Tweed. At a meeting held at Stirling, on April 25, the scheme was submitted by Mr. James Lennox, Redhills, Methven, and was favourably received. According to the provisions, members of the Society are to contract for a period of three years to sell all their crops through its agency, but unless 20,000 acres are guaranteed, the scheme will not be put into operation. It is hoped, however to get 50,000 acres, which represent fully a third of the land under Potatos in Scotland. The pool is to determine the time and sale of the crops, and it is proposed to market the maincrop varieties in two portions, *i.e.*, the first from October to January, and the second from February to May. Part payment is to be made in advance to growers, and the ultimate price would be the average obtained for particular varieties under a graded designation mark, ascertained over the whole season. Members on entering into contracts would be required to state their acreage, and undertake not to sell any produce outside of the pool without consent. The pool, on the other hand, is bound to relieve members of their whole crop, provided it does not exceed the acreage stated in their contracts. Each member would be required to subscribe shares in the Society of 40s. to 50s. per acre, estimated on the average of the past three years. As an illustration of the saving in transport costs, Mr. Lennox reckoned that they would get better railway terms for bulk traffic, and by chartering boats to carry seed sets to England they would save from £2 to £3 per acre on the present costs.

Cavendish Family and the Royal Horticultural Society.—The old connection of the family of Cavendish with the Royal Horticultural Society has been resumed by the appointment of the Marquess of Hartington to the Floral Committee. Lord Hartington, eldest son of the Duke of Devonshire and M.P. for West Derbyshire, is a keen gardener, and both in his own garden at Churchdale Hall, Derbyshire, and also at Hardwick Hall and Chatsworth he occupies a great deal of his time in the cultivation of shrubs and trees of all kinds. It was the sixth Duke of Devonshire who was President of the Society for twenty years[*] (1838-58). He employed Paxton (afterwards Sir Joseph, and one of the founders of *The Gardeners' Chronicle*) to build the immense glasshouse at Chatsworth which led to Paxton being employed to erect the building in which the Great Exhibition of 1851 was held in Hyde Park, and which was afterwards removed to Sydenham and reconstructed as the Crystal Palace. The same Duke of Devonshire first leased part of his estate at Chiswick (close to Turnham Green) to the Royal Horticultural Society, where the Society maintained a garden and held famous exhibitions for many years. Although these old gardens have long since disappeared, Chiswick House and its gardens still remain, and have been recently acquired from the Duke of Devonshire, for the use of the public, by the Brentford and Chiswick Urban District Council, whose Parks and Open Spaces Committee is under the Chairmanship of Mr. Charles H. Curtis, of *The Gardeners' Chronicle*, at one time Assistant Superintendent of the R.H.S. Gardens, Chiswick, under Mr. A. F. Barron.

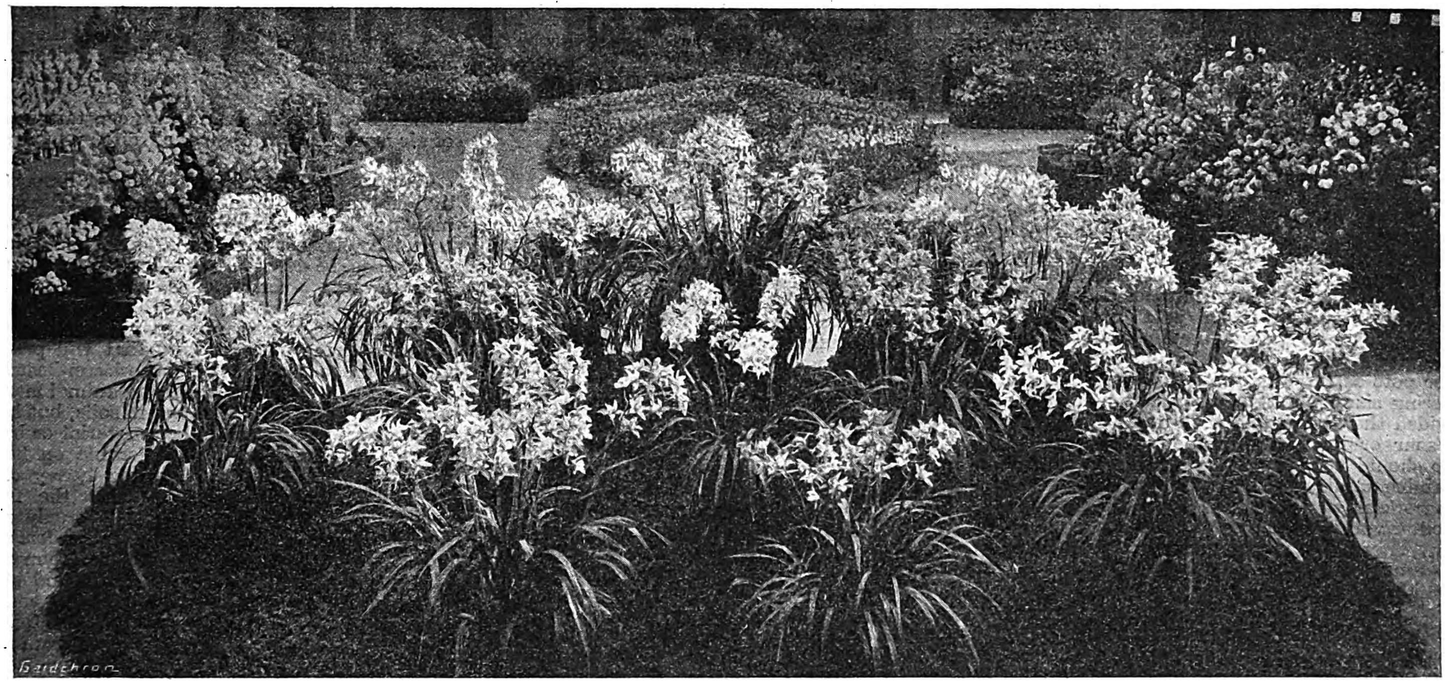

FIG. 170.—MESSRS. SANDERS' GOLD MEDAL EXHIBIT OF CYMBIDIUMS AT THE R.H.S. MEETING OF APRIL 23. (see p. 310.)

Fritillaria karadaghensis.—Messrs. R. Wallace and Co. write :—" A few weeks since you illustrated Fritillaria karadaghensis, from specimens we showed before the Royal Horticultural Society (see Fig. 107, p. 221). We would like to give credit where it is due. The discoverer of this new species was Mr. George Egger, who handed the specimens to Mr. Gilliat-Smith, who sent them on to Kew."

Chelsea Physic Garden.—Grave concern has been aroused among those responsible for the welfare of the old-established Chelsea Physic Garden by the proposal to erect a power station at Battersea, as it is considered that, if the proposal is put into effect, the difficulties already attending the growing of plants in this garden will be increased a hundredfold, owing to the sulphurous fumes which will be released into the atmosphere.

North-east Coast Exhibition.—As recently announced in *The Gardeners' Chronicle*, this exhibition will be opened by H.R.H. The Prince of Wales, on May 14. Although practically every branch of industry in the north-east and surrounding districts is well represented, other attractions have not been neglected; art, forestry, and horticulture have been extensively catered for. In the forestry section, not only are the flowering trees and shrubs represented, but a quantity of ornamental, evergreen and deciduous trees and shrubs have been skilfully planted for effect, and there is an extensive forestry nursery with trees from the seedling stage up to a size for general planting. The horticultural exhibits are now well forward, considering the unfavourable weather conditions experienced during the whole of this year. The rock garden arranged by Messrs. Lawrenson, the herbaceous borders by Messrs. Harkness and Sons and Messrs. Gibson and Co., and the display by Messrs. Kent and Brydon, are all good. There are beds and borders of Roses at every turn. Messrs. Finneys are responsible for the grass plots in the large square in front of the main pavilion. Messrs. Dobbie and Co. are occupying a considerable space with hardy and other attractive plants, while the Violas from Messrs. Harrison, a local grower of note, are already making a good display. The lake has been increased in size, and the sides are being planted with numerous flowering and ornamental shrubs broken here and there by rockeries; this will be of permanent interest to the local inhabitants for years to come. Two horticultural shows are to be held, the first on July 4, 5 and 6; the schedule for this show is now ready, and any particulars respecting the shows may be obtained from Miss A. M. Kelly, at the North-east Coast Exhibition, Newcastle-upon-Tyne, who is to be congratulated on the work she has carried out under the trying climatic conditions she has had to contend with.

Appointments for the Ensuing Week.—TUESDAY, MAY 14 : Jersey Gardeners' Society's meeting; Manchester and North of England Orchid Society's Exhibition.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Mr. Groom's Tulips.*—These are just now in perfection, and we can promise our readers that a sight of them will amply repay a visit. The best bed, 120 feet long, and containing not less than 2,000 flowers, is as fine as we have ever seen it. We observed the following favourite sorts in good condition, viz. :—Bybloemens : Victoria Regina, A. Addison, Captain Cook, Roi de Siam and Violet Alexander. Roses : Duchess of Sutherland, Countess of Wilton, Fleur de Marie, Michael Angelo, Claudiana and Catalani. Bizarres : Duke of Devonshire, Marshal Soult, Polyphemus, William the Fourth, Prince of the Netherlands, Catafalque, Dr. Horner and Prince of Wales. Among novelties were Miss E. Seymour, a good rose ; Themis, a Bybloemen ; and Mr. F. Perkins, Duke of Wellington and Marquess of Bristol, Bizarres. Of these and a few others we hope to give some account hereafter. The beds in the open ground are now at their best, and being spread over a large surface of ground they make a fine display. They have not been injured in the least by frost, and of failures there are scarcely any. A fine bed of Rose Eclatante, a deep red, double kind and scented, was especially remarkable ; this is a sort which should not be lost sight of by growers of early Tulips. *Gard. Chron.*, *May* 13, 1854.

Publications Received.—*Rose Growing*, edited by J. N. Hart ; crown 8vo., pp. 128, illustrated ; Messrs. Ward, Lock and Co., Ltd., Warwick House, Salisbury Square, E.C.4. Price 1s. net.—*Blonde or Brunette : the Art of Hair-dyeing*, by H. S. Redgrove and G. A. Foan ; pp. 182, well illustrated ; Messrs. William Heinemann (Medical Books), Ltd., 99, Great Russell Street, W.C.1. Price 7s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Cymbidiums.—These have been making a grand display of bright and variously coloured flowers for many weeks. The lasting properties of the flowers are well-known, as they keep perfect for many weeks, both on the plant and when cut and placed in water; furthermore, these Orchids are of robust habit and easily grown, for they thrive under cool treatment, with a minimum temperature of about 50°, with ample ventilation, a moist and buoyant atmosphere, and light shading from strong sunshine. If they are grown with other cool-house Orchids, the best results are obtained if they are given a separate section so that the necessary light and air can be admitted to assist the ripening of the pseudo-bulbs and to ensure successful flower production. Well-rooted plants should not be allowed to remain dry at the roots for long periods, and they need copious supplies of water each time the soil appears dry, when the plants are developing and bearing their flower spikes. Red spider often attacks the leaves if dry conditions are maintained during hot weather. The syringe should be used on all favourable occasions to keep this pest in check, and should it gain a hold on the leaves, sponging with soapy water is the best remedy; strong solutions of insecticide permanently injure the foliage and should be avoided. The small scale insects which often infest the pseudo-bulbs increase rapidly and quickly spread to the foliage and retard growth if not removed so soon as detected. Cymbidiums resent much root disturbance. The small plants, such as seedlings and propagated plants, should be potted on into slightly larger pots as they require it, but specimens of flowering size do not require annual repotting, provided the drainage is good and the compost not sour or impoverished; any repotting of these should be done with a view to the plant remaining undisturbed for two or more years. This work may be done safely after the flowering period, when the plants are commencing to grow again. Remove the old soil and the decayed roots and useless back pseudo-bulbs; the latter, if sound, may be potted up if an increase of stock is desired. A good, substantial compost should be used, consisting of three-parts good loam, one part finely cut fibre, and plenty of finely crushed crocks; if this is used in a dry condition it can be worked easily among the fleshy roots without injuring them, for the roots are easily damaged when a potting stick is used. A little extra shading should be given to newly-potted plants, but very little water will be required at the roots until they are well established in the new soil, when increased supplies may be given.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Planting Forced Strawberries.—When these plants have not been unduly weakened by hard forcing, they are excellent for planting in a well-prepared piece of ground in the fruit quarters. They should, of course, be hardened off gradually by giving them the protection of a cold frame and a good supply of water. Should the plants show signs of red spider or mildew, a few of the older leaves may be removed and destroyed, and the remainder given a thorough dusting with flowers of sulphur. When planting, break the ball of soil about the roots, and remove any crocks and a portion of the caked surface soil. If this is done, the roots will take quickly to the new soil. Plant them deeply and firmly and give one or two good waterings to settle them in. Under favourable conditions they will produce a crop of fruits in early autumn—just that extra dish of dessert fruits which is appreciated at that time.

Black Cherry Aphis (*Myzus cerasi*).—Even when the winter spraying for the destruction of the eggs of this aphis has been well carried out, there is always a small proportion hidden in cracks and other sheltered nooks, which escapes. Under favourable conditions these eggs hatch out, and the lice multiply with such rapidity as to cover completely and destroy the young growing shoots. These insects, all of which are females, have the power of producing living young, and continue to do so for many generations during the summer months. Winged forms appear in July, when they leave the Cherry for some other host plant, returning in autumn, when the male and the egg-laying females appear. The progeny from the over-wintered eggs hatched in spring, invariably, like most other aphidae, attack the under surfaces of the leaves, and by sucking the sap from the cells cause the leaves to curl backwards, and so form a protecting enclosure. It is of the utmost importance, therefore, that the trees should be examined every few days for the appearance of this pest, or that we anticipate the attack by spraying with some good soapy mixture. Spraying should be carried out before the leaves begin to curl. The most effective spray to apply at this time is one of soft soap and nicotine, 8 lbs. to 10 lbs. of the former, and five ounces of the latter, to one hundred gallons of water. This spray should be applied with some force, and particularly to the under surface of the leaves. Nicotine is now comparatively cheap—16s. per pint of twenty fluid ounces—and should be employed largely against all forms of plant lice.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Pruning Flowering Shrubs.—Flowering shrubs are, in the majority of cases, a few weeks later in blossoming compared with former years. Those flowering on the previous year's wood should be attended to as they pass out of bloom. The well-known Forsythias are good examples of the type requiring this treatment. By pruning these annually, a plentiful supply of vigorous, young growths is encouraged which will flower freely the following spring, and this treatment also tends to keep the plants shapely. F. suspensa is probably the most popular and is valuable for training on walls. At Wisley it has been allowed to ramble through the branches of a Pine tree, and the effect is very attractive when its golden bells are produced freely, with the dark foliage of the Pine as a foil. The best of the Forsythias for planting in beds or in the shrubbery is F. intermedia var. spectabilis, which is of erect and dense habit and does not require hard pruning; its flowers are of pleasing, deep rich yellow. F. i. var. densiflora is also worth including in a collection. To the observant, it is not difficult to recognise those shrubs that require treatment similar to that afforded Forsythias to get the best results. They include the sweetly-scented Chimonanthus fragrans which, if grown on a wall, should be pruned in February or March; and the homely Jasminum nudiflorum, so welcome on cottage walls in early spring, which should be encouraged to make long growths by pruning when flowering has finished. Likewise, Clematises of the C. montana group are most attractive if the necessary attention can be bestowed on them as they pass out of bloom. Much dead wood will have to be removed where large collections of shrubs are grown, owing to the past severe weather, but it is better to defer this work until milder and more genial conditions prevail, when the extent of the damage done may be fully ascertained.

Herbaceous Plants.—The stronger-growing herbaceous plants are now far enough advanced to have the weaker growths removed. This is a very necessary operation if good spikes of flowers are desired from such subjects as Delphiniums, Asters and Phloxes. Rapid growth will be made by many of these plants from now onwards, and close attention must be given to staking. For the more bushy sorts nothing is so satisfactory as Hazel twigs. These, if of the right size, and put in and around the plants at an early stage, so that the young growths grow through them, give the whole an extremely natural effect. For such subjects as Delphiniums, Liliums, and the taller-growing Asters, Bamboo or Hazel stakes are most suitable.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield Surrey.

Forcing Cherries.—Houses in which the earliest varieties of Cherries are approaching the ripening stage must be kept somewhat drier on dull or wet days, and ventilated as freely as may be consistent with the swelling of later fruits when the weather is fine. If growing in pots, very careful watering is necessary to ensure that they do not get too dry or too wet at the roots. Trees in borders, if well-watered and mulched shortly before the fruits change colour, should seldom require any more moisture at the roots until after the fruits are gathered, neither should they be syringed. Later varieties will require another application of water at the roots before they are mulched, and should be syringed on fine mornings only. Important operations are thorough fumigation on calm evenings when the foliage is quite dry and when the earliest fruits show signs of ripening, or syringing with quassia water, always provided the trees are thoroughly washed the next morning and the house well ventilated, with gentle fire-heat to prevent condensation of moisture. Nets should be placed over the ventilator openings to keep out birds, as a constant supply of air is imperative when the fruits are ripening.

Mulching.—This operation is as important in fruit houses as in the open garden. Mulching may not be absolutely necessary immediately, especially upon cold soils, and may, with advantage, be deferred until the sun has made the soil warmer. Much depends on the growth and condition of the roots as to whether stimulants are required; rich manure may not be needed, yet a covering of some kind that will prevent evaporation of moisture and absorb sun-heat may be of the greatest service. Heavy animal manure may be beneficial on light, warm soils, but horse manure, spent Mushroom-bed material or burnt earth and refuse, will be preferable on heavy soils. Established trees carrying heavy crops require stimulants from the time the fruits commence swelling until they are nearly ripe, hence the advantage of covering the borders with some kind of short manure. Fresh stable manure is a very suitable mulch for Vines and stone fruits, as it charges the house with ammonia which acts as a beneficial stimulant to the foliage. Rich organic manure often does more harm than good by making the borders sour and cold, and by encouraging gross, late growth which, in unfavourable seasons, never ripens.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Campanula pyramidalis. — The elegant Chimney Campanula is an excellent plant for furnishing the cool greenhouse and for other decorative purposes. By introducing a few plants into gentle warmth now, and allowing others to remain in the cold frame, plants may be had in bloom over an extended season. When growth is active the roots should be liberally supplied with liquid manure, but no attempt should be made to hasten the plants with fire-heat. Seedlings raised as advised in a previous calendar are now ready for pricking off into boxes. They should be grown under glass until they are well established, and when suitably hardened they may be planted out-of-doors in a well-prepared border and allowed to remain there until the autumn, when they should be lifted and placed in their flowering pots.

Cuttings.—Cuttings of such stove and greenhouse subjects as Dracaenas, Codiaeums (Crotons), Bouvardias and Saintpaulia, are now ready for transferring singly into small pots, care being taken not to break the young roots, which are very brittle. The compost for this potting will depend on the subject under treatment.

Crotons and other stove plants need good fibrous loam and peat, while most of the greenhouse subjects require a mixture of open loam, leaf-mould and old. Mushroom-bed manure, with a liberal quantity of broken charcoal and sand added in both cases. After potting, place the young plants in a suitable temperature to ensure good growth; if a mild hot-bed is available, plunge the young plants of Crotons and Dracaenas in it, and shade them from bright sunshine. Spray them lightly several times each day, but not to such an extent as to cause the top soil to become soured.

Euphorbia fulgens (jacquiniaeflora).—Stock plants of this useful Euphorbia may now be afforded a little more heat to encourage the production of young shoots, which should be secured when about three inches long, as cuttings. These are best taken with a heel of the old wood and, immediately they are severed with a sharp knife from the parent plants, should be placed upright in powdered charcoal to check bleeding. The cuttings should, if possible, be taken in the early morning, before the sun gains too much power, otherwise they are liable to flag before they can be inserted in a sandy compost and placed in the propagating frame. Place three cuttings in a small receptacle, and when rooted, the plants may then be grown on intact or potted up singly. This Euphorbia does best in a stove temperature until the plants are well-established in their flowering pots, when they may be afforded slightly cooler conditions. The roots need careful watering at all times, and they should never be allowed to become excessively dry. Euphorbia pulcherrima requires much the same treatment as advised for the above.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Vacant Ground.—As the winter crops are cleared, all rubbish should be collected from the ground, which should be manured and dug in readiness for other crops.

Beet.—Maincrop sowings may now be made of both Turnip- and long-rooted varieties of Beet, although the former variety may be sown so late as July to provide tender roots in the late autumn, when they are very much appreciated for salad purposes.

Mushrooms.—If plenty of rough material is available, together with a fair quantity of fresh horse manure, another Mushroom bed may be made in the open, in a shady, cool corner. So soon as the bed is ready, it may be spawned, covered with three inches of soil, well beaten down, and then covered over with a layer of hay, which will help to keep it moist. Damp the bed at regular intervals with tepid water.

Peas.—Make further sowings for succession of such tall varieties as Telephone, Telegraph, Edwin Beckett and The V.C., which are good, free-cropping sorts. A mulching between the rows will be beneficial to Pea plants, especially in dry weather, and if any doubt exists as to whether the plants are dry at the roots or not, plenty of water should be given. If Peas are allowed to become very dry at the roots, mildew will quickly set in, and the crop will be spoiled.

Chicory.—A sowing may also be made of Chicory. When the seedlings are large enough, drastic thinning should be done, allowing one foot between each plant, or even more, if good crowns are aimed at.

Gourds.—These may be sown now, placing the seeds singly in three-inch pots; with the smaller varieties three seeds may be sown in a pot. The fruits of the ornamental varieties will, with careful treatment, remain ornamental for many months.

Celery.—The earliest Celery plants for exhibition work will now be ready for planting out in the trenches. Single lines are best for procuring good exhibition sticks. Never allow the plants to suffer through lack of water at the roots; plenty of well decayed manure should have been placed at the bottom of the trench. Should the ground be dry, give the soil a good soaking with water a few hours before planting, and also give the plants a thorough soaking with clear water before transferring them to the trenches.

Runner Beans.—Seeds of these may, with safety, be sown out-of-doors now if the ground has been well prepared beforehand. Dwarf Beans may also be sown.

Turnips.—Further sowings may be made of such Turnips as Dobbie's Model or Sutton's Snowball. Swedes may also be sown, the roots of these keeping well and proving very useful during the winter months.

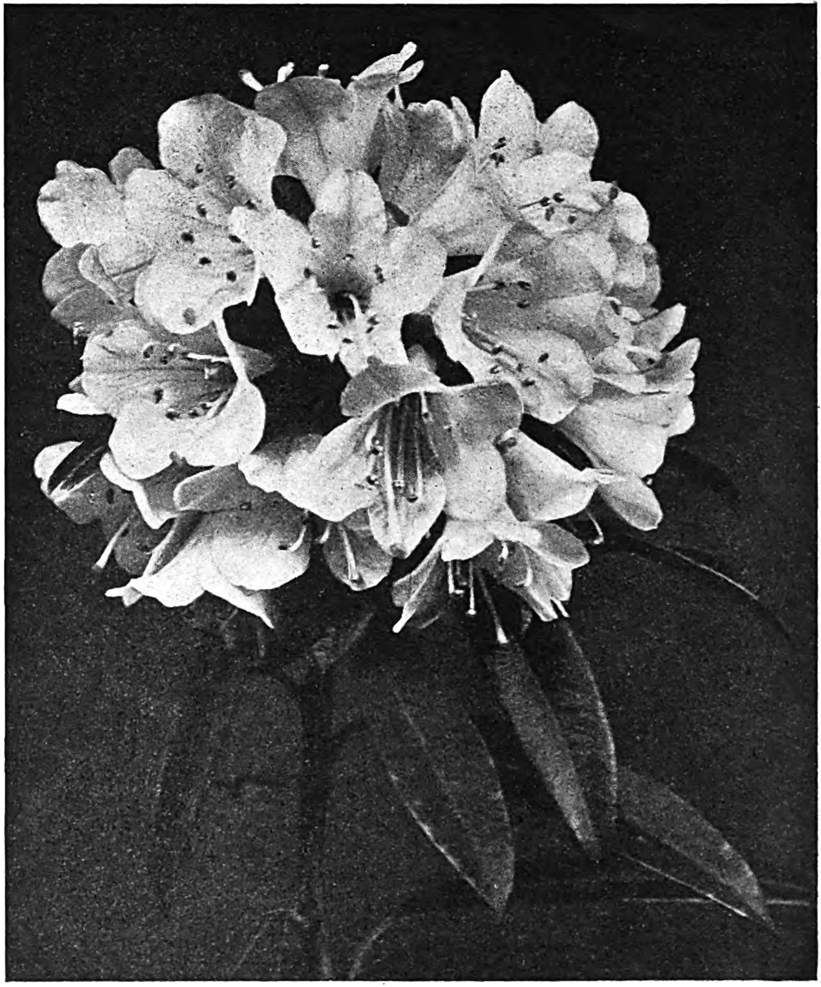

FIG. 171.—RHODODENDRON TEPHROPEPLUM.

R.H.S. Award of Merit at the Rhododendron Show on April 29. Flowers pink. Shown by Lady Aberconway and the Hon. H. D. McLaren (gr. Mr. F. C. Puddle), Bodnant.

(see p. 337.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Plant out Cauliflowers, Cabbages, Brussels Sprouts and Lettuces as they attain suitable size, placing them in deep drills, which will afford protection against wind. The distance apart for planting will be regulated by the habit of each variety, but as a general rule two feet by two feet is suitable; tall-growing Brussels Sprouts require three feet by two-and-a-half feet, while small-growing Cabbages and Cauliflowers require less than the average distance. Brassicas sown out-of-doors in March should now be ready for pricking out, which treatment results in much better plants than if they are left to struggle in the seed-beds. Make frequent sowings of early Turnips and Radishes, as frosts are liable to, and often do, render earlier sowings useless. Thin, hoe between, and stake Peas as necessary, and make successional sowings. Use the Dutch hoe or apply the cultivator among all growing crops at every opportunity, especially where the ground dries after heavy rain.

Bedding Plants.—Get these all hardened off and ready for planting; remove weeds which appear and, in the case of later plants, stir the surface soil frequently. If these plants are growing too strongly a check may be administered with advantage by running a large knife-blade lengthwise and crosswise through the soil between the plants to sever the roots; this will prevent serious root disturbance at planting time.

Chrysanthemums.—September- and October-flowering Chrysanthemums which were planted out recently should now be stopped by pinching out the growing points with the finger and thumb in cases where the natural break has not taken place. As growth recommences, select four of the best breaks and remove the others Promote free and sturdy growth by watering, if necessary, and also by surface cultivation.

Eremuri and Fritillaria imperialis.—These are now starting into growth and should be shaded from the sunshine after night frosts.

Wall Fruit Trees.—Continue to disbud Peach trees and thin the fruits slightly where setting has been free. Afford water at the roots in dry weather and give a dressing of a good fertiliser. If hot, dry weather sets in a good mulch of manure or even short grass will prove beneficial. As Plums, Cherries, Apples and Pears are now in active growth, go over them occasionally, removing unwanted growths near the foot of the tree, so as to assist the fruiting wood. All breast shoots may be stopped at the fifth leaf, especially on cordons. Should mildew appear, spray with lime-sulphur or Medela wash.

FLOWER GARDEN.

MISCANTHUS JAPONICUS.

It is not generally realised how highly ornamental this free-growing, and yet not rampant, perennial grass may be in a garden, for its adaptability and charm are seldom employed to the fullest advantage.

In the first place, it is not very particular as to the soil it is planted in, for it flourishes equally as well either in loam or peat, provided it has been worked deeply and is not shallow. Next, it does not object to a hot, fairly dry position, although it is, perhaps, seen absolutely at its best when enjoying a cool, moist root run; and it flourishes alike in full sun or partial shade. So, it will be seen, M. japonicus is a very adaptable plant, and the above remarks apply also to two highly ornamental, variegated varieties of M. sinensis.

And as to the uses to which it may be put, they are many. It makes a handsome specimen plant for lawns, etc., or it may be grown in large tubs for similar decorative effect. If specimens of it, and of the other mentioned, are dotted about the herbaceous border, the appearance of the latter will be enhanced considerably. It may be grown in groups or as isolated specimens in the open woodland garden, and it is never so attractive as when planted on the margin of a pond or lake.

For M. japonicus is of handsome and stately appearance, and forms a mass, or close sheaf, of narrow, linear leaves, deep green and light and graceful, from three to four feet high, and above these are borne, in the later part of summer, feathery panicles of brownish-purple flowers, quite twelve inches in length, with gracefully drooping branches. As stated previously, there are two grand variegated forms of M. sinensia namely M. s. var. variegata and M. s. var. zebrina. The foliage of the former is striped longitudinally with green and white, so that a well-grown specimen of it is very decorative, while the variety zebrina, as its name suggests, has cross bands of yellow, which contrast brightly with the normal rich green of the foliage. The genus Miscanthus is often referred to Eulalia. *W.*

ALPINE GARDEN.

SAXIFRAGA IRVINGII.

This Kabschia Saxifrage appeals to me for two reasons in particular, although it has other claims. The first is that it is of great beauty, and the second is that it bears the name of one of our best alpinists, who has given much study to the genus Saxifraga and has enlightened us on a good many points of culture and nomenclature. Apropos of this quesiton of nomenclature, I observe that one good authority, at least, states that the parentage of this hybrid is "reputedly between Burseriana and Frederici-Augusti," but Mr. Irving himself tells us that it is a cross between S. Burseriana var. macrantha and S. thessalica.

We have not many hybrids of the Kabschia and Engleri sections with red or pinkish flowers, but S. Irvingii was one of the first, and it has been long enough in many gardens to have proved its worth. It is of very dwarf habit, being only about an inch in height, and has very dense, small cushions of bluish-grey foliage and lovely pink flowers. In the moraine it is quite at home, and it does well in the rock garden. The ordinary treatment afforded the Kabschia Saxifrages will suit it well. It flowers freely here, and, although I grow it in full sun, growers in the sunnier parts of the south may give it slight shade from the strongest sun. It was first sent out as S. Burseriana var. rosea.

ARENARIA BALEARICA.

In the interesting note on the above, on p. 292, your contributor *L. B. C.* states that it "appreciates sunlight." With many, however, A. balearica does not thrive well in places where it receives the direct rays of the sun for any length of time during the day, and always flourishes best in shady, moist positions on and about stones. I have had it on both sides of retaining walls and other arrangements, where on one side the Arenaria received sun for the greater part of the day, while on the other side it only had sun for a short time in the summer evenings. The contrast was remarkable, as the plants on the sunny side were poor and never spread with any degree of rapidity, while those on the shady side throve freely. All were on sandstone. The same may be observed in my present garden, where A. balearica is growing on double stone sandstone walls planted with alpines and flanking two flights of steps. I have seen it flourishing on and about the stones of an outdoor Fernery, and I know a small rock garden where, in shade, it seems to find granite stones quite congenial. The point that it should be planted with discretion so as to prevent it from choking other plants is justly emphasised by your correspondent; weak as A. balearica appears, it is a serious danger to choice plants near it. *S. Arnott.*

RAOULIA AUSTRALIS.

Of very low and close habit, this daintly little Raoulia, from Australia and New Zealand, is valuable for clothing rock surfaces, or for planting in positions practically barren of soil and fully exposed to the sun. For it requires very little soil to sustain it, and when once established will form a wide mat of tiny rosettes of frosted, silvery foliage, all packed closely together and glittering in the summer sun, while even in winter, although naturally not so lustrous, it is still quite effective, and is seemingly oblivious to the vagaries and inclemencies of our climate.

Unfortunately, R. australis has a habit of flowering just when it has attained suitable dimensions to be really effective, and as these small "Everlasting" flowers are devoid of beauty, they impart to the silvery mat a blotched appearance, and leave it patchy and bare in the parts where the flowers were most plentiful, with the result that the lovely carpet is temporarily spoiled, and top-dressing with finely, sifted, light compost has to be applied to encourage it to fill up these bare patches and regain its former beautiful self—a close, ground-hugging mat, rooting as it spreads, of sparkling silver.

If fresh plants are required, division may be resorted to, small portions being pulled from the parent and planted or potted separately, and these will soon establish themselves. *Kent.*

TREES AND SHRUBS.

CYTISUS HIRSUTUS.

This native of southern Europe has been in cultivation for nearly two centuries, but it is not often seen in gardens. It is, however, a shrub well worthy of more extensive use, for its flowers are large, it is always the first of the taller Brooms to give colour here, and it has a certain elegance of character of its own. Being a very variable species, C. hirsutus presents several more or less distinct forms. Mr. W. J. Bean in *Trees and Shrubs Hardy in the British Isles*, describes the type as a somewhat decumbent, deciduous shrub of one foot to two feet in height. In sheltered gardens it will grow taller, but the habit is generally open and the branches few, slender and whippy. The trifoliate leaves are unusually large for a Broom, the oval leaflets being nearly an inch long and half as broad. The undersides of these, as well as the young wood and calyx, are downy. Borne in axillary clusters of two, three or four on the older growths, the first flowers open about mid-April. These are broad and fully an inch in length and of a good, warm yellow, which is intensified by a flare of orange (turning to brown) on the standard. Seeds afford a ready means of increase. The plant is absolutely hardy and the blooms remarkably resistant to spring frosts.

An even more striking shrub is a taller development known as C. h. var. hirsutissimus. This will reach the stature of four or five feet. It is almost erect in habit, and is more downy than the type. Such features are also common to C. ratisbonensis, the only species which is liable to be confused with C. hirsutus. But this tall and stately Broom may, as Mr. Bean points out, be distinguished by the hairs on its twigs, leaves, calyces and seed pods being adpressed. Most of these early-flowering Brooms, and there are others of the class, are sufficiently good as garden shrubs for more general culture. But the average gardener who is not concerned with minute differences will doubtless find two or three of them sufficient. *J.*

PRUNUS PENDULA.

Few trees are more attractive in March and early April than Prunus pendula, commonly called the Rosebud Cherry, a native of Japan, where it grows from fifty to sixty feet high, but is usually under twenty-five feet high in this country. It is a deciduous tree and has a very ornamental appearance with its drooping branches, and is therefore excellent for top-working on standard stocks. It was introduced into this country by Sargent, who described it as a very effective tree with wide, spreading, fountain-like head of branches, and quite common in old temple gardens of Japan.

The leaves of Prunus pendula are from two-and-a-half to three-and-a-half inches long, and more than one-third as wide, lanceolate and long-pointed, sharply, and often doubly-toothed, and glandular near the base, with a stalk three to three-and-a-half inches in length. The flowers are from half- to three-quarters-of-an-inch across, and are pale rose in colour, produced in short-stalked clusters of two to seven, each flower being on a downy stalk half-an-inch or more long, and possessing a hairy calyx. The fruits are small and globose, and are black and shiny when ripe.

Prunus subhirtella, an upright-growing plant of charming appearance, and Prunus pendula are thought to be forms of one species, but Prunus pendula cannot be merely a pendulous sport, as it comes true from seeds. Whatever its origin, it is certainly worth a place in any garden, and the fine specimen in the Botanic Garden, Cambridge, is one of the most attractive trees at the present time. *George H. Preston, Botanic Garden, Cambridge.*

BOG AND WATER GARDEN.

SYMPLOCARPUS FOETIDUS.

Known throughout the eastern United States as the Skunk Cabbage, Symplocarpus fœtidus is the only representative of the genus. It is a most curious plant—a member of the Natural Order Araceae—and derives its vernacular designation from the strong, disagreeable odour which all parts of the plant emit when bruised.

S. foetidus occurs plentifully in swampy locations. The inflorescences appear very early in the year, and occasionally before January 1. The spathes are about six inches in length and are borne close to the ground, usually several in a clump, while the apex is curiously curled in a hood-like manner. Of an apple-green hue, the exterior of the spathe is beautifully mottled with purple and yellowish-green, while the interior is predominently purple.

Within the spathe is the globose or oblong spadix, also purple in colour and entirely covered with flowers spaced about one-third of-an-inch apart, and with their ovaries embedded in the spadix. The flowers are bi-sexual, having a perianth consisting of four hooded sepals, four stamens having two-celled anthers, and a four-sided, pyramidal style. Although the spathes appear so early, the pollen is not usually ripe until late February or March, and in the present year I observed this condition in mid-April. The spathes remain in good condition for a long period, usually well into May, after which they decay, and the large, one-sided heads of berries ripen in autumn.

When, in April, the leaves of the Skunk Cabbage first appear above ground, they are of an attractive light green colour, with paler veins and they somewhat resemble those of the Spinach Beet. They grow rapidly and soon attain a height of two or three feet and are one foot in width; they are ovate, with a cordate base, and are quite glabrous, with the veins strongly marked; the stout petioles are deeply channelled. *T. H. Everett, New York*

ANISOTOME (LIOUSTICUM) LATIFOLIA, HOOK.

THE Auckland and Campbell Islands, which lie far to the south of New Zealand, have a most interesting flora which has scarcely been touched from a horticultural point of view. The plants found on these islands are mostly endemic, although a few are also found in New Zealand and other areas which have sub-antarctic elements in their flora. It is a strange fact that the flora of these islands, which are very cold and windswept, is more colourful than that of New Zealand; for example, all the Gentians found in the main islands of New Zealand are pure white, while those cold sub-antarctic islands are capable of producing a fine purple species.

Anisotome latifolia was first described by Hooker in the *Flora Antarctica* when he founded the genus Anisotome to include the two species, A. latifolia and A. antipoda, which are both found in the same locality. Some twenty years later, he transferred the genus to Ligusticum—*Handbook of the New Zealand Flora*—and there it remained until 1909, when Cheeseman suggested that Ligusticum should be limited to species found only in the northern Hemisphere, and that Anisotome be revived for the reception of species from New Zealand and the outlying islands. This suggestion has since been adopted and that is how the matter stands to-day.

A. latifolia is stated to be fairly abundant in moist places from sea shore to mountain top throughout the groups of islands. It is unquestionably one of the most handsome of the Umbelliferae. In its native habitat it is stated to attain from six to eight feet in height, but in the Dunedin Botanic Garden specimens rarely reach more than three feet in height, despite the fact that they seem to be thoroughly happy (Fig. 172).

A. latifolia is not a common plant in gardens, and because it is a typical Umbellifer, producing a long, tapering tap-root, it rather resents root disturbance. It is a noble plant when growing in the open border. The foliage is of a deep, shining green, and on being bruised, the whole plant exhales a strongly aromatic odour. The leaves, which are some thirty inches long, are thick, coriaceous and bipinnate, with conspicuous reticulate veins.

The dioceous, compound umbels are borne on a stout, erect stem, which is approximately of the thickness of the wrist; at the base it is furnished with broad, concave bracts, which have small, foliaceous tips. The long, compound umbels are quite showy when bearing their burden of numerous, small, purple or rose-coloured flowers.

The closely allied A. antipoda is almost as fine a plant as the preceding, and may be readily identified by its more finely divided leaves with their numerous linear segments. The flowers are stated to be red, but, so far, I have not seen any specimens bearing flowers.

These two plants are semi-evergreen, herbaceous perennials, and are most effective if planted by the edge of the bog garden. They will flourish in the open border provided plenty of moisture is present. They do not seem difficult to please so far as soil is concerned, provided there is plenty of room in which to develop their long, tapering tap-roots. *A. W. Anderson, Botanic Garden, Dunedin, New Zealand.*

HARDY FLOWER BORDER.

HARDY CENTAUREAS.

EXTENSIVE as the genus Centaurea is, there are yet comparatively few members that are worthy of garden cultivation, but among those claiming this distinction are several exceedingly useful and, in some instances, extremely beautiful plants. For practical purposes, these may be divided into three sections. First, there are the half-hardy, silvery-foliaged Centaureas, invaluable for planting in association with flowering plants in summer bedding schemes; next, there are the annual species, which embrace such popular subjects as C. Cyanus (the Blue Cornflower), and C. moschata (Sweet Sultan), both long residents in our gardens, and quite invaluable. And lastly, there are the hardy perennial species, worthy claimants for positions in the flower garden, preferably in the herbaceous border, and it is the purpose of my notes to bring these to the notice of readers.

Most gardeners and plant lovers are familiar with Centaurea montana, the perennial Cornflower or Mountain Bluet, for it has been cultivated in gardens for many years—it was introduced in 1596—and is often to be met with in old-world cottage gardens. It is a very accommodating plant, thriving in most positions and lasting many years, and may be employed effectively in the herbaceous border, the wild garden, or on the margin of the shrub border, in all of which positions it will form a leafy mass, some eighteen inches or so high and more across, and will produce, during early summer, a profusion of rich blue "Cornflowers," with ragged, deeply-cut florets, which may be cut and used for table decoration. C. montana was one of the first plants figured in the *Botanical Magazine* (t. 77), and it may bo had in several colour forms. The variety alba grandiflora has large, pure white flower heads, and is well worth planting, while varieties rosea and rubra, the former pale, and the latter deep rose, are also desirable. C. m. var. sulphurea (var. citrina of some authorities, including Bailey in *Standard Cyclopedia of Horticulture*) is deserving of a place, for its ray florets are pale sulphur-yellow.

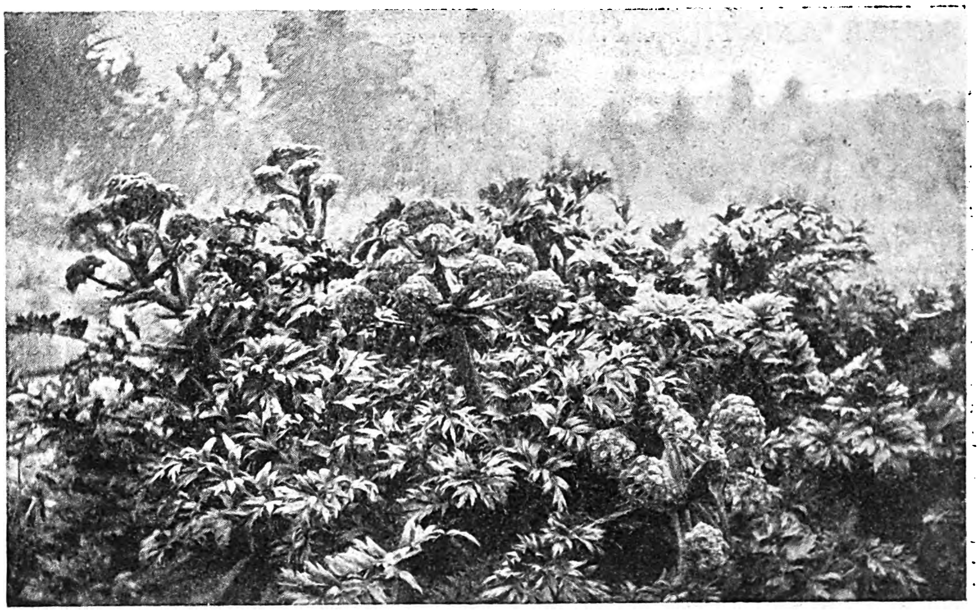

FIG. 172.—ANISOTOME (LIGUSTICUM) LATIFOLIA.

One of the most beautiful of the hardy herbaceous Centaureas is C. dealbata, from the Caucasus. This should be in every herbaceous border, preferably near the front, for it seldom grows to a height of more than two feet, and forms a bushy plant of attractive, pinnate foliage, the slight silveriness of the undersides of the leaves adding considerably to their charm. And then, during summer, the large flower heads, composed of rich rose-pink ray-florets and slightly paler disk-florets, are produced singly, but freely, on semi-erect, leafy stems, and seem to nestle against the dark green, silver-lit foliage to produce a very beautiful effect. C. dealbata is a good perennial, flourishing in deep, well prepared soil; it is quite hardy, having come through last winter unscathed, and may be increased by careful division. With me, this Centaurea does not set seeds, nor, for that matter, do the other species, although I do not know whether this applies to them in other parts of the country—possibly not—as there is nothing in their habit or general appearance to suggest inability in this respect.

More attractive in foliage than blossom is C. babylonica, but it is well worth growing for the former, for its leaves are very handsome, being large and clothed with bright, silvery-white, cottony down. It may be grown in the herbaceous border, or afforded a bed to itself, in a sunny position, and, to be truly effective, it should be grown in deep, light loam. If it is allowed to flower it will send up a stout, erect stem to a height of close on ten feet, leafy below, and furnished on the upper portion from July onwards with almost sessile, yellow flower heads, each produced in the axil of a narrow, leaf-like bract. C. babylonica would not appear to be long lived, but seeds, and plants, are often offered, and so stocks of it may be obtained. It is a native of Asia Minor, and has been in cultivation many years.

Another handsome species, and a strong-growing herbaceous perennial, is C. glastifolia, from central Europe, and described in *Bot. Mag.*, t. 62, even before the better-known C. montana. It is of striking appearance, for it produces stout, branching, winged stalks four feet or so high, and these bear large, solitary flower heads of rich golden-yellow, which are very effective when cut and used for room decoration. Provided it receives generous treatment, C. glastifolia well repays inclusion.

One of the most popular of this group, and not uncommon, is C. macrocephala, the Great Golden Knapweed, a native of Armenia, and figured in the *Bot. Mag.*, t. 1248. It is strong and vigorous-growing, producing simple, erect, leafy and hollow stems to a height of about four feet, for which reason it should be planted well back in the herbaceous border, in deep, rich soil. And these growths, during July and August, are crowned with huge, solitary flower heads, quite the size of hen's eggs, and composed of closely-packed florets of bright golden-yellow; as if to provide the extra strength needed to carry these giant inflorescences, the flower stems are swollen just beneath them.

Although rather coarse-growing and amply foliaged, these traits should not deter its inclusion in the herbaceous border of large dimensions, albeit it may hardly be suitable for a place in small collections of really choice plants.

Lastly, there is the handsome C. ruthenica, from the Orient and central Europe, a species with attractive, pinnate foliage. It is free-flowering, producing a succession of blooms from July to September. These are borne on erect, branching stems, rising above a mass of leafage to a height of three feet, the large, loose flower heads consisting of pale, strawy-yellow florets. Like the other species, C. ruthenica is a good perennial and repays generous treatment—deep, cool, well enriched soil, with, perhaps, slight shade from the hottest sun, although this latter is not essential. *M. W.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

CHILE AND THE ANDES.*

No. XI.

WE had been promised an introduction to the "King of Coquimbo," but although this introduction did not materialise, we nevertheless called upon him the day after our arrival, and received a most cordial welcome. He at once suggested that he and his family, and we with them, should migrate forthwith to his country seat, a charming farm at the foot of a range of mountains five or six miles out of town. Never was such a delightful, impetuous host. He lunched us and then motored us all out, two car loads of us, for a picnic tea at the farm. It was a typical Chilian farm (Fig. 173), a big, square, spacious house, two-storied, with lofty rooms, and a wide balcony running all round it. In front was a courtyard with Palms and flower beds, Violets, Wistarias, Roses, Freesias, and a pool with fish. Here we were received by an Irish wolfhound, a gigantic creature of surpassing dignity, and with a voice like the deep rumbling of an earthquake. After tea, we walked out in the direction of the mountains, which were of no great height, and were only a mile or so away, and at once we realised that Leucocoryne had lured us to a first-class paradise. The ground between the farm and the mountains was stony, sandy loam, undulating, and carrying a thin scrub of low bushes, Oxalis gigantea, Solanum pinnatum, and a delightful Heliotrope (C. E. 36, possibly Heliotropium pycnophyllum), with the foliage and habit of an erect Rosemary, three feet high, and with spreading heads of very fragrant, white blossoms. Upon this land, within two or three hundred yards of the farm, we came upon Leucocoryne ixioides (odorata), "Glory of the Sun." Never have I seen such an astounding flower picture. It grew in misty sweeps by the mile and by the million, springing leafless from bare, barren ground, the wiry, graceful stems carrying umbels of from three to five, six, or even seven, blue flowers, white-centred and shaped like Chionodoxa, but much larger. They varied a good deal, some paler, some darker, some one-and-a-half inch and others a full two inches across, and they had a powerful, delicious, Almond fragrance, which comes near to, but is not quite, the scent of Heliotrope. For an hour or so we just wandered about among these fields of Leucocoryne, too astonished and enchanted to take a single blossom or dig a single bulb. Ours was the colossal fortune to have happened on this incomparable plant, and to have been invited to come and stay as long as we would at the farm, convenient at its very door. For that blissful afternoon we luxuriously basked in a delicious mixture of Chilian spring sunshine, the thrill of a great find, a scene of extraordinary beauty, and a feeling that this find alone made our two hundred mile journey north more than well worth while. It justified the whole journey to Chile.

On this same tract of country grew another blue-flowered plant, more brilliant than Leucocoryne, if not more beautiful, a Convolvulaceous plant, Nolana littoralis (C.E.4). It had a little, Carrot-like, perennial root, from which radiated trailing stems, thickly studded with big, cup-shaped blossoms, two or three inches across, of a brilliant, clear Nemophila-blue, white-centred, and with yellow at the heart. Each plant was a foot or eighteen inches across, and they grew in vast colonies of many thousands at a time. The plant has rather the appearance of Convolvulus minor, absolutely prostrate, but more refined and brilliant and beautiful. I felt sure, however, that somehow it would never make so good a garden plant as Leucocoryne. Almost certainly it would not prove hardy, and its prostrate habit was against it as a greenhouse plant. As a half-hardy annual, however, it may turn out a treasure.

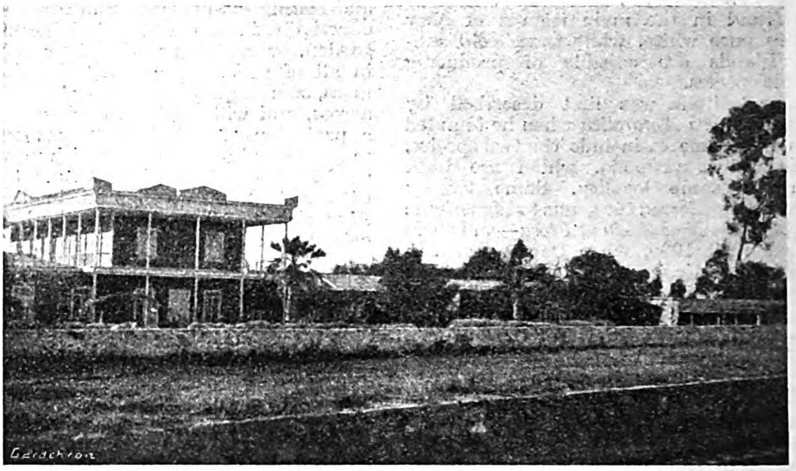

FIG. 173.—THE "KING'S" FARM HOUSE, COQUIMBO.

Leucocoryne, on the other hand, would, I felt, make a first-rate greenhouse plant, an opinion which it has since done much to confirm. And here I will go ahead of my narrative and tell of the doings of Leucocoryne since I sent it home and how it has fared in captivity. The bulb is about the size of a Snowdrop, and is very difficult to get up out of its hard, sandy, stony soil. But I secured a great store of them in the end, and ripened them off on the sunny balcony of the farm, and then I packed them, very, very carefully, in two great crates, with special precautions for ventilation and against rats, and I shipped them off to England, with special instructions as to storage. Then weeks and months after they should have arrived, came news of their non-arrival, awful waits, maddening silences, and frantic cablings, and finally a cable from home "Bulbs arrived in sound condition." Having found the plant flowering in September, I thought it would probably flower here at about the same time. Not a bit of it. I planted mine out in a bed in an airy greenhouse about mid-summer, and nothing happened. I gave them gentle heat, a temperature round about 50°, and at last, in November, they began to push out leaves—long, narrow and sprawling, but not a sign of a flower bud, and I began to fear that as collected bulbs they were not going to flower. It was not until the middle or end of January that one or two buds began to push up. In February I heard that Mr. Lionel de Rothschild's plants were going to flower, and in February and March Mr. Bedford brought flowers from Exbury to the R.H.S. shows. One lovely picking of a dozen or so heads on February 26 was just not quite fresh enough, Mr. Bedford thought, to put before the Floral Committee, but their fragrance and grace were all there, and they made a decidedly good impression on all who saw them. To me they recalled vivid memories of sun-drenched hillsides at Coquimbo. Mr. Bedford grows his Leucocorynes in a house with Freesias, and gives them the same treatment. Here my first flower opened on March 13, rather a deep-coloured type, one-and-a-half inch in diameter, and one of a head of three. I gathered it with another head of two unexpanded buds, and brought them into a living room to find out how the buds would open in water, and how the flowers would last. Six days later all the buds had fully expanded and were entirely satisfactory as to substance, colour and scent. An important point this, from the cut flower point of view. The second spike had flowers exactly two-and-a-half inches in diameter. At the time of writing, they had been in water for eight days and were still as good as ever. *Clarence Elliott.*

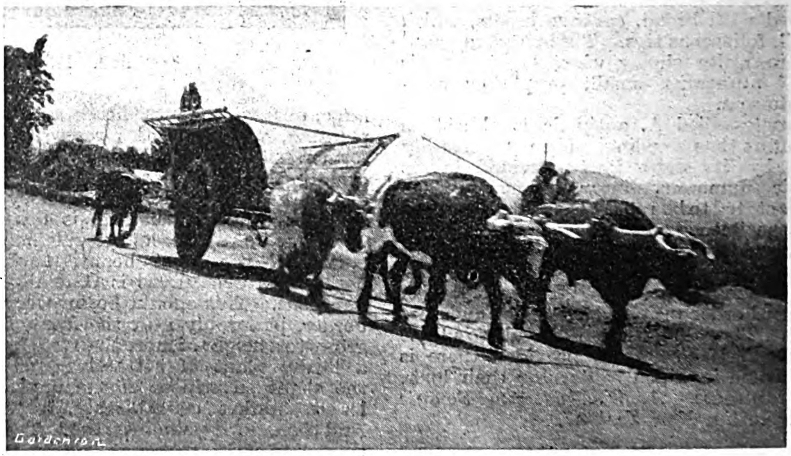

FIG. 174.—A CHILIAN FARM CART.

---

* Previous articles on Mr. Clarence Elliott's expedition were published in our issues of November 12 and 26, December 10 and 24, Vol. LXXXII; January 7 and 28, Vol. LXXXIII; July 28, Vol. LXXXIV; March 23, April 6 and 20, Vol. LXXXV.

PLANTS NEW OR NOTEWORTHY.

JACARANDA ATROLILACINA, N. SP.

ONE of the commonest flowering trees in cultivation in the sub-tropical and warmer parts of Australia is Jacaranda acutifolia, H. Bonpl. (J. ovalifolia, R. Br.; J. mimosaefolia, D. Don.). About Brisbane, this tree makes a wonderful showing in the spring months with its large panicles of flowers, mostly of a pale lavender colour.

In going through one of the Brisbane parks a short time ago, I saw two trees of another species of Jacaranda I thought might be Jacaranda tomentosa, R. Br., but as they did not quite agree with Bureau and Schumann's description of that species as outlined in the *Flora Brasiliensis*, I sent specimens to the Royal Botanic Gardens, Kew, for examination, where they were reported on by Mr. V. S. Summerhayes, as follows :—

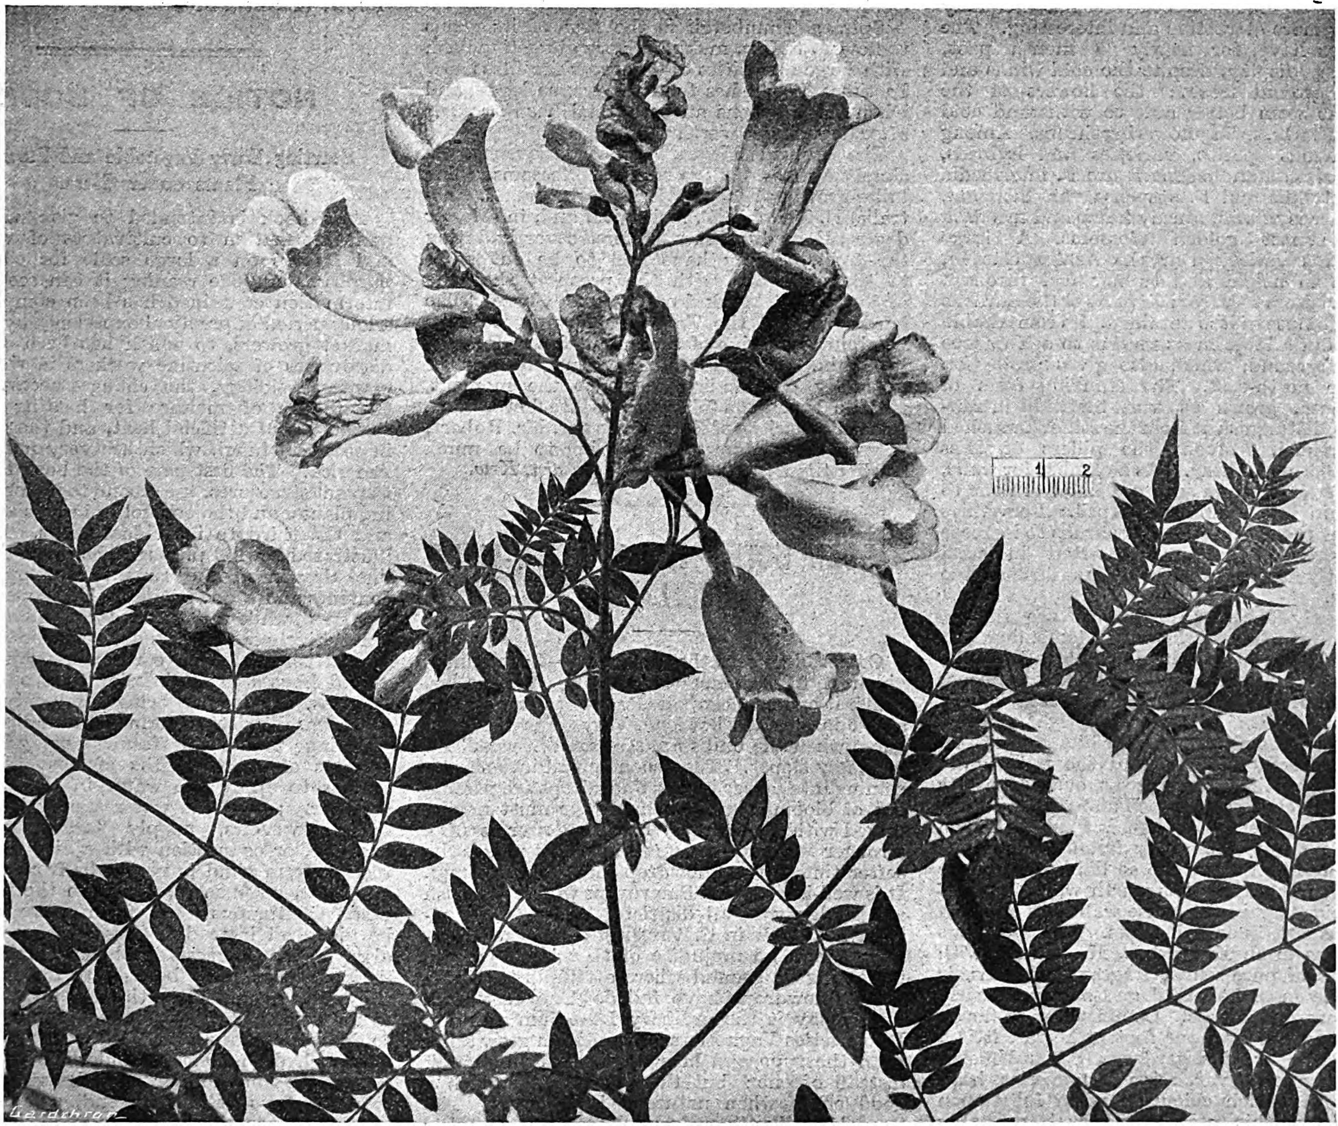

FIG. 175.—JACARANDA ATROLILACINA.

"The plant sent as Jacaranda tomentosa, R.Br., agrees with that species in its indumentum, a character with regard to which J. tomentosa occupies an isolated position in the genus. Mr. White's specimen differs in having a truncate calyx with sharp teeth, while J. tomentosa has blunt calyx lobes. In addition, the leaves are more compound in the Queensland specimen and the leaflets are more sharply pointed. It is possible that the specimen is a hybrid between J. tomentosa and J. acutifolia, H. Bonpl., but, on the other hand, it may be an undescribed species. It agrees with no other species of Jacaranda in our collections."

Nothing is actually known about the origin of the two trees, one of which stands on either side of the main entrance gates of the New Farm Park. Mr. H. Moore, City Parks Superintendent, tells me they were planted out as young trees from the town nursery of the Queensland Acclimatisation Society soon after it was taken over by the Brisbane City Council. Mr. E. W. Bick, Curator of the Brisbane Botanic Gardens, and at one time propagator to the Queensland Acclimatisation Society, tells me he thinks the seeds were sown as J. heterophylla, but I cannot trace this name in literature.

I have now decided to describe the tree, naming it in reference to its dark lilac flowers. Some readers of *The Gardeners' Chronicle* may recognise the tree either in the wild or in garden culture, and if so, I would like them to write to this effect.

Jacaranda atrolilacina, C. T. White, n.sp.* (Fig. 175) is a small tree about 6 m. high, with a rather spreading crown; young branchlets, teeth. leaves and inflorescences clothed with a soft, velvety pubescence; branchlets four-angled, but the angles rounded, flattened at the nodes. Leaves impari-bipinnate, up to 30 cm. long and 15 cm. broad, mostly with eight pairs of pinnae; lowest pinnae 4 cm. long and 5–7 foliolate, middle pinnae up to 12 cm. long and 21 foliolate; the uppermost pinnae smaller, but up to 17 foliolate; lateral pinnules 1·5–2 cm. long and about 7 mm. broad, ovate-lanceolate or broadly lanceolate, oblique at the base, acute at the apex; terminal ones mostly longer and narrower and drawn out towards the apex into a long, acute point up to 3 cm. long. Inflorescence a terminal panicle of 15–20 cm. diameter, branches and pedicels slender. Calyx 4 mm. long, velvety pubescent outside, with five acute Corolla deep lilac; the inside of the tube has a broad, white band along its length on the lower side; velvety pubescent outside and with a few rather long, scattered hairs here and there inside; tube 4 cm. long, lobes about 1 cm. long, and the same across. Stamens four, fertile; filaments thickened and papillose-hairy in the lower part, curved and glabrous in the upper part, the two longer ones 2 cm., the two shorter ones 1·5 cm. in length; anther cells divaricate, about 3 mm. long; staminode 3·5 cm. long, papillose-pubescent in the upper two-thirds. Pistil glabrous, disk 2 mm. high, ovary 2 mm. and style about 3 cm. long. Capsule not known.

---

* *Jacaranda atrolilacina, C. T. White, n. sp.*—Abor ca. 6 m. alta, ramulis novellis foliis inflorescentiisque velutino-pubescentibus, ramulis novellis subangularibus ad nodos complanatis. Folia impari-bipinnata ad 30 cm. longa et 15 cm. lata plerumque 8-jugata, pinnis infimis 4 cm. longis et 5-7 foliolatis, pinnis intermediis ad 12 cm. longis et 21 foliolatis, pinnis supremis minoribus sed ad 17-foliolatis; pinnulis lateralibus 1·5-2 cm. longis ca. 7 mm. latis, lanceolatis vel ovato-lanceolatis ad basin obliquis ad apicem acutis, pinnulis terminalibus plerumque angustioribus et longioribus apicem versus angustatis ad 3 cm. longis. Inflorescentia 15-20 cm. diam. ramulis et pedicellis gracilis. Calyx 4 mm. longus extus velutinus, truncatus, dentibus 5, acutis. Corolla atro-lilacina extus velutino-pubescens intus pilis paucis obsita, tubo 4 cm. longo, lobis ca. 1 cm. diam. Stamina fertilia 4, filamentis basin versus incrassatis et papillosis, 2 longioribus ca. 2 cm. et 2 brevioribus ca. 1·5 cm. longis, antherarum loculis divaricatis angustis ca. 3 mm. longis, staminodio 3·5 cm. longo in parte superiore papilloso. Pistillum glabrum, disco 2 mm. alto, ovario 2 mm. et stylo abt. 3 cm. longo. Capsula ignota.

Described from cultivated tree, New Farm Park, Brisbane. C. T. White, No. 3,265, 19-10-1926; No. 5,595, 7-3-1929. *C. T. White, Government Botanist, Brisbane, Queensland, Australia.*

NOTES FROM KEW.

Notwithstanding the unfavourable, cold weather and lack of rain, trees and shrubs in the pleasure grounds and arboretum, are daily becoming more attractive and interesting. The Forsythias have, for nearly a month past, made a gay display, despite the cold winds and morning ground frosts; the flowers of the Forsythias seem better able to withstand cold than most early, spring-flowering shrubs. Among the numerous species, varieties and hybrids, the two of outstanding merit are F. intermedia var. spectabilis and F. suspensa var. Sieboldii. The former is of stiff, sturdy habit and has dark yellow, almost golden blossoms. A large bed of this variety near the Azalea Garden, nine feet in height and twenty feet through, attracts visitors to it from all parts of the Gardens where a glimpse of it is obtained. Its remarkable beauty is in a large measure due to a Yew tree as a background, which also gives protection from the north-east. The climbing form of F. suspensa, grown as var. Sieboldii in nurseries, to distinguish it from the stiffer-branched var. Fortunei, festoons the pillars of Miss North's Picture Gallery. As a climber for walls, fences, verandahs and arches, I know of none to equal it in late March and April. Forsythias are among the easiest of hardy shrubs to increase by soft-wooded cuttings, inserted in sand in a slightly heated propagating case during June and July.

The early-flowering Magnolias are nearly, if not quite, a month later in blossoming this year. The first to open its flowers was Magnolia salicifolia, very closely followed by M. conspicua, M. stellata and M. Kobus. M. salicifolia is very distinct in habit; of slender, upright growth, it is almost Lombardy Poplar-like in outline. It is a native of Japan, and the pure white blossoms are followed by narrow, oval-lanceolate leaves. M. conspicua, the Yulan or Lily Tree, which has pure white flowers, is the best known of all the Magnolias. Very free-flowering, the white, Lily-like flowers are so liable to damage by spring frosts that it is worth while to plant M. conspicua against a house wall with a south or west aspect, in cold districts. For lawn beds and groups in shrub borders, M. stellata, with its masses of pure white, fragrant blossoms, is one of the most beautiful and showy of early spring-flowering shrubs. Commencing to flower when not more than one foot in height, it is a useful shrub for villa gardens. Several bushes of the pink form, var. rosea of nurseries, have retained their rich colouring when fully open much longer this year than usual, probably because of the cool weather. M. Kobus is flowering freely on a wall; its robust, tree-like character is shown by the growth of the branches far above the limited height of the wall. The specimen in question has attractive, white flowers and is one of the good forms of M. Kobus, which varies considerably when raised from seeds.

The Flowering Currants, varieties of Ribes sanguineum, are attractive subjects for shrubbery borders during April. In addition to the species, which has showy, rosy-red blossoms, there is var. splendens, with glowing red, pendent blossoms; and var. atrorubens, deeper still in colour but with not quite such large racemes of flowers, nor so free in growth as the type. If only one form had to be grown, most flower lovers would choose the variety King Edward VII, an attractive bush with bright, dark red blossoms. When space permits, the variety album, white, and variety carneum, pink, are deserving of attention to give variety of colour.

The Buffalo Currant of the Central United States, Ribes aureum, is very distinct and beautiful among April-flowering shrubs. The golden-yellow blossoms are borne freely along the branches, and they have a pleasing fragrance. R. Gordonianum, a hybrid between R. sanguineum and R. aureum, is a desirable, free-flowering shrub of robust habit, with rosy-red flowers, shaded with yellow inside.

A large bed of the double-flowered Peach, Prunus Persica var. carneo pleno (Clara Meyer of nurseries) is attracting hosts of admirers. The specimens are producing their rich rose-coloured blooms with unusual freedom, perhaps because the frosts delayed the development of the flower buds. They have certainly escaped damage by bullfinches this year. Elsewhere, the white variety albo pleno, var. sanguineo pleno, and var. magnifica, crimson, are flowering freely.

Spiraea Thunbergii is the first of its genus to flower at Kew, making a very attractive bush with large quantities of dainty, white blossoms. In time, the bushes tend to become leggy, and when this happens an occasional hard pruning after flowering is worth while.

The hybrid Heath, Erica darleyensis, is simply a mass of deep rosy-red blossoms. The taller-growing Heaths, Erica arborea, E. australis, E. Veitchii, E. lusitanica, and, in a lesser degree, E. mediterranea, suffered severely during the frosts. Many have had to be cut back to the old wood with the prospect that the majority will break from near the base. The hardiest of all the Tree Heaths proves to be E. alpina, a native of the mountains of Cuenca, in Spain. This is quite undamaged, and of distinctly outstanding merit at the moment, with its dark green foliage and white flower buds. The white variety of E. australis var. Mr. Robert, is very little damaged, proving to be much hardier than the species. *A. Osborn, Kew.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

One seldom sees the Snowflake—Leucojum—given a fair chance of showing its quality, which it cannot do when clumps of it are dotted about in a mixed border. Very different is the effect when the bulbs are scattered in woodland or grassy slopes. They soon spread into sheets, coming into flower just as Snowdrops are passing out of bloom; but the Snowflake must not be mixed with Snowdrops, for its flower is of a stronger and more opaque white that makes the softer tint of the Snowdrop look almost dingy. It is well-known that Snowdrops will not flourish and multiply in all districts. They are somewhat fastidious in that respect; but the Snowflake shows no prejudice of that kind, rapidly increasing in ground where attempts to naturalise Snowdrops have failed. The best form for display is the ordinary Leucojum vernum. Its varieties Vagneri and carpaticum grow taller than the type and bear two heads on a stalk instead of one; but they do not give such a good effect when naturalised in sheets. The Snowflake, like Snowdrops, Narcissus and other members of the Amaryllis family, enjoy complete immunity from rabbits.

The colours of spring flowers are so strong that it is well to note accidents of harmony and contrast with a view to re-arrangement. A pleasing group that commands approval at present is formed by a self-sown scattering of Narcissus bulbocodium var. citrinus, among which the scarlet Tulipa praestans and Muscari conicum var. Heavenly Blue show to much advantage. Another pleasing combination has come by chance from Aubrietia deltoidea var. graeca spreading a lavender carpet under Narcissus Queen of Spain.

On the other hand, a heavy job awaits transaction in autumn in the transplanting of three large bushes of Rhododendron praecox beside which R. neriiflorum has risen to a height of five feet, its scarlet trumpets jarring painfully with the rosy cloud of the others.

We are learning more as the season advance about losses sustained during the past winter. The Chilian Ercilla volubilis, more commonly known as Bridgesia spicata, having grown in twenty years to the height of eighteen feet on a south wall, has been killed outright. The loss does not afflict one, for it is not a plant of decorative merit; and close to it Berberidopsis corallina has not suffered at all. On the same wall, Abelia floribunda, which has never flinched during many previous winters, is badly disfigured, while Calceolaria violacea along the foot of the wall has been cut back to the roots. On other walls, large plants of Abutilon megapotamicum are defunct, only one surviving through shelter of overhanging eaves. All this damage is attributable, not to unusually low temperatures—we never had more in the air than 12° of frost—but to the furious winds of February, which intensified the effect of the cold. *Herbert Maxwell, Monreith.*

NOTICE OF BOOK.

Starting Early Vegetable and Flowering Plants under Glass.*

This book is intended to give suggestions and information to cultivators of vegetables and flowers on a large scale for commercial purposes. Anyone reading it can see that the information contained has been compiled from a long period of practical experience by ordinary market growers, to which has been added the discoveries of scientific workers in the field of plant physiology, the changes necessary from the failure of manure for heating purposes to the use of artificial heat, and the control of insects and fungi, which are very numerous in America. The first part of the book is devoted to plant structures, the second to factors in growing plants, and the control of insects and fungi, and the third to individual crops. It is well illustrated by 153 photographs, including a few line drawings, and runs to 302 pages, with contents and a good index. The paper is heavy and good, while the type is large and readable.

Relatively steep roofs are considered superior to flattish roofs for early work, and double glazed houses much inferior to a single layer of glass, the former being used only in cold, northern districts. Permanent equipment for watering plants in frames or greenhouses consists of short lengths of hose fitted with nozzles to apply the water in the form of a fine spray; and the water supply is available from reservoirs, supply tanks, pneumatic pressure, or connection with a city main. Protection from wind is necessary from the north and west, whereas we say from the north and east. Continuous cold frames are made to be ploughed instead of dug, because labour is always the biggest problem. Hot-beds of various types have been used for more than thirty-five years. For these frames, the hot-water type of heating is more expensive and not so durable as flues of vitrified tile. One form of heating had an air space under the beds, where the smoke and hot air moved slowly towards two chimneys at the far end, so that if one became inoperative owing to wind, it could be closed. Heating with manure and electricity show no decided advance, so far as plant growth is concerned.

Sash greenhouses are now taking the place of hot-beds because they are more economical in the matter of heating, suitable moisture and ventilation. Lean-to houses and two-thirds span must always face to south, but in even-span houses, the author considers they may run north and south, or east and west. Sunk houses are easier to keep warm than those above ground, but this depends on the water-level in the soil, because the stokeholds would get filled with water, drowning out the fires, if the water level were near the surface. Growers aver that they can get stockier plants grown upon solid than on raised benches, with less watering. Hot water and vapour systems of heating are preferred to steam heating because a more even temperature can be maintained, whereas the steam cools so quickly that night attention may be necessary. The boiler should be one size larger than is actually necessary, as it requires less attention. Tile, flue-heated houses are very satisfactory where wood fuel is abundant. The wood must be kept smouldering to avoid excessive heat, and the furnace requires feeding only three times a day.

---

* *Starting Early Vegetable and Flowering Plants Under Glass.* By Charles H. Nissley, Extension Specialist in Vegetable Growing at the New Jersey State Agricultural College. Illustrated. New York: Orange Judd Publishing Company, Inc. London: Kegan Paul, Trench, Trubner and Co., Ltd. Price $3.

The acreage of transplanted crops in the United States, such as Cabbages, Cauliflowers, Tomatos, and other commercial truck crops, is 1,397,360. Large and heavy Sweet Pea seeds give earlier blossoming, and more and larger flowers, and this also applies to Pumpkins, Lettuces, Spinach, Parsley, etc. The author suggests screening the seeds, but that seems to be the seedsman's business. A common custom is to sow more seeds than are really wanted, and to pick out the strongest plants, just as is done in Britain. With reference to the longevity of seeds, he states that absence of moisture and an even temperature in the storage house is the controlling factor in seed life. In a state of nature seeds in the soil may be moist enough over a long period of years, but here the controlling factor may be the absence of sufficient air. Well-matured seeds in store keep longest.

Soils for the making of composts, including manure and turf, are prepared one year previous to use, or even two. To avoid diseases, which are numerous in the United States, it is recommended to move the frames, or soil, or sterilise it. Sterilisation by steam is considered the best method, and by formaldehyde the second best. Rubbish is sometimes burned on frame beds to sterilise the soil. Clay pots are reckoned the best for all purposes, where plants have to be established to enable them to transplant easily, but several other plans are adopted in some places. Experiments were made in the hardening of plants to discover what really took place. Tomatos showed a greater transpiration with a rapid replacement of roots, so that accumulated foods were used in root growth. Cabbages showed a slowing of growth, more bloom on the leaves, which were thicker than non-hardened leaves, with a greater resistance to cold.

In the control of insects, it is stated that the alcoholic extract of Pyrethrum flowers in a solution of soap, is more powerful than nicotine, and when used as a spray, will kill all insects in the course of a few minutes up to twenty-four hours. Many names are given to preparations of Pyrethrum powder in America; and evidently some of the non-poisonous insecticides in this country are of a similar composition.

Readers of the book in this country will find a curious use of some words, such as sash and tile in the plural sense, as we use sheep, deer, fish, etc. Other cases are dehis for dehisce, adsorption for absorption, etc. In such words as labor, vapor, etc., the Americans have adopted the pure Latin instead of the Norman French spelling used in this country. All the same, the instructions given in the book could be put to much practical use by market gardeners and growers on a large scale in Britain.

BULB GARDEN.

NARCISSUS RUPICOLA, DUF.

Although figured in the *Bot. Mag.*, t. 6,473, in 1880, this charming little species does not appear to be as common as one might expect. It is very closely allied to N. juncifolius, in fact coming from the same region of the Sierra de Guaderrama. On the average, N. juncifolius flowers a little sooner, while the most striking difference is the sessile or stalkless flowers and the boat-shaped ovary of N. rupicola as compared with the round ovary and stalked flowers of the former; otherwise the appearance of both, when in flower, is very similar.

The rich yellow flowers are borne on stems three to five inches long, stiffly erect and slender. The boat-shaped ovary, some half-an-inch in length by an eighth-of-an-inch in breadth, nestles at the base of a beautiful spathe three-quarters-of-an-inch in length. The perianth tube is three-quarters to an inch-and-a-quarter in length by an eighth-of-an-inch in breadth, and strikingly slender when compared with the corona, the latter being a quarter-of-an-inch in breadth and three-sixteenths to a quarter-of-an-inch in depth, of the same colour as the petals, strikingly mucronate and slightly reflexed. The anthers, six in number, are sessile; the style also is shorter than the perianth tube.

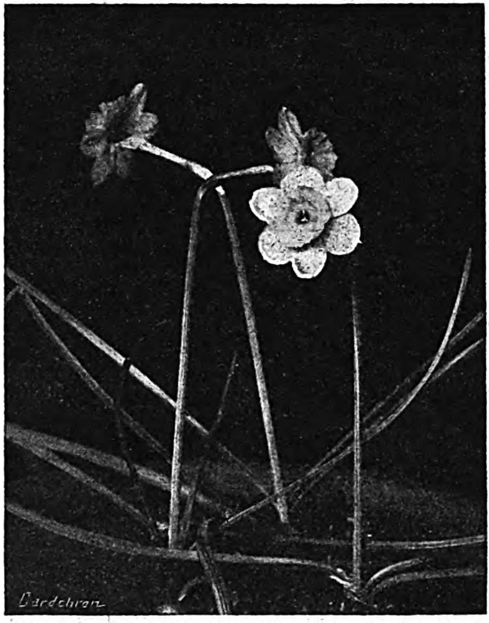

FIG. 176.—NARCISSUS RUPICOLA.
Broad-petalled and spreading-leafed form.

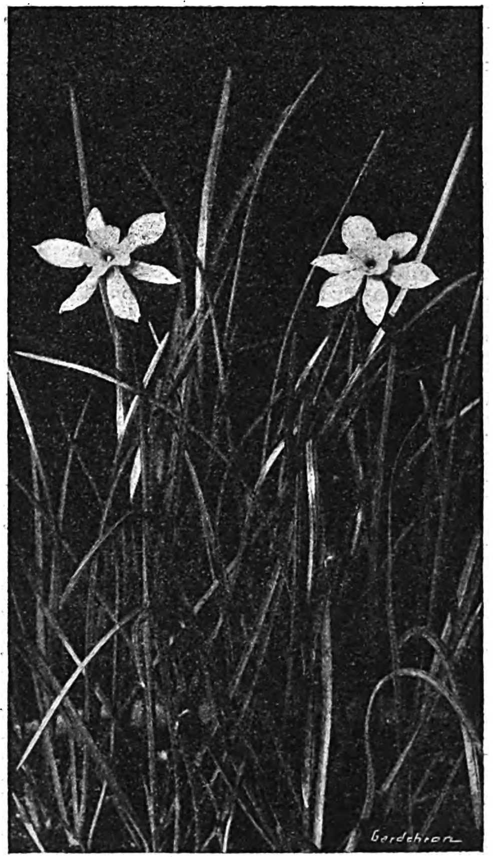

FIG. 177.—NARCISSUS RUPICOLA.
Narrow-petalled and erect-leafed form.

The leaves, arising from a small, ovoid bulb half-an-inch to three-quarters-of-an-inch in diameter, with a cylindrical sheath produced to an inch above the neck, are glabrescent, three to eight inches in length and up to an eighth-of-an-inch in breadth, with a distinct groove running down the centre of each.

The species appears to be variable, for in some instances the leaves are many and stiffly erect, while others are almost horizontal, with a slight upward tilt at the apex and much more glabrescent. In the erect-leafed type (Fig. 177) the petals are long and narrow, and the flowers carried on long, slender stems; in the spreading form (Fig. 176) the petals are almost round, being much shorter and less reflexed than in the former. The coronas do not appear to possess such a marked difference, as in all types they may be sharply cut into three or more lobes, or may be merely frilled.

The bulbs are perfectly hardy, having withstood the past severe winter outside in pans, although some of the forms would appear to be shy flowerers, while others, mainly the broader-petalled types, have all borne flowers. N. rupicola should be an excellent species for planting in well-drained, not over-exposed, positions in the rock garden. *A. Edwards, Kew.*

HOME CORRESPONDENCE.

Manuring Arable Land.—In answer to *C. de B.* re the above (p. 314) it is quite possible to plough in twenty to twenty-four tons of manure to the acre. Like *C. de B.*, I was bred and brought up on a farm, and turned to horticulture, but retain a keen interest in all appertaining to the farm. The manure should be fairly rotten and not too long, and it must be spread evenly over the ground. When we used four horses in a swing plough (what they used to call a digger—the slide share being more in the nature of prongs), from the coulter to the furrow we had a stout, short chain with a weight at the end; this drew all the manure and stubble into the furrow. With four good horses and a swing plough (one without wheels) one may go to a good depth and cover all the manure in. I have had no experience of farm tractors, so cannot speak for or against them. *T. B. Rawdon.*

The Colours of Flowers.—If anything was needed to prove the need of a colour-table for horticulturists, like those adopted in France and Germany, it is given by the recent statements made by the writer of some notes on blue-flowering plants. We are informed that "the first blue effects of the year are obtained from some of the Crocuses," among other spring-flowering bulbs which he names. Violas and "blue" Aubrietias are also included. We are also informed that Scabiosas, Michaelmas Daisies and some of the Geraniums contribute their share of blue to the borders, while "amongst climbing plants, blue is a predominant colour of the larger Clematises"! To those who regard the word blue as having a definite colour-value it is distressing to have it used in this misleading, indefinite way merely as a "generic" term. In the colour-scale we have mauve and purple all getting colder in tone until we reach the blue and cold spectrum-violet at the limit of our visional response. It is very trying that horticulturists have to tolerate the statements of those who persist in confusing these colours, while in the world of music a man is not allowed to persist in playing or singing C flat, C natural, or C sharp for D. Here, if we have any doubt, we have a tuning-fork to guide us, and so we want a colour-table or some definite guide to prevent distressing colour discords reaching our eyes. Sounding two semi-tones together is not more distressing to the ears than seeing Aubrietia and Myosotis placed together and hearing that Crocuses and Clematises provide blue colour. The writer of the note referred to does not even mention Plumbago capensis, the Gentian, Chicory, the Hyacinth, Cineraria, Ceanothus, the Cornflower, and a host of true blue plants available. *A Distressed Horticulturist.*

Antiseptic and Cooling Properties of Volatile Essential Oils.—I was interested in reading in your pages a few weeks ago (p. 192), the report of a lecture, in which the antiseptic powers of the vapours of volatile vegetable oils was referred to. Professor Chamberlain made experiments which proved this. Culture tubes containing bacilli were treated with various essential oils and were opened six days afterwards, when living cultures appeared in some of the tubes, but not in all of them. Thus it was inferred that in some, the essential oils had destroyed the vitality of the bacilli. Those which proved most effective were Cinnamon, Angelica, Geranium and Origanum. The following essential oils killed the germs of typhoid in the times stated below :—

Cinnamon of Ceylon ...	in 12 minutes.
Cloves	in 25 „
Eugenol	in 30 „
Thyme	in 35 „
Wild British Thyme ...	in 45 „
Verbena (India)	in 45 „
Geranium (France) ...	in 50 „
Origanum	in 75 „
Patchouli	in 80 „
Absinthe	in 4 hours.
Sandal Wood	in 12 „

The essential oils of Lavender and Rosemary also possess great antiseptic properties, but the powerfully (and to many, disagreeably) smelling Eucalyptus appears to have been much overrated. Those interested in the question may read a record of experiments made, in the *Text Book of Bacteriology*, written by Sternberg, published in 1897. The use of odour in protecting the plant producing it was investigated by Professor Tyndall, who made a series of experiments to test the absorption of heat by odorous vapours. As compared with unscented air the action is astonishingly powerful, Cassia,* it was found, had 109 times the cooling effect of fresh air. Perhaps the following table of Tyndall's may be of interest :—

Perfumes.	Absorption per 100.
Patchouli	30·0
Santal	32·0
Geranium (Pelargonium)	33·0
Oil of Cloves	33·5
Attar of Roses	36·5
Bergamot	44·0
Neroli	47·0
Lavender	60·0
Lemon	65·0
Portugal	67·0
Thyme	68·0
Rosemary	74·0
Oil of Laurel	80·0
*Cassia	109·0

There can be no doubt, therefore, that the volatilization of these essential oils is largely instrumental in protecting the plants producing them against the heat of the sun. Even the exquisite perfume of our beloved garden flowers serves to protect the blossoms and so lengthens the time in which they can attract their insect friends whose visits are so important for the production of fine seeds and the vigour of their race. They render our gardens not only more attractive, but more refreshing and health-giving for us. *H. H. Warner.*

The Future of the Potato.—I have been greatly surprised that so little notice has been taken of what, to my mind, is the very dangerous suggestion of Mr. Cuthbertson (p. 251) in regard to retaining seedling Potatos that are susceptible to Wart Disease. It is nearly twenty years since I first experienced the deadly destruction caused by this disease in the Potato crop. The area infected was a large rural village in the north-west midlands, where every cottage garden was so badly infected that very little more than a stone of sound tubers could be obtained from every sackful lifted, and this condition had prevailed for years. As the Potato crop is one of the mainstays of the workers' homes, this state of affairs was serious. A stock of immune varieties was obtained and distributed; they proved a God-send in that village, as they have done in hundreds of villages in our country. Since that period, I have had considerable experience in half-a-dozen counties where Potatos are largely grown, and I maintain that anyone who is familiar with the devastation caused by Wart Disease in the Potato crop (and I have seen an area of three acres rotten with it) cannot be otherwise than horrified to see this dreaded disease written of as a mere bogey. Our Potato breeders have done excellent work in raising good immune varieties possessing the necessary three qualities which make a good Potato, viz., good cooker, good cropper and good keeper. What could one wish for better than the following varieties : Immune Ashleaf, Arran Comrade, Catriona, King George, Great Scott, Majestic, Bishop, Kerr's Pink, Arran Victory and Golden Wonder ? The commercial grower, the exhibitor, and the epicure have their desires met in the above varieties. We still want more first-early immunes, but I am quite sure our Potato breeders will yet prove capable of producing them. Another aspect of the situation should, I think, also receive consideration ; that is, the export trade in seed Potatos. Good markets abroad can be obtained for certified clean stock, and the greatest danger to-day to the necessary clean bill of health is the prevalence of Wart Disease. I know of more than one commercial grower who could not obtain a certificate for export because he was too near an infected area. The excellent work on this subject carried out in the past by men of practical and scientific knowledge like Gaut, Gough, Snell, Malthouse, Bryan and others, cannot be lightly passed by ; rather let us aim at wiping out such a disease by clearing off the map all susceptible varieties. The powers that be have been far too weak-kneed in dealing with this question in the past, and vested interests have overruled common sense. *W. S. S.*

Gardeners' Pay and Status.—*H. B. O.* is lavish in his praises of the P.G.A. (p. 125), and Mr. Capp (p. 249) is also convinced this Association will improve matters for the professional gardener. I was a member of the old British Gardeners' Association in pre-war days—does the P.G.A. work on similar lines ? If so, I am afraid it will not make much headway. *H. B.* states that a £2 per week man is only worth that wage ; perhaps he is right, but I do not agree with him that if a man, knowing his worth, asks £4, he will nearly always get it. £4-a-week posts are few. I know from experience that many a good man, through no fault of his own, has been compelled to accept much lower wages. I started gardening when twelve-and-a-half years old, and have been at it for twenty-eight years, and force of circumstances compelled me to accept lower wages than I asked for. If *H. B.* had been in my position a year ago he would have found, as I did, that wages offered were low. I was offered nothing over 50s. Do the R.H.S. and the various local gardeners' associations advocate a good wage ? One does not see mention of such policies in their publications. Are they not more concerned with getting a greater membership, irrespective of the applicants' knowledge of gardening ? Again, to my mind, the various items on gardening in the daily press are not good for the gardening profession. What other profession publishes its knowledge in this fashion ? I have discussed this subject with many gardeners, and all agree that it is detrimental and should be discouraged. However, I have applied to the P.G.A. for its literature, and shall then judge whether it is worth joining ! *E. O.*

Arenaria norvegica.—In answer to Dr. Claridge Druce re Arenaria norvegica (see page 300), I am unable to confirm the suggestion that the plant was to be found on North Ronaldshay, Orkney Islands. Although not having access to Sowerby's *Flora* at the moment, I was in a position to consult that work when growing the plant two or three years ago, and then made a mental note of the reference quoted. The article stated that A. norvegica had been *reported* from North Ronaldshay, and, my authority being Sowerby, it would appear to have been substantially true at the time his *Flora* was published, although the statement may have been deleted from later editions. If, as Dr. Druce suggests, the record is possibly unfounded, this is an interesting point which may, perhaps, be definitely explained by someone more in touch with botanical investigation than myself, or by some reader who has been fortunate enough to visit North Ronaldshay in quest of plants. *L. B. C.*

VEGETABLE GARDEN.

RUNNER BEANS.

The Runner Bean ranks as one of the most important crops in the kitchen garden during the summer and early autumn, and rightly so.

To obtain good results, seeds may be sown early in May in boxes or pots of good, friable soil, consisting of two parts loam sifted through an inch sieve, one part leaf-soil, and one part well decayed horse manure, the two latter sifted through a half-inch sieve. A little silver sand may be added to keep the compost porous. For general cultivation, boxes about fifteen inches square and four inches deep will make ideal receptacles for the seeds ; crock them carefully, and place some rough material over the crocks to facilitate good drainage, then fill the boxes with the soil and press the seeds in edgeways about two inches apart ; cover them with soil, and firm the whole gently. Water the seeds in with a rosed can, and place the boxes in a vinery or Peach house that has been "started," covering them with paper to conserve the moisture. The paper should be removed when the seedlings commence pushing their way through the soil, and the boxes placed as near the glass as possible ; a suitable place for a week or so at this stage would be a heated frame where the plants will be close up to the glass, and at the same time, safe from night frosts ; afford plenty of air all day to promote sturdy growth.

As the plants gain strength, they may be removed to a cold frame and gradually hardened off preparatory to being planted out.

In the meantime, attention must be turned to the site they are to occupy. Select an open, sunny position, and if the ground has been well trenched and manured during the winter, so much the better, but if this has not been practicable, trenches about two feet wide and eighteen inches deep should be made, preferably running north to south. Thoroughly break up the bottom of the trench, and mix in plenty of rough garden refuse, especially if the subsoil is heavy. Then place some of the soil back again, incorporating with it some well-decayed farmyard manure. Place the rest of the soil on this, leaving a slight depression all along the trench to catch and conserve the rain-water, and so save much labour in watering. The sticks or poles may be placed in position about a week before planting time. Stout poles should be placed at each end and at intervals along the rows, and a strand of wire run along about six feet from the ground, and stretched as tightly as possible. If thin poles are used, one should be placed for each plant at about a foot apart, and tied firmly to the wire. Give the ground a light dusting of old soot and fork it in lightly, when all will be ready for planting. Some growers prefer long, bushy Pea sticks as supports, but these should be placed so that the tops are not too close.

Do not plant Runner Beans closer than a foot apart, for nothing is gained by overcrowding them. Provided the plants have been hardened off, they may be planted out about the first week in June, choosing a warm day when the soil works well. Lift the plants from the boxes with as much soil to the roots as possible, plant them firmly, and, when the row is completed, water them in if there is no danger of frost or a cold night, from which the plants should be protected with tiffany or leafy branches ; the plants will take no harm for a day or so if watering is impracticable. The young growths may possibly need assistance up the poles or sticks, and each one should be tied to encourage it to climb ; afterwards, there will be no trouble in this respect. If the weather proves warm and dry, a good syringing overhead every afternoon will greatly benefit them, but they need not be given a lot of water at the roots for some time, and if the ground has been well prepared, they will not require it. Later on, when the plants are well up the supports and bearing heavy crops of Beans, they will need copious supplies of water, and occasionally a good soaking of liquid farmyard manure, diluted with soft water if possible; in any case, only water that has been exposed to the sun should be used. Cold water from a main is likely to cause dropping of the flower buds, which is most likely to occur when the plants are producing their first trusses of bloom. Hoe between the rows frequently, and, if drought sets in, mulch the ground about the roots with stable litter, or any material that is not of close texture, and will allow a certain amount of sun and air to reach the roots.

If Runner Beans are required to produce good specimen pods for exhibition, they will, of course, require extra attention. The growths should be kept well thinned, and each truss of flowers should be thinned, two or three Beans only being allowed to develop from each, and these should hang clear of the vine and foliage so that they may develop into long, straight pods. The chief object is to have fine, long pods, devoid of any coarseness of texture, as this will tell against them in close competition. Some varieties are apt to produce a coarser type of pod than others when size is aimed at, and these should be avoided. The pods should be picked so soon as ever they are ready, and the ends placed in cold water in a cool room, when they will keep in good condition for several days. They should be absolutely smooth, with no suggestion of swelling seeds within, and should be well coloured. Attractive arrangement is important, especially in single dish classes. Twelve Beans are usually asked for, and these look best if arranged on dark green foliage on a plate. It is a mistake to use too large a dish, as is often done, as it has a dwarfing effect on the pods.

Many growers have not the facilities for sowing Runner Beans in pots or boxes as suggested, but they need not despair, as very fine produce can be procured by sowing them out-of-doors. If outdoor sowing is practised, the supports should be placed along the rows previous to sowing the seeds. The seeds should be placed about six inches apart, making the holes with the trowel and placing one seed in each, edgeways, which reduces the risk of their rotting off if the weather should be cold. If the seeds germinate well, as they should do, every other seedling may be discarded.

All pods should be picked so soon as ready, as, if allowed to hang on the plants too long, they not only become tough and unpalatable, but retard the progress of others. All surplus should either be sold or sent to the kitchen to be salted down for winter use. The latter is an easy process, and the Beans will be much appreciated when vegetables are scarce. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

ORDER OF FLOWERING AND POLLENATION OF FRUIT BLOSSOMS.*

(*Concluded from p.* 333).

INSECT VISITORS TO FRUIT BLOSSOMS.

I HAD hoped to devote a good deal of time to the insect visitors to fruit blossoms, but the length of the paper does not allow it.

There are a great many different kinds of insects that visit fruit blossoms, especially the Apple.

For several years I made brief notes on those I noticed and added up their numbers, which are given in the attached table. I am glad to state, since I made my observations as a mere naturalist, Mr. G. Fox Wilson, as a trained entomologist, has made a far more complete list at the Royal Horticultural Society's Gardens, at Wisley, Surrey, and I would refer anyone interested in the subject to his well-illustrated report in the *Journal of the Royal Horticultural Society* for 1926.

Mr. Fox Wilson's and my records differ in some ways. The Royal Horticultural Society's Gardens are surrounded by common and woods; there was not a large acreage of fruit, and the nearest hive of bees was about three-quarters-of-a-mile distant, so wild insects were very numerous and hive bees not so abundant.

At Wye there is a considerable acreage of Cherries, Apples and other fruits, and a good many hives of bees are kept; the surrounding land is arable land and sheep pasture, which are not very favourable habitats for pollenating insects.

All entomologists who have studied the subject of fruit pollenation agree that the bee family, owing to the structure of the insects and their habit of keeping to one kind of flower on a journey, are by far the best fruit pollenisers of all insects.

The humble bees and the small wild bees do splendid work, but they are out of human control and cannot be increased in number. With high cultivation, wire fences replace hedgerows; so that the banks and woods where the wild bees make their home decrease in area; thus the value of the hive bee relatively increases.

Where there are large blocks of fruit trees the pollenation by insects is out of proportion to the capacity of the local wild insects, and it is therefore of great value to place hives of bees in different parts so as to have them near the Black Currants and Cherries and other fruits to carry pollen when the weather is favourable.

NUMBERS OF DIFFERENT KINDS OF INSECTS VISITING FRUIT BLOSSOMS.

RECORDED BY C. H. HOOPER AT WYE, KENT.

Fruit.	Hive bees.	Humble bees.	Small wild bees (Andrena & Halictus.)	Blue-bottle flies.	Other flies.	Beetles.	Ants.	Earwigs.	Thrips.	Other Insects.	Notes.

The American fruit growers keep bees extensively for the fertilisation of the blossoms rather than for the honey. In England one finds that many of the most painstaking and successful fruit growers keep bees with the object of increasing their crops.

It is advisable to distribute the hives rather than to have them all in one spot, the ideal arrangement being one hive to each acre of fruit trees.

It may be found practicable to take hives to fruit plantations just before blossoming time, and afterwards to remove them to where there is more diversity of flowers, in the same way that hives of bees are taken to the Heather moors. I have for three years taken out a hive to a Cherry orchard just before blossoming time, and brought it home after flowering was over, with satisfactory results.

It is stated that bees fly from their hives against the direction of the wind and have it with them when returning laden with pollen and nectar, so that it may be advisable for hives to face the direction of the prevailing wind.

As it is important to have the bees in the hive strong and in large numbers ready for their work in the early spring, they should, therefore, be left with sufficient food in the autumn for the winter, and will be benefited by being given syrup in early spring.

There are three ways of managing the bees on a fruit farm:—(1) For the owner to look after them; he may not have time or may not like bees, so (2) he can get one of his men to look after them, giving him a little higher wage; or (3) he can allow a bee-keeper to keep his hives in his orchards or even pay him, say, 5s. a hive, for the use of his bees.

I asked Messrs. Chivers and Sons, of Histon, Cambridge, their opinion about bees, and Mr. H. J. Chivers very kindly replied: "I am afraid that, unlike our American friends, we are unable to state very definitely the effect of bees on the pollenation of fruit. To our minds, it entirely depends on the type of weather just before and during the flowering of the fruit as to whether the bees are actually a great deal of good or not. However, as we keep about 500 stocks of bees, you will realise that we do believe in them."

CONCLUSIONS.

To summarise this paper, the points I wish to emphasise are:—1. That, if there are not sufficient wild insects, especially humble bees and the small wild bees, in the neighbourhood to pollenate the crop efficiently, pursuade someone to bring his hives of bees to your plantations and have the honey he gets as his reward.

2. In planting a new plantation or orchard of fruit trees, choose two or more varieties that flower about the same time, avoiding planting together varieties of Cherries that are inter-sterile; alternate the varieties every two or three rows.

3. Where trees of one variety have been planted in large numbers, interplant or regraft one tree in nine with another variety in order to get cross-pollenation, say every third tree in each third row.

Finally, I have to thank Mr. F. I. Neame and Mr. H. Stevens for allowing me the run of their farms in which to make experiments, and for answering many questions, also Mr. H. S. Rivers and Mr. E. A. Bunyard for making records of the order of flowering. I thank Mr. F. J. Chittenden, Director of, and Mr. A. N. Rawes, Experimenter at, the Royal Horticultural Society's Gardens, also Mr. M. B. Crane for much of the information included in this paper, and last, but not least, Mr. F. Edenden, of Wye, who prepared most of the lantern slides for me.

The paper was followed by a good discussion in which Messrs. H. V. Taylor, G. Fox Wilson, W. S. Rogers, A. H. Hoare, Stephen Mount, and H. Grainger took part.

---

* A paper read before the Royal Society of Arts, Wednesday, February 13, by Mr. Cecil H. Hooper, F.L.S., of Wye, Kent.; Mr. H. V. Taylor, O.B.E., Commissioner for Horticulture, Ministry of Agriculture, presided.

SOCIETIES.

ROYAL HORTICULTURAL.

May 7 and 8.—There was a bright and interesting show at the new Horticultural Hall, Westminster, on these dates, in connection with the fortnightly meeting of the Society. Perhaps because the great Spring Show is to be held in a fortnight's time, Orchids were not so numerous as formerly. The Orchid Committee recommended one First Class Certificate to a new hybrid Orchid. There was a considerable variety of general flowers, and the chief were Hippeastrums, Nemesias, Roses, Carnations, Calceolarias, and alpines. The Floral Committee recommended six Awards of Merit to novelties and selected seven seedling double Primroses for trial at Wisley. Daffodils and Tulips continue in considerable beauty and, besides several handsome groups, the Committee had many novelties, of which they recommended one for the First Class Certificate and four for Awards of Merit. There was nothing before the Fruit and Vegetable Committee.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. R. G. Thwaites, Mr. A. McBean, Mr. J. C. Cowan, Mr. T. Armstrong, Mr. H. G. Alexander, Mr. J. E. Shill, Sir Frederick Moore, Mr. Arthur Dye, Colonel Stephenson Clarke, Mr. Lionel de Rothschild, Mr. Fred K. Sander, Mr. E. R. Ashton and Mr. C. H. Curtis.

First Class Certificate.

Sophro-Laelio-Cattleya Yokohama (S.-L.-C. Prince Hirohito × Cattleya Hesperus).—A very beautiful hybrid of fine size and form. The broad petals are salmon coloured, with soft, violet-rose veins, and the narrower sepals are of similar colour, but with heavier and straight veins of violet-rose. The lip is ruby-crimson, with rich old-gold shading in the throat and some bright gold veins. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green, Surrey.

Groups.

The only group of any pretensions on this occasion was one arranged by S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton. In this display were good examples of Cymbidium Lowianum, Dendrobium infundibulum, Dichrysotoxum, D. Draconis, Oncidium McBeanianum, O. amplicatum, Cattleya Skinneri var. alba, Lycaste Skinneri var. alba, the greenish-yellow Polystachya lutescens, Phalaenopsis Rimestadiana, Odontioda Zephyr, Phaius Sanderianus, Cypripedium Nandii, Odontoglossum excellens, Saccolabium ampliatum var. majus, and the bright rose-red Trichopilia marginata. This was a very interesting display.

Messrs. Stuart Low and Co. had a small group which contained Cattleya Lawrenceana—now seldom seen, Laelio-Cattleya Luminosa in fine form, L.-C. G. S. Ball, Brasso-Cattleya André Maron, and a large example of Eria convallarioides. Mr. J. Evans showed Laelio-Cattleya G. S. Ball.

Robert Paterson, Esq. (gr. Mr. Merry), showed Odontoglossum Naomi, Stonehurst var., with rich red markings, and also the deep-hued Miltonia Memoria var. H. T. Pitt; Mrs. Carl Holmes and Gus Mayer, Esq., showed individual plants before the Committee.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. A. Turner, Mr. J. T. West, Mrs. Ethel M. Wightman, Mr. J. M. Bridgeford, Mr. E. R. Janes, Mr. A. E. Vasey, Mr. Hugh Dickson, Mr. M. C. Allwood, Mr. David Ingamells, Mr. W. B. Gingell, Mr. R. Findlay, Mr. William Howe, Mrs. Helen Lindsay Smith, Mr. Charles E. Pearson, Mr. B. R. Long, Mr. G. W. Leak, Mr. W. Champion Hackett (visitor), and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. W. G. Baker, Mr. F. G. Preston, Mr. G. Reuthe, Mr. L. R. Russell, Mr. A. Bedford, Lady Beatrix Stanley, Mr. James Comber, Mr. T. Hay, Mr. Eric M. Marsden-Jones, Mr. C. Williams, Sir William Lawrence, Bart., Mr. Gerald W. E. Loder, Mr. R. C. Notcutt, Hon. Henry D. McLaren, the Marquess of Hartington, Mr. T. W. Taylor, and Mr. N. K. Gould, Secretary.

Awards of Merit.

Anthurium Scherzerianum var. Ne Plus Ultra.—A magnificent spathe of more rounded shape than the species and rich scarlet colour. Shown by Messrs. Sanders.

Carnation Guy Allwood.—This appears to be a very desirable greenhouse Carnation. The flowers are large, of good form and of pleasing pink shades of colour. The broad petals are evenly serrated and the blooms are decidedly fragrant. Shown by Messrs. Allwood Bros.

Loasia acanthifolia.—This hardy annual is rarely seen in cultivation. The plant shown was raised from seeds collected by Mr. Clarence Elliott in south Chili, where it was growing at an altitude of from 5,000 feet to 6,000 feet, in a Nothofagus forest. As with others of the genus, the plant is set with stinging hairs which will penetrate stout gloves. The pinnatifid opposite leaves are decidedly suggestive of those of an Acanthus in miniature. The stout flowers are solitary on fairly long pedicels, and of bright orange colour with deeper coloured centres. The calyx segments are curiously hooded. Shown by Mr. Clarence Elliott.

Prunus nana.—The dwarf Russian Almond is stated to have been cultivated in this country since 1683. An illustration of a paler form is given in *Bot. Mag.*, t. 161. It is a dwarf bush, and, when freely flowered, is very attractive. The flowers were of deep pink colour. Shown by Mrs. Philip Martineau, Sunny Corner, Ascot.

Ramondia Nathaliae.—An excellent plant of this charming alpine was shown. The flowers were mostly solitary, erect, and of beautiful wistaria-blue colour, deepening at the margins. There is a golden base to the petals. Shown by Mark Fenwick, Esq. (gr. Mr. F. Fustin), Abbotswood, Stow-in-the-Wold.

Tropaeolum azureum.—A slender, twining, greenhouse species from Chili. The leaves are tiny for the genus and the bright blue flowers are also small, although very attractive. Shown by Mr. Clarence Elliott.

For Trial at Wisley.

Mr. P. Murray Thomson, Downshill, Bridge Sollers, Hereford, showed twenty-four distinct seedling double Primroses. In some the doubling was somewhat perfunctory, but the best were very promising, and seven of them were slected for trial at Wisley.

Groups.

On a considerable floor space, Messrs. Sutton and Sons displayed a large number of splendidly grown Nemesias in pots. As is usual with the Reading exhibits, the arrangement showed great skill and taste. Most of the plants were arranged in circles of distinct shades of colour, and we admired especially Scarlet, Crimson, Blue, Rich Orange, Rose Pink and White Gem.

A large group of excellent Hippeastrums was contributed by Mrs. Walter Burns (gr. Mr. G. W. Wright), North Mymms Park, Hertford. These were mostly of a good white, but rose-pinks, crimsons and other shades of colour were equally well represented. Messrs. Stuart Low and Co. associated good Hippeastrums with an interesting variety of other greenhouse plants. Eric Wettern, Esq. (gr. Mr. A. Carter), South Croydon, set up a pleasant group of blue Cinerarias. An exhibit of large-flowered Calceolarias shown by Mr. Alfred Dawkins illustrated a very desirable strain as well as good cultivation. B. Wilkinson, Esq. (gr. Mr. H. Brown), Silverlands, Chertsey, set up a small group of good Schizanthuses. Messrs. J. Cheal and Sons showed the first Dahlias of the year, as cut flowers.

Good exhibits of Roses were displayed by several trade firms. Messrs. B. R. Cant and Sons and Mr. Elisha J. Hicks had many vases of excellent H.T. varieties, while Mr. J. H. Pemberton and Messrs. Frank Cant and Co. grouped very good Polyantha varieties. Their customary exhibits of fresh Carnations were arranged by Messrs. C. Engelmann, Ltd., Messrs. Allwood Bros. and Messrs. Stuart Low and Co.

A large collection of the varieties of Anthurium which have unusually large spathes were displayed by Messrs. Sanders in front of a row of particularly well-flowered plants of Dendrobium thyrsiflorum. The Anthuriums included Magnum Bonum, a good spotted variety; Rothschildianum and its varieties pallens, a pale creamy-white, and amabile, and a pretty rose-coloured variety of Dalliereanum. Mr. Baldwin Pinney again showed Sweet Violets.

Alpines were shown extensively. Messrs. Waterer, Sons and Crisp, displayed good breadths of Polemonium grandiflorum, Meconopsis Baileyii and other seasonable flowers; Messrs. B. Ladhams, Ltd., included sprays of Pyruses and Berberises with border flowers in quantity. Mr. Gavin Jones had an attractive rock garden containing masses of Euphorbia polychroma, dwarf Irises, Saxifrages and Primulas. Rock garden exhibits were also staged by Mr. Geo. E. P. Wood, Messrs. Casburn and Welch, Mr. G. G. Whitelegg, Messrs. C. H. Bloom and Son, Mr. Stephen Sim, Messrs. Baker and the Misses Hopkins.

Messrs. Maxwell and Beale had a bright display of hardy shrubs and border flowers. Messrs. W. H. Rogers and Son introduced colour with Alyssum saxatile var. sulphureum, Gentians and Aubrietias. Mr. Clarence Elliott staged alpines in pans, and included good Androsaces, Gentians and Daphne rupestris (petraea). Messrs. M. Prichard and Son filled a whole table with Azaleas, Brooms and many alpines.

The Sewell Medal, offered for the best six pots or pans of alpines shown by an amateur, induced good competition. The best of the seven exhibits was staged by Mark Fenwick, Esq., Abbots Wood, Stow-in-the-Wold, who had excellent specimens of Lewisia Howellii, Androsace Watkinsii, Daphne rupestris (petraea) var. grandiflora, Haberlea Ferdinandi-Coburgi and Polygala Vayredae. On a floor space, Messrs. L. R. Russell, Ltd. had a pleasing group of Pyruses, Prunuses and dwarf Japanese Azaleas.

Messrs. Patricks staged hardy shrubs, and Mr. G. W. Miller and Mrs. Alan Fremantle showed Polyanthuses and Primroses. Mr. James Douglas had an excellent group of his show and alpine Auriculas.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mr. J. D. Pearson, Mr. G. W. Leak, Mr. Peter R. Barr, Sir A. Daniel Hall, Mr. W. R. Cranfield, Mrs. Brodie of Brodie, Mr. F. H. Chapman, Mr. F. A. Secrett, Mr. W. Poupart, Mr. Charles H. Curtis, Mr. J. L. Richardson, Mr. G. Monro, Mr. W. F. M. Copeland, Miss E. Willmott and Mr. A. Simmonds, Secretary.

First Class Certificate.

Narcissus Daphne.—This beautiful double-flowered Narcissus received an Award of Merit on May 8, 1917, and on April 22, 1924, it was awarded a First Class Certificate, but for no expressed purpose. This certificate was confirmed at this meeting, it being awarded on account of the variety's value as a market variety for cutting from the open, and for garden decoration purposes. It has all the qualities of a good market Narcissus, the very double flowers being compact and shapely, pure white, and charmingly fragrant, while they are carried well on erect, but not stout, stems. This Narcissus was also recommended for trial at Wisley. Shown by Messrs. Seymour Cobley, Ltd.

Awards of Merit.

Narcissus Recessional.—A grand Poeticus variety, which received an award as a show flower. The flowers are of fine substance, the broad, reflexed and curled segments being pure white, while the flattened crown is primrose-yellow in the centre and rich orange on the frilled margin. This variety was raised and shown by Mr. F. H. Chapman, Rotherside Gardens, Rye.

N. Bridegroom.—A lovely bicolor Barrii Narcissus, with broad, waved perianth segments of fine substance, slightly incurved on the margins and pure, creamy-white in colour; the prominent cup is rich yellow, strikingly edged with orange. This variety was raised by Mrs. Brodie of Brodie, but was shown by Mr. R. F. Calvert.

N. Huon.—A Poeticus variety of outstanding merit, which should prove popular as a market flower. It has irregularly waved, chalky-white, rounded segments, and a small, rich yellow corona edged with reddish-orange. It was raised by the Rev. G. H. Engleheart, and exhibited by Mr. F. A. Secrett.

N. Brimstone.—A Trumpet Daffodil of high quality, its curled perianth segments and long trumpet, frilled and broadly recurved at the mouth, all being of a rich, sulphur-yellow. Raised by the Rev. G. H. Engleheart and shown by W. B. Cranfield, Esq., East Lodge, Enfield Chase.

Groups.

Narcissi were again in evidence at this meeting, and there were a few Tulips. Messrs. Barr and Sons had a grand group of the former, excellently arranged, their best blooms being of such golden Trumpet sorts as Prince of Wales, Gold Sand and Fantin Latour; and a grand seedling Barrii hybrid, No. 348, of outstanding merit, together with Salembo, Gallipoli, Beersheba, Bonfire, Mrs. E. C. Mudge, Silver Gift, and numerous Poetaz varieties.

Mr. Herbert Chapman had a choice collection of Narcissi, but, unfortunately, many of his finest were under numbers only. Among named sorts, Savonarola, Ring-o'-Roses, Rheingold, Water Lily and Palma attracted special attention.

Among the Narcissi set up by Messrs. Cartwright and Goodwin, Ltd., were good specimens of Tenedos, Gallipoli, Dosoris and Robin Redbreast. Mr. F. A. Secrett showed Poetaz Narcissi extensively, his blooms being massed very effectively, while Messrs. R. H. Bath, Ltd., had a small collection which contained several popular sorts, together with a few good seedlings under numbers.

Messrs. G. W. Miller had a small, mixed collection of Narcissi and Tulips, while noteworthy sorts in the mixed group set up by Messrs. D. Stewart and Son were Croesus, Red Beacon and Orange Cup, among Narcissi, and William Pitt, Fra Angelica, Artemis and Arethusa, among Tulips.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. J. Cheal, Mr. H. S. Rivers, Mr. W. H. Divers, Mr. J. Wilson, Mr. E. A. L. Laxton, Mr. A. Bullock, Mr. R. H. Hall, Mr. A. Poupart, Mr. W. Poupart, Mr. G. F. Tinley, Mr. C. G. A. Nix and Mr. A. N. Rawes, Secretary.

This Committee had no business of any description to conduct.

ROYAL HORTICULTURAL OF IRELAND.

The Spring Show, held by permission of the Earl of Iveagh, in the Covered Court, Earlsfort Terrace, Dublin, on April 17 and 18, proved a pleasant and successful function under ideal weather conditions. Daffodils were fairly plentiful and of high quality, in spite of "London calling," and the consequent absence of the Irish trade growers. Commencing with alpines, the chief winners in nine classes were Mrs. Butler, Priestown, Co. Meath (gr. Mr. J. Manning), who, in the tall order for a table twelve feet by four feet, won outright the Challenge Cup presented by Lady Greer, O.B.E.; Miss Wynne, Tigroney, Co. Wicklow, and Miss Osborne, Drogheda, following. Mrs. Butler won the Cup presented by the late Major Butler for twelve pots or pans of rare alpines, and also the old Irish Silver Cup presented by the Rt. Hon. Andrew Jameson, for the best exhibit in the premier six classes. Mrs. Jameson (gr. Mr. P. Cullen), excelled with twelve pots or pans of alpines, not exceeding six inches in diameter, and also with twelve Saxifrages, distinct; Mrs. Croft, Brackenstown House, Co. Dublin (gr. Mr. G. Naylor), secured the Farrabond Cup, presented by Miss Osborne for the best twelve pots or pans of hardy Primulas, distinct.

Pot plants were unusually well shown, Mrs. McCabe, Trimleston House, Co. Dublin (gr. Mr. T. McGauley), having the best six Primula obconica, with Major Vincent Kelly (gr. Mr. J. McDermott) and C. Wisdom Hely, Esq. (gr. Mr. J. H. Orr), second and third respectively. Six table plants were shown by the Hon. A. E. Guinness (gr. Mr. W. Stevens); Mrs. Bernard (gr. Mrs. J. Dawson), and Madame Fottrell (gr. Mr. W. Taylor), who won in this order. C. Wisdom Hely, Esq., the Hon. Mrs. Chas. Guinness (gr. Mr. J. Corrig), and Mr. W. H. Odlum, were first and second respectively, for six Cyclamens. Deutzias, always well done in Dublin, found C. Wisdom Hely, Esq., first and Major Kelly second; the latter had the best three Mignonettes, with Captain Daly (gr. Mr. J. Murtagh) next. Six pots of grandly grown Freesias secured a first prize for the Hon. Gordon Campbell (gr. Mr. J. Cook), who was without a competitor. Spiraeas secured first and second prizes for C. Wisdom Hely, Esq., and Madame Fottrell. Calceolarias were best shown by Mrs. McCabe, while fine sixes of Schizanthus were staged by W. Hely, Esq., Major Kelly and Mrs. McCabe, who won as placed.

Good lots of two dozen pots or pans of bulbous or tuberous-rooted subjects made a bright display, W. Hely, Esq., winning Messrs. Drummond's first prize, with Mr. Alfred West (gr. Mr. C. T. Coster), second, and Madame Fottrell, third. For six pots of single Tulips, Mrs. McCabe, W. Hely, Esq., and Major Kelly won as placed. Mrs. McCabe's six pots of double Tulips were the best set and of sufficient merit to receive Bishop Plunket's Challenge Cup as the best exhibit in this section; W. Hely, Esq., was second. The best twelve Hyacinths came from Mrs. McCabe, while Messrs. M. Rowan and Co.'s prize for six pots of Hyacinths was won by Major Kelly, with Madame Fottrell second.

In the premier class for Daffodils, thirty varieties, distinct, three stems to a vase, competing for the Lord Ardilaun Perpetual Challenge Cup, and money prizes presented by Messrs. Hogg and Robertson, Dublin, Mrs. Alfred West won for the sixth consecutive year, with her Kilcroney blooms in grand form, but there was little to choose between her flowers and those of Miss Hely-Hutchinson (gr. Mr. J. Shekelton), and these prize-winners, with the Hon. A. E. Guinness, and the Misses Bird (gr. Mr. J. Smith) divided honours in the dozen smaller classes.

Two excellent stands of Roses, of twelve blooms, were shown by Mrs. West, first, and W. Hely, Esq., second. Mrs. West won outright the Challenge Bowl presented by Mrs. Bland, for a dozen bunches of Violets. A fine stand of two dozen vases of hardy flowers found Mrs. Stephenson (gr. Mr. M. Buggle) finally winning Captain Riall's handsome Challenge Cup, Mrs. Jameson having the best twelve vases, with the Misses Bird the next best. Mrs. Stephenson secured Messrs. Watson's (Killiney Nurseries) prize for the best dozen hardy shrubs in flower, smaller classes being filled by those already mentioned. Classes for Primroses in variety were particularly well filled, showing both variety and high quality. In the important class for eighteen vases of bulbous, tuberous, or rhizomatous plants, flowered in the open air, fine displays came from Miss Wynne and Mrs. West.

Fruit was merely represented by a few nice dishes of Apples and one of Pears, the prize-winners being the Hon. Kathleen Lawless, Lyons, Co. Kildare (gr. Mr. W. Hall), Mrs. H. E. Richardson, the Sisters of Charity, Bray (gr. Mr. J. Tully), and Mrs. McCabe. Cucumbers won first prize for The Hon. K. Lawless, with Mrs. McCabe, and the Hon. Gordon Campbell chiefly leading in the single dish classes, the first named having an excellent collection of six vegetables. Other prize-winning collections came from Mrs. McCabe, Miss Darley (gr. Mr. P. Mohan), Miss Cunningham (gr. Mr. J. McLindon), Mrs. Tisdall (gr. Mr. Dougherty), and Mrs. Stapleton (gr. Mr. P. J. Clinch).

Special exhibits did much to enhance the general effect, and they taxed to the utmost limits the space the capacious building afforded. A Gold Medal was voted to Messrs. Wm. Watson and Sons, Ltd., Killiney Nurseries, Co. Dublin, for a fine group of flowering shrubs; Silver Medals being awarded to Messrs. Charles Ramsay and Son, The Royal Nurseries, Dublin, and to Mr. A. L. Speirs, Burtown Nurseries, Co. Kildare, for excellent groups. A Silver Medal was awarded to Miss Gordon, The Curragh, for a table of Primroses in variety, and to Miss Hume, Dublin, for a similar exhibit. Bronze Medals were awarded to Miss Johnston, Bray, and Mrs. Johnston, Kinlough, Co. Leitrim, for attractive tables of hardy flowers; and to Mr. R. C. Cherry for a model garden. A Cultural Certificate was awarded to Mrs. Whyte, Balbriggan, Co. Dublin, for a collection of Mesembryanthemums grown in the open.

GLAMORGAN SPRING FLOWER AND DAFFODIL.

This Society holds its annual show in various places in the county, and this year's venue was Porthcawl, where the show was held in the Pavilion on April 24. The excellent backgrounds, the provision of uniform vases and baskets, together with the high standard of the exhibits, made it a model show, and the Hon. Secretary, Miss Ackland-Allen and her Committee are to be congratulated on the excellence of the arrangements.

The show was well supported by the trade. The Donard Nursery Co. had an imposing group of Narcissi, among their best varieties being Silver Plane, Eskimo, Blizzard, Festive, Tempest, Slieve Donard, Silver Fox and Market Glory. Messrs. Barr and Sons had an equally meritorious exhibit of Narcissi, which included Beersheba, Red Gauntlett, Caedmon, White Nile, Ben Alder, Kantara and many others. Messrs. Robert Veitch and Son exhibited flowering shrubs and alpines. Messrs. Treseder and Son had decorative plants, and Messrs. H. and W. Evans, Llanishen, had a well-arranged group of alpines and shrubs.

The awards in the competitive classes were well contested. Eveline, Lady Byass won the first prize in the class for three blooms each of fifteen varieties of Narcissi, her best varieties being Silver Fox, Macebearer, Croesus, Ibis and Lord Roberts. Mrs. Mackintosh of Mackintosh was a good second, and W. B. Hallowes, Esq., third. For twelve varieties of Narcissi, Eveline, Lady Byass again led, followed by Mrs. Mackintosh of Mackintosh, with Lady Llewellyn third.

The classes for hardy spring flowers other than Daffodils, were well filled with exhibits of very high quality. H. E. David, Esq., had the best six alpines, followed by Lady Llewellyn, who was a good second. For a collection of unforced alpine flowers, fifteen varieties, H. E. David, Esq., again led; second, Major C. T. Edmondes, who included an excellent plant of Androsace helvetica in his exhibit; third, Mrs. D. C. Edmondes; fourth, Mrs. Nichol, For eight varieties of unforced spring flowers, Miss E. Booker was first, Alan Gibbs, Esq., second, and Mrs. Knight third.

For six varieties of hardy Primulas, Eveline, Lady Byass led, followed by Major C. T. Edmondes. For four varieties of Polyanthus, Sir Geoffrey Byass won with excellent plants; second Eveline, Lady Byass; third, Mrs. F. Leigh. For six varieties of Primroses, Eveline, Lady Byass won with a very even lot; second, Sir Geoffrey Byass; third, Mrs. Nichol.

Captain A. Talbot Fletcher had the best collection of flowering shrubs, also the best exhibit of fifteen trusses of Rhododendrons, which included good flowers of R. sperabile, R. niveum, R. Thomsonii and R. caloxanthum. Lady Blythwood won in the class for twelve Anemone blooms; second, Mrs. D. C. Edmondes; third, Mrs. G. Crawshay.

For the best bowl of Daffodils arranged for effect, Miss Ackland Allen led with an excellent arrangement of mixed blooms; Alan Gibbs, Esq., was a close second with a very tasteful bowl of N. poeticus and Prunus Pissardii; third, Miss E. Booker. For a basket of spring flowers arranged for effect, Lady Byass gained first prize; second, Mrs. Knight; third, Miss M. Knight.

In the smaller classes, the leading prize-winners were Eveline Lady Byass, Mrs. Mackintosh of Mackintosh, W. B. Hallowes, Esq., Mrs. Nichol, Mrs. Knight, Mrs. D. C. Edmondes, Miss Dulcie Booker, E. U. David, Esq., Mrs. C. Gilberton and Lady Llewellyn.

NORFOLK AND NORWICH SPRING FLOWER SHOW.

This is the Centenary year of the Norfolk and Norwich Horticultural Society, for it held it first exhibitions in 1829. It was therefore very encouraging to find that the entries upon the occasion of the Spring Flower Show, held on April 18, 19 and 20, exceeded the average of the past five years; indeed, they reached pre-war numbers. Narcissi, owing to the extreme cold weather, were not quite so long in the stem as usual, and it was also noticed that several of those varieties which are usually over before the show date, were at their best this year.

Captain A. Sandys-Winsch, the Secretary, won the Cup for twenty-four varieties of Narcissi and Daffodils, distinct, and as this is his third successive win, the trophy now becomes his own property. This grower is making good strides in the raising of seedlings, and many on his stand under numbers foretold of a demand for them when they are put into commerce.

Colonel H. G. Barclay (gr. Mr. W. C. Barrie), also had an exceptionally good lot of quite up-to-date named sorts. The smaller classes, especially in the Trumpet section, were very attractive, many new kinds being included in them. The prizes for vases, baskets and other decorative classes were all well contested.

In the general cut flower section, Carnations were predominant and Colonel Barclay's blooms were far away the best. In the classes for greenhouse flowers, hardy flowers and hardy outside-grown flowering shrubs, J. A. Christie, Esq., M.P. (gr. Mr. Sam High), Framingham, took three first prizes; among his hardy flowers was a good vase of the brightly coloured Tulipa praestans, while of the flowering shrubs, Magnolia Kobus and Osmanthus Delavayi were outstanding. Violets from Gerald Gurney, Esq. (gr. Mr. F. J. Endersley), Keswick Hall, Norwich, were a meritorious feature.

Pot plants are always a feature of this show, and the splendid collection on a table space eight feet by three feet, exhibited by Mrs. H. J. Copeman (gr. Mr. Mitchell), 111, Newmarket Road, Norwich, was outstanding, containing exceptionally well-grown Calceolarias, Schizanthuses, Primulas, Cinerarias, etc., which were literally sheets of bloom. Mr. Ernest Bond, Newmarket Road, also had a fine group, while he secured special prizes for Cinerarias and other pot plants. Cyclamen were shown extensively, wonderful plants being staged by Colonel H. G. Barclay and Gerald Gurney, Esq., Fruits and vegetables were not a strong feature.

The trade assisted splendidly in making the show of educational worth. Messrs. Daniels Bros., Ltd., had bulbous flowers, Irises and Freesias being their outstanding features. Messrs. Allen had a beautiful display of forced Roses; so also had Messrs. A. Reeves and Co. Messrs. Allwood Bros. and Messrs. C. Engelmann, Ltd., both had effective displays of Carnations, while Messrs. Baker had rock plants in great variety. Messrs. G. W. Miller had hardy flowers and rock plants, and Messrs. R. Winder, Ltd., had a good display of forced shrubs and rock plants. Without doubt, the best display of the trade section was that of Daffodils set up by Messrs. R. H. Bath, Ltd., some really grand blooms being shown. Although not a trade exhibit, special mention may be made of the collection of Roses in pots, staged by an enthusiastic amateur, Dr. G. E. Deacon, of Brundall. It well deserved the Gold Medal awarded.

ANSWERS TO CORRESPONDENTS.

Chrysanthemums.—*G. F. W.* Watering Chrysanthemums immediately they are potted is not to be recommended. Provided the plants are well supplied with water before potting takes place they should receive no water at the roots for several days afterwards, especially if they are placed in cold frames. When water should be applied at the roots will depend very much on outside conditions, but even should the weather prove hot, they should not be watered-in at once as spraying should prove sufficient, but the lights should be left on for a short time, although air should be given during the day.

Grass Tennis Lawn.—*Enquirer.* The Construction of your tennis lawn is perfect, and the depth of soil is sufficient for its maintenance. There may be many reasons which would account for the failure of the finer grasses. A new lawn must be kept under proper control from its inception, and in your case, we are inclined to think that this has not been done. No matter how careful one may be in preparing the bed, weeds generally appear later. The choice of seeds is also of great importance, and if you did not specify a particular mixture, it is probable that your seeds contained a percentage of Rye grass. It is also probable that seeds may have been carried by the wind or by birds from surrounding areas and deposited on your lawns. The best remedy would be to remove the affected parts and re-lay with a good textured turf. If relaying is out of the question, give fortnightly dressings of sulphate of ammonia applied in showery weather, or watered in, at the rate of 1¼lb. to forty square yards. When the grass is sufficiently long, it should be cut closely with a scythe, then mown with a mower; continue these details until you are satisfied the fine grasses are responding to the treatment. Sea sand would not eliminate the trouble.

Grapes Disfigured.—*W. P.* The Grapes sent for examination are healthy and stoning well, but are suffering from an injury known as scalding, which frequently occurs when the berries are about half-grown. In some cases only a few berries here and there may be affected, in others the whole side of a bunch is damaged. The injury is caused by late or imperfect ventilation on bright, sunny mornings while the internal atmosphere is heavily charged with moisture. When airing is done properly the moisture dries slowly, before the sun gains much power, with the result that no scorching takes place. The stoning period is a trying time and sufficient fire-heat should be given to allow of the admittance of a constant supply of fresh air both day and night. Give your Grapes plenty of time during this period, avoid high temperatures and too much atmospheric moisture, and you will not be troubled further with scalding.

Hard Tennis Court.—*W. J. T.* The type of hard tennis court you purpose laying down is not to be recommended. The construction up to a point is excellent, but to spray the surface with the solution mentioned would not give you the desired results. The surface would be injuriously affected by sun and frost and in all probability would become a source of trouble. If you are desirous of having a hard court, we suggest that you obtain information regarding the "Soveran," as this is resilient, porous, permanent and independent of all kinds of weather.

Names of Plants.—*A. C. C.* and *D. S.*—We regret we are unable to name florists' varieties of flowers.—*A. E. Y.* (Red) Haemanthus Katherinae; (white) Tabernaemontana coronaria.—*G. C.* Akebia quinata.—*F. E. S.* 1, Smilax (send when in flower); 2, probably Teucrium Chamaedrys (send when in flower); 3, send when in flower; 4, specimen too small, send when in flower; 5, probably Veronica Teucrium (send when in flower); 6, Anchusa myosotidiflora; 7, Saxifraga cordifolia.—*A. T.* 1, Scilla bifolia; 2, Brodiaea uniflora; 3, Anchusa myosotidiflora.—*G.* Coronilla glauca; 2, Berberis Hookeri var. latifolia; 3, Rhododendron (Azalea) amoenum; 4, Prunus serrulata var. Hisakura; 5, Magnolia Soulangeana; 6, Diervilla florida.—*K. Y.* 1, Asparagus acutifolius; 2, A. falcatus; 3, A. myriocladus (?)—*F. M. B.* 1, Eriobotrya japonica; 2, Photinia serrulata; 3, Raphiolepis japonica.

Peaches and Salt Water.—*A. H. R.* It is very difficult to state what amount of damage would be caused by the salt penetrating into the greenhouse tank, without inspecting the vines and plants under cultivation. Judging from the foliage, the Peaches appear to be suffering from mildew, and the only way to prevent other fruits becoming affected is to spray the trees with a mildew wash; there are several proprietary washes on the market, and they should be used strictly in accordance with the directions given with them.

Preparing Cheshunt Compound.—*F. W. R.* Cheshunt compound cannot be secured ready prepared, but may be made as follows:—Mix two parts, by weight, of powdered copper sulphate with eleven parts of finely crushed, fresh ammonium carbonate, and store it in a tightly-corked glass or stone jar for twenty-four hours. Dissolve one ounce of this dry mixture in a little hot water, and add it to two gallons of cold water. It should be used immediately after being prepared (only sufficient for immediate requirements should be mixed) and should not be put into iron, tin or zinc containers, as it corrodes them and loses its strength. This fungicide originated at the Cheshunt Experimental Station, hence its name.

Postal Instruction on Draughtsmanship.—*J. B.* We do not know anyone who conducts a correspondence course in draughtsmanship, but suggest that you apply to your County Horticultural Instructor, who may, perhaps, know of someone who would help you.

Communications Received.—D. C.—J. M.—G. T.—W. T.—J. P.—D. S.—G. D.—H. F. L.

TRADE NOTES.

At his annual exhibition of bulbous flowers, at Highfield Bulb Farm, in Ayrshire, on April 22, Mr. Montgomery Crawford staged over 200 vases of the newer Daffodils, including two seedlings of his own raising named Highfield Earl and Highfield Prince. They belong to the giant Trumpet section, and the latter is a beautiful, bold flower with a well-formed perianth and large, frilled trumpet. Other prominent varieties were two Leedsii novelties, Elegance and Hey Day; Orange Beauty, Dragoon, Advance Guard, of the King Alfred type; Pride of the Market, Stella Tydd Pratt, Souvenir, Volenti, Fortune, Rubina and the Poetaz Narcissus, Scarlet Gem. Two examples of the double Daffodil Carnation emphasised the high colour obtained by the application of potash. The visitors afterwards inspected the area of land devoted to the culture of Daffodils, Tulips, Hyacinths, Irises and Gladioli, and the proceeds obtained from the sale of flowers were handed over to the local nursing association.

During recent years, the making of miniature gardens, in suitable receptacles, for the embellishment of the house has developed into quite a small industry, and a splendid collection of such gardens was viewed recently at the establishment of April Showers, Ltd., 54, South Molton Street, W.1. In this instance the receptacles are ornamental bowls of real value—Wedgwood, Doulton, Minton, and Denby ware, and the plants with which they are furnished are dwarf Conifers of various sorts, Cacti and other Succulents, Japanese Maples and Euonymus; use is also made of the quaint Corokia Cotoneaster, and the "mature" gardens are disposed of at prices ranging from ten shillings upwards.

SUPPLEMENT PLATE.
Rock Garden at Rowallane.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 54·6°.

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, May 15, 10 a.m. (Greenwich time). Bar. 29·9. Temp. 54°. Weather Cloudy.

The Destructive Ivy.

SIR MARTIN CONWAY has recently, in the columns of *The Times* (May 11), drawn up a spirited indictment against Ivy as a destroyer of castles and other ancient buildings. We fear that the indictment is well-founded, and recommend that everyone who has ancient buildings of any beauty or interest under his charge should take the necessary steps to repel the invader while there is yet time. Sir Martin's description of the insidious ways of Ivy as a taker and destroyer of castles is so graphic as almost to make our flesh creep. The siege is as subtle and more sustained than that of armies. It mines, it batters and it escalades. Below, at ground level, it thrusts itself between the stones until, as at Allington, near Maidstone—the castle to which Sir Martin's genius has done such wonders of restoration—burrows three feet deep have been found. While mining goes on below, the foe escalades the walls, and having reached the top, sends its roots in between the stones until they are so loosened that they fall. No less interesting are Sir Martin Conway's suggestions that Ivy has developed these vandal habits only in recent years. He has ascertained from old prints there was no Ivy on the walls of Allington Castle before 1800. Yet by 1900, that is, a few years before Sir Martin began the work of restoration, Allington Castle was entirely clad in Ivy, which stood out in some places so much as six feet from the wall. Sir Martin suggests that the besieger approached the battlements under cover of the neighbouring woods. When the Hederaceous army had filled the woods, covering the ground, and had, by exercise on Oaks and other trees, become perfect in the methods of attack, it advanced to the foot of the castle walls. Slowly and surely by mine and by assault, it was wrecking the Castle until Sir Martin, in true knightly fashion, bade it pause. Like all victorious men, Sir Martin finds his conquest easy, all that need be done is to sever the Ivy in two places near the ground level and tear away the intervening fragment. Sir Martin makes the interesting suggestion that it is only in the past century or so that Ivy has learned the trade of siege. As already cited, Allington was Ivy-free a century or so ago. Yet the castle, like a hundred others, had been open to attack ever since the days of Cromwell, if not before. Who turned the wheels of her chariots? Sir Martin conjectures that the castles remained immune from the attack of Ivy because the plant was not yet practised in the arts of attack. Another conjecture is possible. Invisible pioneers preceding the Ivy sappers and miners needs must work long and secretly before the latter may approach and mine. These are the Lichens, plants often so minute as to escape notice, which possess to an extraordinary degree the power of sending deep down into stone and mortar dissolving threads which prepare the way for the entry of the grosser and more brutal Ivy roots. It may well be that this first siege, unnoticed yet decisive, laid the castles of England open to the mass attack by the Ivy, and that in the crumbling state to which Lichens, aided by frost and weather, had reduced the mortar, the Ivy was able to claim victory in the comparatively brief space of one hundred years. Sir Martin may, however, object that we have no right to dismiss Ivy from the role of chief villain, and may point to his observations of the invasion of Allington woods by Ivy. To this we would reply that much woodland became more or less derelict in the nineteenth century, and that this neglect of coppicing and woodland management might be quite sufficient to let in Ivy; in other words, Ivy has not learned new tricks. It always knew them, but only in the neglect of woodland and in the desertion of castles has it found its opportunity of overrunning the one and overthrowing the other.

Rowallane.—We have on several occasions had the pleasure of publishing illustrations of portions of Mr. H. Armytage Moore's fascinating garden at Rowallane, Co. Down, particularly in our issue of September 15, 1928, when the main features of the garden were described. We now present our readers with a Supplement Plate showing part of the extensive rock garden at Rowallane.

Flowering Crabs at Kew.—A number of the ornamental Crabs rank high among the most beautiful of flowering trees of moderate size. Many of them are also handsome and attractive in fruit during the autumn. They are very well represented at Kew, considerable numbers being planted on the lawns and in the shrubbery borders. At the south end of the Temperate House, near the Chinese Pagoda, where the Pyrus family occupies a considerable area in the Rosaceae collection the Crabs and Pears are flowering in unsurpassed profusion, the branches of many of the trees being wreathed in flowers from end to end. The clusters of blossoms vary in the different species, varieties and hybrids, from pure white to rich pink, and on to purplish-red and claret. Not the least attractive are several trees of the common wild Pear, Pyrus communis, one tree in particular with its graceful, semi-pendent habit and wealth of white blossoms suggesting a snow-capped pyramid. On a mound near the Palm House a large group of the Japanese Crab, Pyrus floribunda, with pink-tinted blossoms, and the variety atrosanguinea, with rosy-red flowers, forms a dense tangle of branches, the wide-spreading, small trees or large bushes being covered with blossoms. On either side of the Palm House several large trees of the Siberian Crab, P. baccata, form beautiful specimens, thirty to forty feet high, covered with pink-tinted white blossoms. Several trees of Pyrus purpurea on the lawns are very striking in colour. In a hybrid raised in France between P. floribunda and P. Niedzwetzkyana, the young foliage is red and the flowers glowing purplish-red. Two other hybrids obtaining their remarkably distinct purplish-red colouring from the attractive Russian Crab, P. Niedzwetzkyana, are P. Eleyi and P. aldenhamensis, both of which are valuable additions to the family of flowering Crabs. P. spectabilis flore pleno is a semi-double form of a North China Crab, with an abundance of blossoms, rich rose in bud, and pale pink when fully open. A tree of the variety Kaido is very prominent in the Pyrus collection, the rich rosy-pink blossoms being very attractive. P. Scheideckeri is another hybrid, notably free-flowering, with pale rose blooms that fade to white with age.

Bury Hill Gardens, Dorking.—By kind permission of Colonel R. W. Barclay, the gardens at Bury Hill, Dorking, will be open to the public on May 25 and also on June 8, in aid of the Queen's Institute of District Nursing. The gardens are noted for the fine specimen Conifers they contain; Rhododendrons and Azaleas are also extensively grown.

Kew Guild Annual Meeting and Dinner.—The Annual General Meeting and Dinner of members of the Kew Guild will be held at the Clarendon Restaurant, the Broadway, Hammersmith, W. 6, on May 23. Mr. A. W. Hales, A.L.S., will preside at the Annual Meeting at 6.30 p.m., and an hour later, Mr. J. Coutts, the President for 1929-30, will preside over the dinner.

Chelsea Show.—The general lay-out of the Royal Horticultural Society's Spring Show in the grounds of the Royal Hospital, Chelsea—May 22, 23 and 24—will be similar to that of 1928, with some modifications. The size of the large marquee has been increased by 3,500 square feet, and an additional tent erected to accommodate Mrs. A. Sharman Hoyt's exhibit of Californian desert plants. The educational and scientific section will include exhibits from the R.H.S. Gardens and Laboratory, Wisley; the Royal Botanic Gardens, Kew; the Royal Botanic Garden, Edinburgh; the East Malling Research Station; the Cheshunt Experimental Station; the Rothamsted Experimental Station; and the Seale-Hayne Agricultural College. The catering is in the hands of Messrs. J. Lyons and Co., who will have two large refreshment tents in the Ranelagh Gardens. The National Tulip Society will hold its exhibition on the second day of the show in a marquee near the tents devoted to Roses and Orchids.

British Carnation Society's Outing.—On April 11, about eighty members and friends of the British Carnation Society visited Messrs. C. Englemann's Carnation establishment at Saffron Walden, and spent a very pleasant day inspecting Mr. Englemann's Carnation novelties. The majority of the party travelled down in special restaurant coaches on the 11.50 a.m. train from Liverpool Street Station, the others, about twenty in number, making the journey by road. Among the novelties not yet in commerce, the large-flowered, crimson-coloured Wanda met with general approval, while other choice sorts which were much admired included

Maggie, Dainty, and the American variety, Betty Lou. After inspecting the Carnations, the party visited the sections devoted to Roses and Orchids, both of which are grown extensively at Saffron Walden.

The Bulb Industry in Holland.—Probably no one is more able to write of the bulb industry of Holland than Mr. Ernest H. Krelage, whose long association with the bulb trade, and position as President of the General Dutch Bulb-growers' Society, enables him to write with authority, as he has done in *The Financial and Economic Review* (Amsterdam). This contribution, now reprinted, has been sent us by the author, who tells a very interesting story of the origin of the industry, its organisation and development. It appears that there were about 300 hectares under bulbs in 1850, and now there are over 6,000 hectares, with Haarlem as the centre of the industry. Mr. Krelage deals with improved methods of cultivation and of combating diseases, and shows that Great Britain is Holland's chief customer for bulbs, the exports to this country in 1901 amounting to 4,000,000 kilos, and in 1928 to nearly 16,000,000 kilos; in the latter year the exports to America were nearly 11,000,000 kilos; to Germany, Austria, etc. (German group), 8,000,000; to France and Belgium, etc. (French group), about 1,500,000; and to Sweden and Norway (Swedish group), 6,000,000 kilos. Mr. Krelage has a tilt at America—‘ Restrictive measures do not primarily affect the bulb industry so much as the consumers in the country of destination. The consumers must either pay abnormally high prices for bulbs, or they must be satisfied with the meagre choice of a few other kinds of flowers grown and sold at very high prices in the country prohibiting bulb importation. It is a cause of constant surprise that the consumers in countries which have introduced these restrictive or prohibitive regulations do not oppose them more strongly." Bulbs constitute one of the twelve most important articles of Dutch export, and the export figure for 1928 was 43,000,000 kilos, valued at about the same number of guilders. We admire Mr. Krelage's patriotism, and his "survey" of the Dutch Bulb Industry, but our own patriotism will not permit us to allow that ‘in other countries the culture of bulbs is either impossible or of very limited importance, since only very few kinds of bulbs are grown outside Holland." Darwin Tulip and Daffodil bulbs can be grown as well in this country as in Holland; indeed, certain Dutch growers have settled down in districts where our own growers have long since established successful bulb farms from which, quite frequently, they have exported high grade stocks or special varieties to Holland. Moreover, we take high place as raisers of Daffodils, as evidenced by the crowd of Dutchmen who come over to the London and Birmingham Daffodil Shows, eager to obtain the best new varieties.

The late Mr. Frank Evans.—At a meeting of St. Paul's Church Sunday School teachers at Birkenshaw, it was unanimously decided that a memorial should be placed in the church recording the valued and life-long service of the late Mr. Frank Evans, who for many years was gardener to the Oddy family at Moorlands House, Birkenshaw.

Bakewell Flower Show.—Already the annual exhibition held at Bakewell has achieved fame in and beyond the Midlands. It is held in a delightful district, close to the famous Chatsworth Gardens. The local Committee, with Mr. W. Roland Burke as Chairman, has prepared an attractive schedule of classes for the Show, to be held on August 8. A first prize of £12, with other awards of £7, £4 and £3, respectively, are offered for a collection of hardy perennials arranged on a space of thirty feet by ten feet; £10 is the first prize for a display of Sweet Peas arranged for effect on a space twelve feet by five feet, while £20 is the first prize for a decorated table of fruits, and there is a similarly handsome first prize for a collection of vegetables. Sweet Peas, garden flowers of many kinds, plants, and fruits and vegetables are provided for, and one section of the schedule is arranged to attract cottagers and allotment holders. Exhibits must be staged by 9.30 a.m. at latest, and "no extra time will be allowed under any circumstances." Schedules may be obtained from Mr. A. D. Coates, Hon. Secretary, Estate Office, Chatsworth, Bakewell, or from Mr. J. G. Weston, of Chatsworth Gardens, who is the Show Manager for the sections for trade displays and open classes.

Mr. T. W. Taylor.—A Gloucestershire man by birth, Mr. T. W. Taylor commenced his gardening career under his father at the Manor House, Ham, Surrey. At the end of two years he left to go as improver in the gardens at Offchurch Bury, Leamington, where he gained further experience both under glass and outside. His next move was to Barcote, Faringdon, a place which at that time was renowned for its rich collection of Orchids and stove and greenhouse plants. Leaving Barcote at the end of two years, he spent a short period in the Chelsea nursery of Messrs. James Veitch and Sons, and from there he obtained a position as first journeyman at Heythrop Park, Chipping Norton. After serving two years in the plant houses, he was promoted to fruit foreman, a position in which he had entire charge of a large range of fruit houses, as well as the hardy fruits. He remained at Heythrop for four years, when, anxious to gain further experience, he turned his attention to public gardening, and entered the Royal Botanic Gardens, Kew, in May, 1902. After serving one year as a student gardener in the Tropical Department, he was promoted to the position of sub-foreman of the Temperate House pits, but in less than a year he was back in the Tropical Department as sub-foreman of the propagating section. In May, 1906, he was promoted to foreman of the Temperate House, a position he held until September, 1914, when he was transferred to the entire charge of the Tropical Department. In 1922 the foremen at Kew were raised to the status of Assistant Curators. Last year, Mr. Taylor made an extensive tour in Ceylon, Malaya and Java for the purpose of studying tropical vegetation growing under natural conditions, and to visit the Botanic Gardens in those countries. On May 20, Mr. W. J. Bean ends his long and able career at Kew, and on the following day Mr. T. W. Taylor succeeds Mr. Bean as Curator of the world-famous Kew Gardens.

MR. T. W. TAYLOR.

Botanical Tour in Cyprus.—A very interesting account of a botanical tour he recently made in Cyprus was given to the Linnean Society by Dr. G. Claridge Druce, F.R.S., on April 18. Dr. Druce pointed out that the botanical history of Cyprus is a long one. Theophrastus mentions some of its products, Dioscorides alludes to its Origanum oil, and Drummond, in 1754, was the first to record a definite endemic species, Quercus alnifolia; a second, Onosma fruticosum, was found by Labillardière in February, 1787; Putoria and the Cedrus had also thus early been noted. Its true scientific exploration was begun by Sibthorp in 1787, accompanied by his artist, Bauer, the discoverer of Pinguicula crystallina. Three of his original paintings of the island were shown—Monte Croce, 80 (Stavrovuni); the Monastery, 81; and Ipsora, 82; they were five weeks on the island, and noted 313 species, many of them being new to science. A few scattered notes were made between this date and 1831, when Aucher Eloy added many plants. The new species were published chiefly by Boissier. T. Kotschy visited the island three times between 1840 and 1862 and brought up the number of species to 1050, of which about 90 are cultivated, but there are at least 800 definite species in his list. Gaudrey, Hooker, Hanbury, Haussknecht, J. Ball, Sir Samuel Butler, Sintenis and Rigo, W. Barbey, T. Pichler, E. Deschamps, G. E. Post, E. Hartman, and others, have added to the knowledge of the flora. Mr. A. Lascelles (now Sir Alfred), when he was Judge there, and his sister, Miss Lascelles, made considerable collections in 1900–2; these, with Miss Samson's plants are at Kew. The list contains about forty-six additional species. The author climbed Chionistra, Hag Hilarion, Pentadactylos (for some distance), and searched the high ground at Platres, Pissuri, Prodromo, Kikkou, Agros, etc.; also the salt-marshes at Larnaca and Limassol, but the season was not forward enough for either the mountains or the marshes; also the area around Paphos, Morphou, Myrtru Lapithos, Kyrenia, Salamis, Nikosia, Kythraea, Famagusta, etc. He succeeded in verifying Sibthorp's records (hitherto not refound) of Cheilanthes fragrans—in two localities—Camelina, and Linaria Cymbalaria, which is really L. longipes. He verified Kotschy's unlocalised record of Silene Behen and Miss Samson's of Carduus pycnocephalus. One of the most interesting additions was that of Lamprothamnium papulosum, J. Groves, a great extension in the north-east.

Prevention of Frost Damage.—A New Zealand reader of *The Gardeners' Chronicle* has kindly sent us an extract from the *Auckland Weekly News*, which tells of a method adopted by an Otiake fruit-grower to prevent damage to his trees by frosts. The extract reads as follows:—"For years the orchardists of the South Island have suffered heavy losses through the destructive influence of frosts. Various remedies have been tried, but with only moderate success. Mr. Harris, an orchardist at Otiake, near Oamaru, says he has discovered a method of fighting the frosts which will be both economical and effective. It consists of two blocks of Oamaru white stone (Bath stone) excavated in the centre. In these excavations inflammable liquid is poured. This penetrates the stone, and when a match is applied the stone rapidly becomes red-hot, and remains so for a period of almost four hours. The stones are placed beneath fruit trees before being heated, and are covered with kerosene tins."

Popularising the Chrysanthemum.—The Belgian Chrysanthemum Society arranged a public lecture on the growing of Chrysanthemums at the Brussels Botanic Garden, on May 5, at 11 a.m., and in order to secure a large attendance, rooted cuttings were distributed to those present. The lecture was given by M. Fr. Roekens, the Secretary of the Society.

Salford Flower Show.—Judging by the schedule recently received, the Salford Flower Show—an annual event, established in 1882, and organised by the Salford Parks Entertainments Sub-Committee—is this year, as in previous years, likely to prove a very popular horticultural event; it is to be held on September 3, 4 and 5, at Buile Hill Park, Salford. There are 291 classes for horticultural subjects—flowers, fruits and vegetables, and window plants; also cottage garden and window-box competitions, together with special sections for poultry and pigeons. The prize-list is a very attractive one, and many fine trophies are offered, especially in the open classes for groups of various flowering plants—herbaceous, Dahlias, Roses, Gladioli, Orchids, and Pansies and Violas.

Juvenile Gardeners at Guildford.—The Guildford Gardeners' Association encourages "the gardening habit" among the school children of the town, and in previous years has distributed plants which the more successful growers exhibit at the summer show. If we remember rightly, Antirrhinums and Violas have been distributed in other years; the youngsters are to try their skill with Fuchsias this year, and 1,558 plants were applied for.

North-east Coast Exhibition Flower Shows.—In our reference to the North-east Coast Exhibition (p. 341), we stated that applications for schedules for the flower show could be obtained from Miss A. M. Kelly. We understand, however, that although the whole of the gardens have been and are under the direction of Miss Kelly, the Flower Shows come under a pecial committee, with Mr. Herbert Shaw as Chairman, and Mr. J. Anderson and Mr. G. W. Paterson as Hon. Secretaries, to whom communications should be addressed at 20, Grainger Street, Newcastle-on-Tyne. The show dates are July 4 to 6, and September 5 to 7.

The late Sir Wm. Thiselton Dyer.—A lengthy, intimate and interesting account of the life and work of the late Sir William Thiselton Dyer, together with a characteristic portrait, appears in the current issue of the *Kew Bulletin* (No. 3, 1929). In the same issue, Messrs. Smith and Hubbard continue "Notes on African Grasses," and refer to an interesting experiment made with Puccinella angusta, a species that appears likely to be of great service for sheep grazing in South Africa, particularly on land saturated with saline salts. Mr. T. A. Sprague discusses the name of the Sugar Maple, and contends that Acer saccharum must stand and not A. saccharinum.

Manchester Parks Departments' Journal.—The fifth issue of the *Journal* of the Manchester Parks and Cemeteries Departments' Society has reached us, and although it is of interest chiefly to those who are, or have been, employed under Mr. W. W. Pettigrew, it is, nevertheless, of wide interest, particularly to those engaged in public parks. Mr. M. Morgan discusses and emphasises the "Importance of Detail," while Mr. G. Haig writes pleasingly on "The Value of Botanical Knowledge" to "the keen student of horticulture." Some of the features of Fog Lane Park are described by Mr. R. T. Pierce, and those of Wythenshawe Park by Mr. L. E. Morgan, who was recently appointed Superintendent of the Stockport parks. The activities of the Society are reported and a syllabus of lectures to be given during the 1929-30 session is included. Last year the members visited Edinburgh; this year they propose to visit Windsor Castle Gardens, Frogmore, Eton, Cumberland Lodge, Windsor Park and Windsor Castle; they will leave Manchester at midnight on August 23, by saloon train, breakfast on the journey, and arrive at Windsor at 6 a.m. Mr. G. Cule is the Secretary of the Society. A few copies of the *Journal* are available to non-members, and may be obtained post free for 1s. 2d. from the Hon. Treasurer, Mr. J. G. Slater, Guildhall Chambers, Lloyd Street, Albert Square, Manchester.

Seventieth Birthday of "Cactus" Haage.—On April 8 this year, Ferdinand Haage, the proprietor of the Erfurt Cactus-growing business conducted as F. A. Haage, junior, celebrated his seventieth birthday. The firm is over one hundred years old, but when the present proprietor took it over, it was of small dimensions, and it was he who worked it up to its present world-wide importance—an importance difficult to realise in this country, where Cacti are not very popular. In Germany, however, where the majority of town dwellers have no gardens at all, and are obliged to meet their taste for gardening by growing plants in pots indoors, the cultivation of Cacti has attained to a quite remarkable popularity. In these circumstances, Ferdinand Haage has become known not merely as a specialist in, and supplier of, Cacti, but as the guide, philosopher and friend of all Cactus growers, from the big trade customer down to the humblest beginner, consequently he is known as "Cactus" Haage and "Uncle Ferdinand" all over Germany. Still strong and vigorous, he may fairly look forward to many years of active life and continued enjoyment of the popularity and affection he has done so much to deserve.

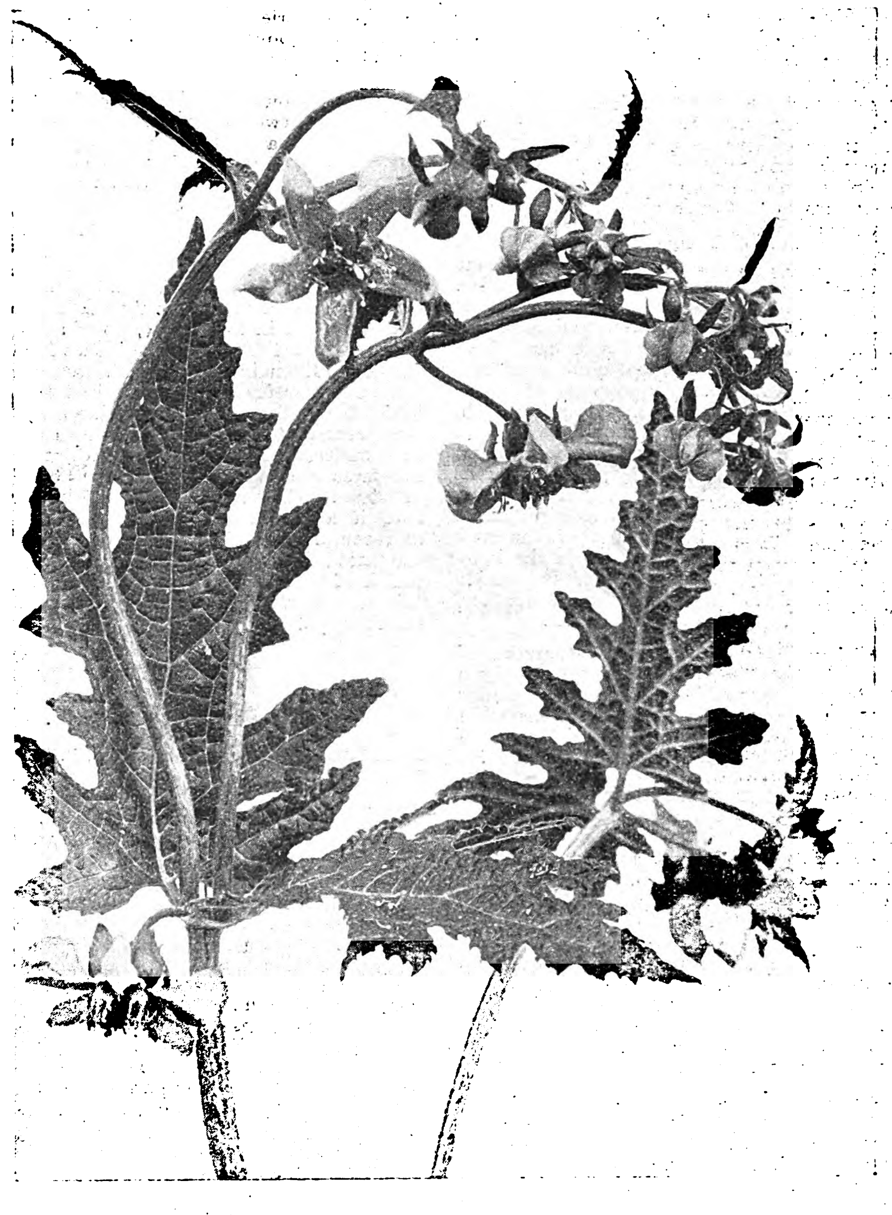

FIG. 178.—LOASA ACANTHIFOLIA.

R.H.S. Award of Merit, May 7. Flowers orange. Shown by Mr. Clarence Elliott. (see p. 352).

Appointments for the Ensuing Week.—Wednesday, May 22: Royal Horticultural Society's Chelsea Show (three days); Gardeners' Club Annual Dinner, St. Ermin's Hotel, Westminster; Newcastle and District Horticultural Society's meeting; Bath and West of England Show. Thursday, May 23: Kew Guild Annual Meeting and Dinner, Clarendon Restaurant, Hammersmith. Saturday, May 25: Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Horticultural Society's Show at Chiswick.*—Nothing could be more brilliant than the exhibition of flowers and fruit at Chiswick last Saturday. It was a beautiful day, and four or five thousand visitors would have been present had not the presence of the Queen at Woolwich carried off all except 1,764. To those who did attend, the exhibitors offered a real treat. Such Roses and such Azaleas have rarely been seen; and when it is stated that those two classes nearly filled the largest tent on the ground, it will be understood that that part of the exhibition must have been a terrestrial paradise. The Orchids were abundant and excellent, notwithstanding the absence of Mrs. Lawrence and Mr. Rucker; and the greenhouse plants, especially those from Lady Antrobus, were models of cultivation. Let us hope that huge unwieldy plants will be seen no more; for they cost so much for carriage, and are in all respects so inferior to beautiful specimens like those of Mr. Green, that exhibitors will surely now discover that it is entirely contrary to their interest to persevere in their production. The new arrangements for rewarding fruit have evidently found favour among gardeners; for no May show in our remembrance has produced so great an abundance of such remarkable excellence. Novelties among plants were few. The most striking was a new salmon coloured Indian Rhododendron, in the way of javanicum, produced by Messrs. Veitch, and a very fine thing. The next was the woolly-stemmed Cypripedium villosum, from Borneo, from the same great importers; and third in merit was a species of Hederoma called by the ambitious title of Genetyllis tulipifera, of which a detailed account appears in another column. *Gard. Chron., May* 20, 1854.

Publications Received.—*Nature in Wood and Forest*, by W. Percival Westell; pp. 119, illustrated. The Sheldon Press, Northumberland Avenue, W.C.2; price 2s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Brazilian Miltonias.—Many of these Miltonias, such as M. spectabilis and its varieties, together with many supposed natural hybrids—M. Bluntii, M. Lamarckeana, M. Peetersiana and others—which generally produce their beautifully-coloured flowers during the late summer and autumn months, are now commencing to grow, and new roots will develop along with the young growths, when any necessary repotting should be done. As these Orchids are mostly surface-rooting subjects, and prefer a wide root-run rather than a great depth of compost, shallow, well-drained pans should be used, while a suitable rooting medium consists of three parts Osmunda fibre and one part chopped Sphagnum-moss, well mixed together. This should be pressed moderately firmly about the roots, and water should be afforded carefully. These Orchids thrive when grown suspended in a light position in the intermediate house and shaded from strong, direct sunshine; they require cultural treatment similar to that afforded Cattleyas. Ample supplies of water will be needed when the plants are in full growth, while plenty of light and air should be allowed to reach the growths as they are nearing completion, so as to secure well-ripened growths which are essential for the production of flowers of good quality. Thrips are often troublesome and quickly damage the foliage of the new growths, and these should be kept in check by spraying with a weak solution of insecticide at regular intervals, and in favourable weather, during the spring and summer months.

Shading.—With the increased strength of sunshine it may become necessary to apply a very thin coating of Hall's distemper, or similar shading, on the glass of the cool houses, in conjunction with the blinds, especially where blinds of the light lath-roller type are used.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

The Mealy Plum Aphis.—The life history of the Mealy Plum Aphis (Hyalopterus pruni) is not very clear; at least, it is not definitely known what occurs between September and June. It is assumed that the winter and early spring stage is spent on riverside reeds and grasses, but so far, no eggs have been found. This aphis appears during June and July as winged females. Young are produced alive in great numbers on the Plum leaves which, for some extraordinary reason, do not curl, nor does the presence of the aphides interfere with the normal growth of the young shoot. Much grey meal is produced on the bodies of these insects, and this falls on to the leaves immediately below them. This meal, with a large amount of honey-dew secreted, makes the fruits and leaves filthy. This pest has a particular liking for the varieties Victoria and Pond's Seedling, possibly on account of their large, fleshy leaves. Remedial measures should be applied in the earlier stages, as the mealy covering is difficult to penetrate when the insects are present in large numbers.

The Plum-leaf-curling Aphis.—Another aphis of a similar nature, and equally destructive, is the Plum leaf-curling aphis (Aphis pruni). The life history of this is, in most respects, the same as that of the Cherry aphis. The aphides fly away to some unknown plants, probably grasses, and return in autumn, giving rise to sexual forms which produce the eggs. This pest attacks Plums and Damsons, and occasionally Apples and Peaches. The same remedial measures as for Cherry aphis—soft soap and nicotine—should be applied before the leaves commence to curl.

Apricots.—Trees on walls have set fruits well. They should be afforded much the same treatment as Peaches, except that only the superfluous and badly placed shoots should be removed, and the remainder stopped at the fourth or fifth leaf to form fruit spurs. Where extension of growth is desired, or bare places require furnishing, a selection of the best placed shoots may be laid in and made secure. The fruits should be thinned gradually, so that they are finally from four to eight inches apart, according to the variety. Thus, Oullins Early Peach, Moorpark, Shipley's and Powell's Late, all produce large fruits and will require the maximum amount of space, while Breda, Kaisha and Early Moorpark produce fruits medium to small in size, and will require only half the maximum distance. Frequent soakings with clear water, followed by applications of liquid manure and a mulching, will keep the trees in good health and vigorous during the summer months. The trees should be inspected frequently, and any shoots not required for extension should be stopped. Subsequent growths should be stopped at the first or second leaf.

Transplanted Fruit Trees and Moisture.—The rainfall for the first four months of the year has been abnormally low, if not a record. In January we registered only 1·23 inch, in February ·73, in March ·01, and in April 1·03, making a total of only three inches for the four months. Even in 1921, which was considered a record year for drought, we had 4·35 inches in the first four months. There is a grave danger that trees that were planted late in the season may suffer from this prolonged drought unless measures are taken to counteract the lack of moisture. The surface soil should be broken up and, if a mulch of manure was not applied as recommended at the time of planting, give the trees a thorough soaking and apply a good mulch of decayed manure, several inches in thickness, to well beyond the outward extent of the root system.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Bedding Plants.—Commence to harden-off all bedding plants that are sufficiently advanced, by removing them from the pits to cold frames. So many tender plants are severely checked during this process that it takes them a considerable time to recover. The weather is often treacherous during the first half of May, therefore every precaution should be taken to guard against too low a temperature by covering the frames with protecting material during the night. As the plants become used to their new quarters, they should be gradually inured to outside conditions, air being admitted freely on every possible occasion. Pentstemons, Calceolarias, and other half-hardy plants that were rooted in frames, may now be planted in their flowering quarters if the ground is vacant. Lobelia cardinalis and the many new Lobelia hybrids that have been introduced during recent years may, if they have been wintered in a cold frame, also be planted out. These plants revel in rich, moist soil, and when preparing positions for them apply a very generous dressing of leaf-mould to the soil. Plants of early-flowering Chrysanthemums that were rooted in early spring and grown on in cold frames, may be planted out, provided they have been hardened off well. They are equally useful for filling beds or borders, or for supplying cut flowers during autumn. Allow sufficient room between the plants for development, according to the variety. For the bushy sorts, two feet will be none too much, and eighteen inches for those of more erect habit. Incidentally, these Chrysanthemums may be grown in nursery beds during the summer and transferred to the flower garden as they come into bloom. Chrysanthemums so treated show few signs of distress provided they are well watered, and each plant is cut round with a spade a few days before being transplanted.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Plums under Glass—The Plum trees which were started with the Cherries will now be behind the latter in fruit development. If the fruits are swelling freely, they should be well thinned with Grape scissors, retaining, preferably, those situated where there are most leaves. The earliest trees will have barely passed the stoning stage, therefore mulching, feeding and syringing must be continued for some time. Only soft water should be used, and then sufficient to wet the fruits completely, as if the fruits are only partly wetted their appearance will be like that of badly finished Grapes. Partial wetting or light spraying often spots the fruits, while liberal syringing leaves the " bloom" intact. Aphis should be kept in check by occasional fumigations.

Melons.—Although the weather has not been severe, incessant firing has been absolutely necessary during the very cold nights, especially if fermenting material has not played an important part in the maintenance of bottom-heat. In dry pits the syringe may, and should, be used freely, but the conditions most favourable to the growth of early Melons is a moist atmosphere secured from the fermentation of litter and leaves. If the bottom heat ranges from 80° to 85°, and the female flowers begin to open, syringing may practically cease, but sufficient fire heat should be employed to maintain a free circulation of air until the fruits are set. When the fruits have attained the size of hen's eggs, the final earthing up should be performed, early enough for the roots to permeate the fresh soil before the plants begin to feel the strain of cropping, and the amount of compost afforded should not be excessive. Where directions given previously have been carried out, feeding from this stage forward should be practised on a liberal scale, and the more frequent the change of diet, the better will be the progress of the plants, and the finer the fruits. Temperature by night should range at about 70°, and that by day from 80° to 85°, rising, through sun-heat, and as a result of a thorough syringing with tepid water, to 90° to 95° after closing. Culture after the fruits are thinned is very simple; preserve every premier leaf from injury, remove all useless spray, and pinch lateral growths at the first joint in advance of the fruit. Successional plants, now in various stages of growth, may be treated as advised in former calendars, except that the amount of heat may be increased considerably, especially on bright, sunny days, when air may be admitted. The minimum temperature need never fall below 70°; sudden changes of temperature must be avoided, and water which is colder than the atmosphere of the house should never be used indiscriminately. When in free growth the plants may be afforded liberal supplies of tepid water, but liquid stimulants should be reserved until the fruits commence swelling; top-dressings of strong loam, previously warmed, should be given as the roots appear on the soil surface.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Ixoras.—The Ixoras rank among the most beautiful of all stove plants, but, alas, they are rarely met with in these days. The conditions necessary to secure healthy and well-flowered specimens are, without doubt, a comparatively high temperature and abundance of atmospheric moisture during the growing season. The compost should be of an open nature, consisting of good fibrous loam and peat, with sharp sand and broken charcoal added. Pot them moderately firm, and afford light shading during the growing season, for if the young growths are exposed to brilliant sunshine they will suffer somewhat, although during the dull months of the year light is essential to their well being. Young plants that are being grown on may be potted at any time it is found necessary to do so. Propagation of Ixoras is readily effected by cuttings, taken so soon as large enough and inserted within the rim of a small pot, singly or otherwise, and placed under a bell-glass on a temperate hot-bed. Under such conditions, and provided they are shaded from sunshine, the cuttings will root quickly and, if subsequently given careful treatment, will form good plants the following year.

Hippeastrums.—As these plants pass out of flower they should receive every encouragement to produce strong, healthy foliage, for much will depend on the treatment meted out to them during the next few months as to their floral display next season. Plants that have been forced into flower in strong heat tend to produce weak foliage which, unless supported, is liable to fall over and break, with the result that good, stout bulbs are not obtained. The plants should be fed liberally with liquid manure and grown in a temperature ranging from 60° to 70°, but after the foliage has fully developed they may be transferred to a house having a lower temperature, and placed in a sunny position in order that the bulbs may be well ripened. Continue to afford water until the foliage shows signs that a rest is needed.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

New Zealand Spinach.—Seeds of this Spinach, which withstands dry conditions well, may now be sown. Sow the seeds in shallow drills eighteen inches apart, and when the seedlings are large enough to handle thin them to one-and-a-half foot to two feet apart for, when mature, they cover a large surface of ground, and will afford plenty of fresh leaves well on into the autumn.

Brussels Sprouts.—Plants from seeds sown early, and which were pricked out into boxes, will now be ready for transferring to their permanent quarters. The ground, which should have been prepared some time ago, should be levelled and made fairly firm, and the plants placed two-and-a-half feet apart in drills three feet apart. The drills should be six inches deep, and when removing the plants from the boxes, do so with a trowel, taking care to secure a good ball of soil with each. After planting, make the soil firm about each plant and water well. As the roots obtain a hold of the soil, loosen the surface soil with a Dutch hoe, at the same time filling in the planting drills.

Potatos.—If the planting of main-crop Potatos has not yet been finished, no time should be lost in doing so. Earlier Potatos should be earthed up so soon as their growths are sufficiently advanced.

Lettuces.—Another batch of Lettuce seedlings should be planted out. These may be planted along Celery ridges, for they will be ready for cutting by the time the soil is required for filling in the Celery trenches.

Celery.—The seedlings that were pricked out some time ago, and which are intended to produce an early supply, should now be ready for hardening off. So soon as hardened they may be planted out. Main-crop seedlings may be pricked out into frames and afforded close conditions for a few days, together with shade, after which, air may be admitted gradually in increasing quantity.

Tomatos.—So soon as the outdoor Tomato plants have been hardened off they may be planted out in suitable situations, such as in front of glasshouses, where there is always plenty of shelter and heat; stake each plant, and as growth advances, secure it to the stake.

Cardoons.—Seeds of Cardoons may be sown either in pots or in the trenches where they are to be grown. If sown in pots, growth will be a few weeks earlier than if the seeds are sown in the trenches in the open.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Thin Turnip seedlings so soon as they can be handled easily, and sow small batches at intervals for succession, as the roots soon get out of condition. Stump-rooted Carrots should also be sown at frequent intervals, thinly enough to dispense with the necessity of heavy thinning and consequent root disturbance. French and Runner Beans may now be sown in quantity, giving them the best possible soil and aspect. Broad Beans, to supply a late crop, may be sown in good, heavy, well-manured soil, if possible.

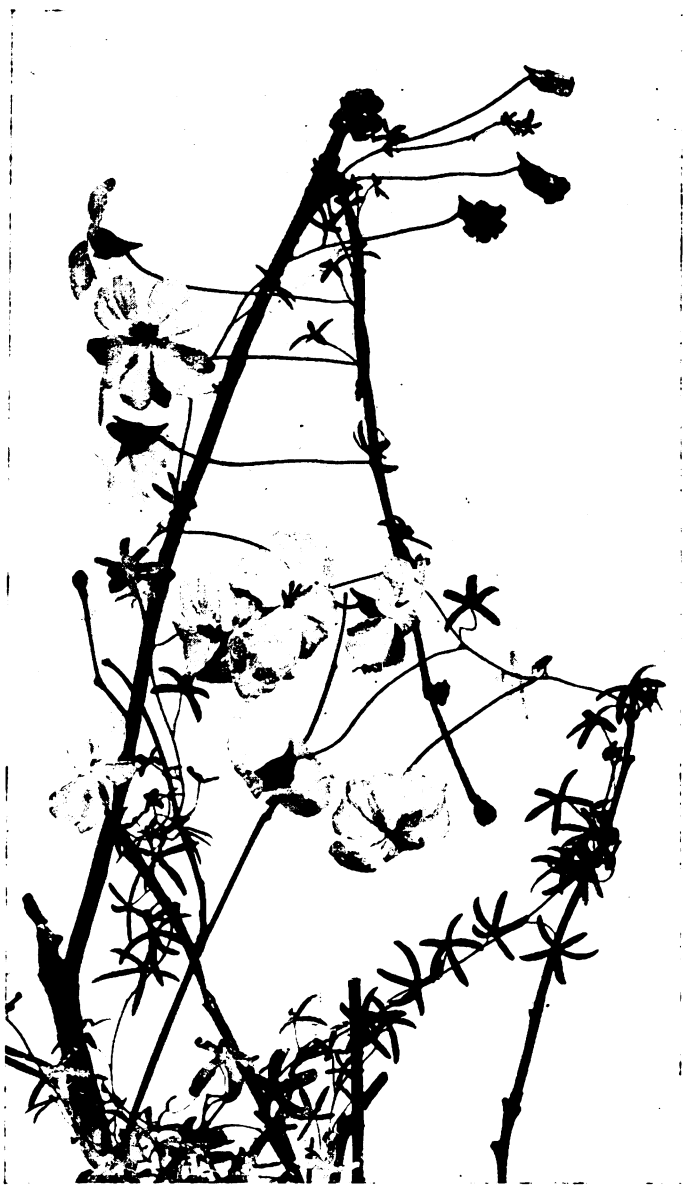

FIG. 179.—TROPAEOLUM AZUREUM.

R.H.S. Award of Merit, May 7. Flowers blue. Shown by Mr. Clarence Elliott. (See p. 352).

Chrysanthemums.—Late-flowering plants in pots should receive their second stopping if second crowns are required. As they break, decide upon the number of blooms required—twelve to fourteen—and remove all undersized shoots, retaining the strongest. If the soil for the final potting can be prepared now and allowed to sweeten until early June, much good will result. Most growers have their own favourite compost, but I venture to suggest one of loam, three parts; partly decayed manure, one part; partly decayed leaf-mould, one part; rough sand, one part; fine bone-meal, a quarter-part; charcoal and wood-ashes, one part; and soot, a five-inch potful to each barrow-load of compost. Only rough, fibrous loam should be used. Mix the compost well and place it in a heap in a rain-proof place, and turn it in a week or ten days' time.

Biennials and Perennials.—Wallflowers, Myosotis, Cheiranthus Allionii, Sweet Williams and other spring bedding plants, should be sown forthwith, either in boxes of light soil, or in a prepared bed in the open. Many perennials, such as Geums, Lychnis and Coreopsis, are prone to deteriorate in a few years, and fresh stocks should be raised annually if the best results are to be obtained. Polyanthuses, Aquilegias, Pyrethrums, etc., which were raised in heat and pricked off in boxes, should now have more room to develop, either by being planted in their permanent quarters, or in frames for autumn planting, as, if allowed to become starved and overcrowded, good results with them cannot be hoped for.

Greenhouse Annuals.—Cinerarias for early flowering, Primula obconica and P. malacoides, etc., should now be sown. Pans or pots of a light compost of about equal parts loam, leaf-mould and sand (a little less loam is, perhaps, desirable) should be prepared and the seeds sown thinly, watering them by placing the receptacles in a vessel of water so that the water may percolate up through the compost without flooding the surface. Place the receptacles in a closely-shaded frame until germination takes place, after which the seedlings should receive plenty of light, in a frame or house where the direct rays of the sun will not strike them.

WATSONIA ARDERNEI AND ORNITHOGALUM LACTEUM.

About ten years ago a kind friend of the Royal Horticultural Society sent from the Cape a case containing about two thousand corms of the beautiful white Watsonia Ardernei, and they were planted when they reached Wisley, in April, in the moist soil of the Azalea garden. There they grew and flowered among the Azaleas after the latter were past and before the coming of the autumn tints that make that part of the garden, with its frame of Austrian Pines, berried shrubs and Bamboos, so beautiful in September and October. Then, following the advice given in nearly all the books, the corms were lifted, dried off, and stored exactly like Gladioli, to be planted next spring. That winter nearly eighty per cent. of the corms died. It was clear that if this way of dealing with the plants were followed there would soon be none left, and we should be none the worse off if we left them to take their chance of the winter out-of-doors.

They were again planted, and again flowered, but they were left in, and every plant came through the winter safely, and most of them flowered. There they have been ever since. The clumps have increased, and every year their graceful spikes of clear white flowers appear in due season. The winter of 1927-8 was a very trying one, but although they were badly damaged in the foliage, they grew away well. The past winter has been worse, with long spells of frost down to –1°F. on the ground, yet again these plants of W. Ardernei are thrusting up the green leaves among the brown of last season.

Mr. Grove (p. 293) rightly states that Watsonia Ardernei generally dies out quickly, but these plants have not borne out the common experience. They have, with the unorthodox treatment, flourished and increased, and apparently they have the conditions that suit them. They have moist, deep, peaty soil, sometimes under water for days in winter, and never dry far down; undisturbed possession of the ground; and such shelter only from frost as the dead leaves of the past year give. It may be that here is the secret of growing the beautiful Watsonia Ardernei in this country.

Another South African bulb, Ornithogalum lacteum, the flowers of which are probably more familiar than the plants, for they are frequently sent from the Cape, with the native Cape name of "Chinkerinchee," packed in card boxes, and remain fresh in water for weeks after they are unpacked, has come through two or three winters without serious damage, and is now growing well. This, however, is in a totally different situation under a west wall, where it has all the afternoon sun, and where it is, on the whole, very dry and well-drained. The plants have flowered there without disturbance two summers in succession, and would probably prove amenable in other gardens in places where Tigridias will survive. *Fred. J. Chittenden, R.H.S. Gardens, Wisley.*

BULB GARDEN.

FRITILLARIA KARADAGHENSIS.

With reference to Fritillaria karadaghensis (see *The Gardeners' Chronicle* of March 23, p. 221, Fig. 107), this species has been grown outside in Mr. A. C. Bartholomew's garden, at Reading, and although it did not flower, I think it has given proof of its hardiness. It is planted five inches to six inches deep, facing west, backed by a Portugal Laurel. Of the five bulbs potted, all flowered, with three flowers on each stem, and some of these are setting seeds.

Of other bulbs that came from Mr. Egger in October, 1928, and grown outside in the same position, there are Iris Bakeriana, Iris paradoxa var. violacea (flowered), I. reticulata var. Krelagei, Tulipa violacea var. pallida (flowered), and T. polychroma. Another Fritillaria from the same source flowered in a cold greenhouse; this was F. gibbosa, and the flower was flat and open, while another quite good bloom appeared at the end of February. *C. Cook, Reading.*

CROCUS TOMMASINIANUS.

This indestructible and beautiful Crocus painted the ground at Eastertide with wide-open cups of lavender, which wholly hide the slender, grass-like leaves from sight. In spite of its Eastern origin, the recent frosts have done no damage whatever to the corms, as, secure in their netted tunics, they defy cold and wet alike; one has only to plant a few corms of this Crocus in order to produce a good display, and then the plants increase steadily from year to year until the ground is full of small corms, each of which contributes its quota to the carpet of flowers. Sometimes the outer surface of the perianth is white in colour, although generally it is of a paler shade of the lavender-blue inside. The perianth tube is decorated with a white beard which varies from a distinct fringe in some cases to a merely papillose condition of the throat.

Any soil seems to suit this Crocus, although, of course, an open and well-drained position should be chosen in case stagnant conditions should prevail and possibly rot the corms. *Reginald Kaye, The Birch, Sharpthorne, Sussex.*

WOODLAND GARDEN.

EPIGAEA REPENS.

Many are the plants which, although common and free-growing in their own native countries, yet continually defy the gardener who would cultivate them, and such an one is the lovely Epigaea repens, which must prove a good "selling line" for those nurserymen who are fortunate enough to possess good stocks of it, for many are they who would woo this lovely, fragrant-flowered creeper, but few are successful with it. So that Epigaea repens, common enough in many parts of North America and known to many generations of English gardeners, continues to remain a rarity and a much-prized treasure, for seldom, indeed, are really good specimens of it met with in English gardens.

Why this is so is beyond explanation, although its resentment to disturbance would appear to have much to do with it, and it is not often that one can obtain really well-established specimens with which to make the attempt. And yet, in its native country, E. repens, known variously as the American Ground Ivy, Trailing Arbutus, Ground Laurel, Mayflower, etc.—a proof of its free distribution and popularity—flourishes abundantly, while its foliage is described as being valued for its medicinal properties. The late Reginald Farrer (*The English Rock Garden*) described how that, in America, E. repens is "often gathered up in its mats, and stored 'down cellar' in trays of leaf-mould so as to be brought up at Christmas to delight the house with its creeping masses of rather ample oval roughish green leaves, amid which in clusters shine the waxy stars of pearl-pale blossom, exhaling a steady breath of the most delicious fragrance."—A charming picture of it, but what a contrast to the poor, struggling specimens in which we take such pride, gloating over and admiring the few clusters of bloom, still, fortunately, deliciously fragrant, which may reward the many heart-burns for it.

E. repens, the best known species of the genus, and a member of the Natural Order Ericaceae, is one of the choicest of trailing, evergreen plants, and its pale, pink-tinted, waxy flowers, produced in small clusters during May, are among the most fragrant, their odour attracting attention to them from a considerable distance. It is naturally a shade-loving and woodland plant, being found often beneath Pine trees in America, so that a position in the woodland garden, beneath Coniferous trees or evergreen shrubs—Rhododendrons, Pieris or Camellias—would appear most likely to prove congenial to it, for it delights in fairly dense shade.

Another important factor is that it should be planted very firmly, while the chances of success with it will be increased if the soil contains plenty of coarse, sharp sand, and is of a peaty nature, supplemented with a good proportion of leaf-mould. Having been provided with these conditions, E. repens should be left to its own devices, undisturbed and, if possible, forgotten, until its fragrance of blossom calls attention to its presence.

In matters of propagation, E. repens presents the same difficulties, for seeds, when obtainable, do not germinate freely, and it heartily resents root-disturbance, therefore division is impracticable. Propagation by cuttings, rooted in sand in late summer, although difficult, gives the best results, provided careful after-treatment is afforded. *M. W.*

ALPINE GARDEN.

ANDROSACE SEMPERVIVOIDES.

In past years, when alpine plant growers were few, the cultivation of an Androsace with success was regarded as a feat of cultural skill, and he who succeeded for the first time in the successful cultivation of one or two of these gems was considered to have achieved the task of passing the *pons asinorum*, and generally prided himself upon it. Now, however, there are many successful cultivators of these exquisite plants, but it is well to learn of the most amenable species and what they require.

One of the most charming of all is now in bloom here; it has been established for two years in a moraine surfaced with whinstone chips with a full south-west exposure. It is growing in the lower part of the moraine, where a little old lime-rubble has been mixed with the staple compost of loam, sand and chips. Here A. sempervivoides is evidently happy and is very attractive, its leaves harmonising delightfully with the grey of the chips and the heads of rosy-pink flowers.

A. sempervivoides is widely distributed in the north-west Himalayas. It increases with freedom and forms lovely rosettes of oval, overlapping green leaves, while the rosy flowers are borne on stems from three to four inches high. *S. Arnott.*

ERIGERON LEIOMERUS.

The name Erigeron is usually associated, in the mind, with free-growing herbs, several of which, especially the newer, amply-flowered hybrids, are indispensable for the herbaceous border, the dwarfer kinds being useful for providing massed colour effects on the rock garden. But there is one species, namely, Erigeron leiomerus, which is not a rampant grower, nor is it by any means among the easiest of plants to cultivate successfully, and yet it possesses such charm and daintiness as to rank among the choicest of rock garden plants.

E. leiomerus hails from America—from the Alps of Utah, etc.—and in this country requires moraine treatment or, at least, an especially favoured position in perfectly drained, gritty, and light, loamy soil; in any case, it is happiest and most likely to survive our wet winters—my plant in the open has only just managed to scrape through the last, and is looking rather sorry for itself at present—if provided with a good layer of clean granite chips as a surface covering to the soil around it. It is an admirable subject for culture in the alpine house, where it is safest, provided it is treated with the care it deserves, and it also responds well to culture in a stone trough in association with other alpine pygmies.

For E. leiomerus is of dwarf stature, but forms a close little tuft of spoon-shaped, bright green leaves, and from among these, in late May and June, arise numerous, slender stems three or, at the most, four inches high, each bearing a lovely, solitary, Daisy-flower of pale but clear, lavender-blue colouring, singularly attractive and produced, for so small and aristocratic a plant, with considerable freedom. *Kent.*

THE NOBLEST JAPANESE CHRYSANTHEMUM.

The raising and appreciation of new varieties of the Chrysanthemum have not ceased for more than a thousand years in our empire, where the sixteen-petalled Chrysanthemum is the crest of our royal family. C. morifolium and C. indicum, the original species of Chrysanthemum, are also growing naturally in middle and southern Japan, consequently some people consider the Chrysanthemum was also developed from the wild species in Japan—as it was in China. We consider that "The Chrysanthemum is the most unworldly of flowers," but beauty and loveliness are only appreciated in association with nobleness, so we have many "noble" sorts in new and old varieties. Among them Takamikura (The Imperial Throne) is regarded as the noblest Japanese Chrysanthemum yet raised (Fig. 180). This has been very rarely seen in flower; it was raised by Mr. I. Moyama, a well-known expert, in 1926, but only last year was it distributed and then only in limited numbers. The colour is white, tinted with soft green. The long, outer florets are somewhat drooping and curled at the tips. The incurved inner florets are raised up towards the centre in a not too dense cluster. When intensively cultivated it is not rare that the flower exceeds two feet in diameter; indeed, Takamikura is the largest flower as well as the noblest. This variety has very long stems, growing to a height of seven to eight feet. It is a gross feeder, but over-feeding causes an excessively raised centre, and the noble appearance is then lost. Although so long-stemmed, the leaves are retained until flowering time. Japanese Chrysanthemum growers exercise great care to retain the lower leaves, as they do not appreciate the flower only, but the whole plant, whether it is potted or planted in a bed.

By-the-way, the preparation of soil and the cultural methods followed in Japan are almost as varied as the number of Chrysanthemum enthusiasts. *K. Yashiroda, Tonosho-Kyoku, Kagawaken, Japan.*

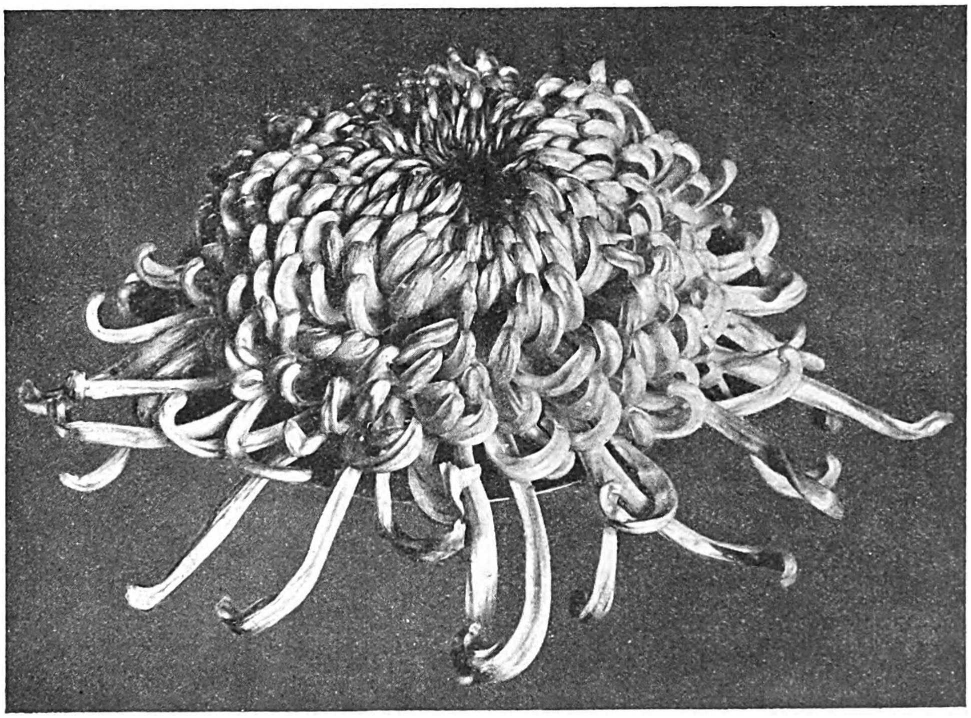

FIG. 180.—CHRYSANTHEMUM TAKAMIKURA.

INDOOR PLANTS.

HYBRID GESNERAS.

The ornamental foliage and numerous showy-coloured flowers of the Gesneras in cultivation to-day render them among the most useful subjects for house decoration during the autumn and winter months. By starting them into growth in successional batches they may be had in flower over a period of several months, and they are particularly pleasing during late autumn when house decoration usually means a continuity of Chrysanthemums.

Assuming that one is in possession of a number of the catkin-like corms, they may be started into growth now, in boxes of leaf-mould and sand, in a stove temperature, after the manner of Gloxinias and Begonias. Water sparingly until growth commences, and when the first pair of leaves is well developed, pot them into three-inch pots, either one in a pot for flowering in five or six-inch pots, or three in a pot to form large specimens for flowering in seven or even eight-inch pots—the latter method is not advisable unless distinct colours can be kept together in one pot.

The compost for this potting should consist of equal parts fibrous loam, peat and leaf-mould, adding a small quantity of dried, sifted cow manure, and a liberal quantity of silver sand. Ensure good drainage, pot lightly, and place the plants on a shelf in a warm house, shading them from bright sunshine. Maintain a moist atmosphere, but do not permit overhead syringing, as the plants dislike water upon their leaves. So soon as well-rooted, they should be shifted into five-inch pots, and if larger specimens are required, they may be repotted later on, using a compost similar to that for the previous potting, but of a rougher nature and adding a small quantity of Clay's fertiliser. Keep them growing in a warm house, and support neatly with stakes so soon as necessary, keeping the plants free from draughts, as these cause mildew, which soon spoils the attractiveness of the foliage. Give plenty of water when the pots are well filled with roots, when applications of weak liquid manure may also be given with beneficial results.

As the flowers begin to develop the plants may be inured gradually to cooler conditions and, if kept free from draughts and shaded from bright sunshine, will remain in flower for a considerable time; if the main spike is removed after flowering the plants will break and flower again later. The plants should be carefully tended after flowering, for it is then that the corms for the following season have to be matured; in order to effect this, continue watering with weak liquid manure until the foliage begins to die down, after which gradually dry them off.

During the resting period the corms may be stored in their pots in a cool, dry place, but they must not be baked by placing them under a staging close to the hot-water pipes. Should the pots be required for other subjects, the corms may be shaken from the soil—a delicate operation, as they are liable to injury if handled carelessly—and stored in dry sand.

Gesneras may be raised from seeds sown in January and grown in the same way as for seedling Gloxinias or Streptocarpus. They may be increased by division of the corms and also by cuttings, which root readily in heat; if the latter method is adopted, it is preferable to take the cuttings early in the season in order to give the plants sufficient time to form corms, otherwise the plants die outright when they go to rest. Gesneras are sometimes attacked by mealy bug and white fly; the former may be kept in check with methylated spirit applied with a camel-hair brush to the affected parts, and the latter by fumigation with "G" grade cyanogas. Incidentally, this fumigant deserves to be better known, for it is a safe and sure means of combating white fly, and is non-injurious to plant life if the directions are carried out correctly, while the cost per 1,000 cubic feet of house is about one-fifth that of the cost of the liquid compounds usually employed. *A. J. Turner.*

THUNBERGIA ERECTA.

A charming decorative plant for embellishing the stages in an intermediate house is Thunbergia erecta, a native of tropical West Africa. It is of rather dense, shrubby growth, and eventually attains a height of three or four feet, but smaller specimens in five- or six-inch pots bloom freely and are well adapted for the purpose mentioned.

The opposite leaves are rich dark green above and paler beneath. They are shortly petiolate, and pointedly ovate in shape, with slightly sinuately-toothed margins. Throughout the summer and autumn the Gloxinia-like flowers are produced freely. The funnel-shaped corolla possesses a curved tube, which is white without and bright yellow within, and so contrasts effectively with the rich purple of the five sub-rotund, obcordate lobes of the limb. The corolla tube is between two and three inches in length, and the diameter across the limb from one-and-a-half inch to two inches.

Cuttings root readily in the spring, and, if potted on in an open, peaty compost, soon make plants of good size, and bloom freely in their second year. T. erecta is not at all exacting in its requirements, but revels in a moist atmosphere, and requires syringing freely during hot weather. During the winter time it is well to reduce the water supply somewhat, and place the plants in a temperature of 55°F., as at this time they rest partially. Lightly prune any straggly growths in the early spring, repot, and introduce the plants to a warmer temperature just as active growth commences. *T. H. Everett, New York.*

HIBBERTIA VOLUBILIS.

This handsome member of the Natural Order Dilleniaceae, is a native plant of New South Wales. It is the largest-flowered member of the genus, which comprises some seventy species. The terminally-borne blooms are a very pure yellow in colour and from two to two-and-a-half inches in diameter. They are slightly foetid and appear during April. As its specific name implies, H. volubilis is a climbing plant.

This subject grows well in a compost of peat and loam, or in peat or loam separately. It is well, however, to remember that any suggestion of bad drainage is fatal to its well-being, therefore a generous amount of sand should be added to the compost to ensure porosity. Propagation may be effected by means of cuttings.

H. volubilis is by no means a hardy plant, but if planted out in a corridor or allowed to clothe a pillar in a cool greenhouse it will thrive and prove very attractive with its glossy, dark green foliage and bright yellow flowers. *F. H. Wright, University Botanic Garden, Cambridge.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XX.—SOME TREE RHODODENDRONS.

TREE Rhododendrons are characteristic of the middle temperate forest, where the mountains are high enough, in regions of persistent rather than heavy summer rainfall, and considerable winter snowfall. First met with as scattered trees, of no great height, and with leaves of average size, in the lower temperate rain forest (where R. arboreum, R. Mackenzianum and others of the 'Stamineum' series, such as K.W. 8,056, and many of the 'Irroratum' series, such as the royal purple-flowered K.W. 8,044, are found), they become dominant once the Conifer forest is reached. Between 9,000 and 11,000 feet, big-leafed, tree Rhododendrons may form quite fifty per cent. of the forest, although from a distance one might never suspect it, as they are far overtopped and smothered by the Coniferous trees which form the bulk of the remainder; these Conifers are usually Tsuga species or, perhaps, Pinus excelsa, Juniperus species and finally Abies, with Larix Griffithii scattered through. Beneath this Coniferous canopy there are also a certain number of deciduous trees mixed with the Rhododendrons, such as species of Acer and Betula, Magnolia rostrata and M. mollicomata (also M. globosa, when it it a tree and not a shrub), and a few Araliaceae, including Gamblea ciliata. At still greater heights, even before the forest has given place to scrub, where only Abies and Larix can withstand the drought, the Rhododendrons dwindle in size again—although they increase in numbers—and assume a bush-like habit.

On those mountain ranges where the climate, or, at any rate, the air, is drier, with a long winter and a short summer, are found tree species of the 'Lacteum' series, such as R. Beesianum; and although these may grow socially and have good-sized leaves, they fall rather outside the scope of this chapter, being found at altitudes over 11,000 feet. Typical Rhododendron forest, as developed in the mountains of Indo-Himalaya, from Sikkim in the west to the Salween river in the east, is composed chiefly of species belonging to the 'Grande' and 'Falconeri' series, with scattered trees of the 'Thomsoni' and other series. The species have these points in common:—Trees from forty feet to sixty feet high, with massive but short trunks, more or less erect, but not infrequently growing out from the steep flank of the mountain at an angle approaching the horizontal before curving into the vertical; the horizontal portion then being, as a rule, flattened from side to side; the trunk soon diffusing into a number of gnarled and angular limbs, which fork abruptly again and again into a spreading crown of zig-zag branches; leaves big and thick, sometimes very big, woolly, or with a skein of closely-woven hair below, like a glistening skin (glabrous and smaller in the 'Thomsoni' species); and fat, globular trusses of closely-packed flowers, purple, yellow, or white, usually blotched at the base but not speckled, which open in early spring—April to May. In a good year, the temperate rain forest, when viewed from above, is a never-to-be-forgotten sight, thousands of light-coloured buoys tossing and riding on a dark green sea, which the breezes ruffle into ever-changing hues of silver and russet. This, indeed, is something which the introduction of any number of plants into Britain or anywhere else, can never hope to reproduce; on the other hand, we can grow individual specimens as the plant collector always hopes to discover them, but, in fact, never does.

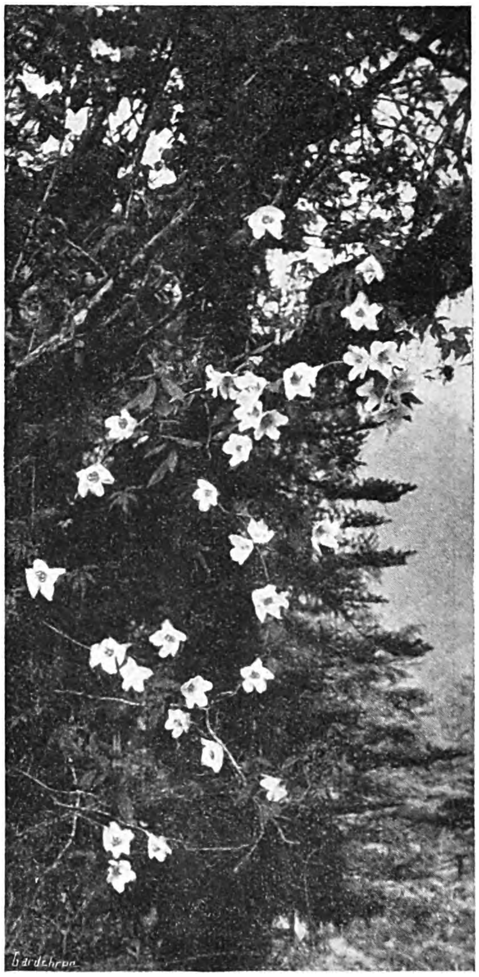

FIG. 181.—AN EPIPHYTIC RHODODENDRON OF THE 'EDGEWORTHII' SERIES.

So much in general. The forests of the Delei valley were uncommonly rich in tree Rhododendrons, both big- and medium-leafed, so I will now pass on to the particular.

The first 'Grande' was met with early in April; probably I did not go high enough to get within effective range, for although I saw a few scattered trees, they had neither flowered the previous year nor intended to flower this. Not until we reached Camp III, where the mountains rise to loftier heights, did we meet with real Rhododendron forest. On April 24, at 8,000 to 9,000 feet, we found R. sino-grande (Fig. 183) coming into bloom. Even when out of flower it is easily distinguished from allied species by the size of its leaves, which have a bright yellow midrib; in flower, the size of the trusses distinguishes it. The flowers are a rather weak yellow, with a small and uncertain purple flash at the base, and for colour are not nearly so striking as those of some other species; nevertheless, it is a noble tree, and an inspiring sight in full bloom. It is worth noting that young plants which have not yet reached the flowering stage have larger leaves than mature trees. R. sino-grande has a fairly wide range, and in my experience, shows little variation from the Tsango gorge at the eastern end of the Himalayas in the west, to the Salween valley in the east. Between these extremes I have collected it at several places, notably in the Seinghku valley (at the headwaters of the Irrawaddy) in 1926, and in the Delei valley; curiously enough, I had never seen it in good bloom until 1928.

It was in early May that we first saw forests of mixed tree Rhododendrons (Fig. 182), by which time we had reached Camp IV, 5,000 feet, and were enclosed by mountains white with snow. On May 5, I ascended a ridge to 9,000 feet, and at last found myself in the Rhododendron forest; three 'Grande' species were in flower. R. sino-grande, the first species met with, was passing over, but at its top limit was still in fair bloom. Another species had a cream-coloured, eight-lobed corolla, much like that of R. sino-grande, but smaller, and with only eighteen instead of twenty-four stamens; the most pronounced difference, however, was the much smaller leaf with rufous fur below—a loose covering, not woven into a tight skin. Indeed, this species recalled R. Falconeri rather than R. grande, and probably belongs to that section (K.W. 8,163). Just bursting into boisterous yellow blossom was a third species. It had leaves silver-plated beneath like those of R. sino-grande, but much smaller, long and narrow; the flowers, however, were a smart, bright yellow—the imperial yellow of the late Manchu dynasty—deeper than anything I have seen in 'Grande' Rhododendrons previously.

At the end of May, we went into our first high camp, actually in the Rhododendron forest; by this time the flowers were over. Our immediate roof was formed of the leaves of R. sino-grande, and of the rufous-haired plant; the rain made a fine noise on this all-weather hood, and for half-an-hour after it started not a drop fell in our open-air summer-house, an advantage cancelled by the fact that for half-an-hour after it had ceased to rain outside, water dripped heavily into our parlour!

Four more species were prominent in the forest here. One, with rather small leaves, buff below and with outstanding primary veins (K.W. 8,194) calls for little notice, as I did not see it in flower. It was almost the first 'Grande' met with on this particular ridge (sharing the ground with R. sino-grande) and, indeed, never seems to go very high; certainly not beyond the Tsuga belt. The next, K.W. 8,251, is more of a puzzle. I just missed it in flower, but from fallen corollas ascertained that the colour is pinkish-purple. Such a colour is, I believe, unknown in the 'Grande' series, and, indeed, the five-lobed corolla and ten stamens did not point to that relationship. On the other hand, the large trusses, and the big leaves with loose, woolly, white fur beneath, turning grey with age (and thereby recalling those of R. Macabeanum) emphatically point to 'Grande.' Anyhow, a fine tree, and a pretty puzzle; I must have missed something unusual, not seeing it in flower. Between 10,000 feet, where it first appeared, practically at the base line of Abies, and 11,000 feet, where it began to get scarce, it often formed an effective portion of the Rhododendron forest, growing both socially and scattered.

The last three species with which it is convenient to deal here, take us to groups other

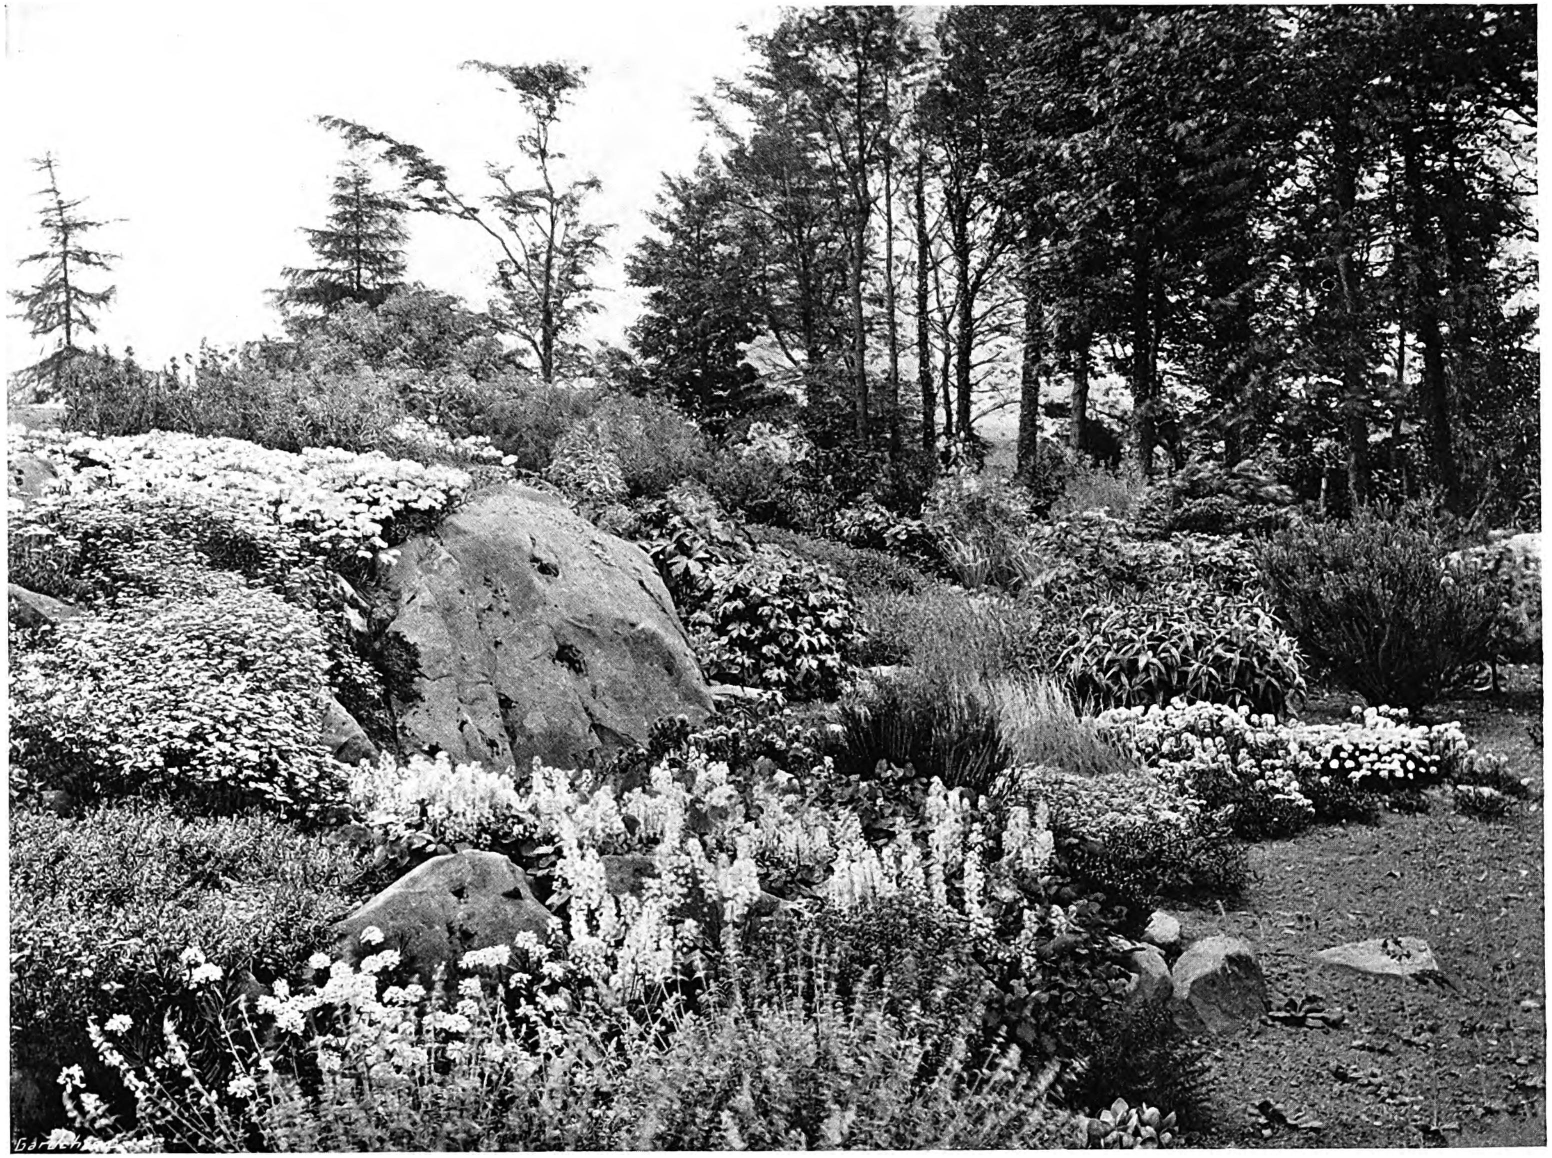
Supplement to THE GARDENERS' CHRONICLE.



THE ROCK GARDENS AT ROWALLANE.

than 'Grande' and 'Falconeri.' The first, a big tree brand of 'Thomsoni,' bore fat fists of purple flowers, and comparatively small leaves. It was chiefly remarkable, however, for its glassy-smooth trunk, on which even the ever-ready moss failed to lodge—except when the trunk stuck out horizontally like a pipe from the mountain face. This was surprising in a forest almost every tree of which was muffled and swaddled in moss to such an extent that often its identity was difficult to determine beneath the disguise! Even the 'Grande' trees were moss-bound to some extent, although they supported few epiphytic shrubs, a circumstance not difficult to account for; epiphytes live on skyscrapers in order to reach the light, which the overlapping leaf rosettes of the Rhododendrons effectively block out. The absence of moss from the 'Thomsoni' trees is probably a mere mechanical result, due to a smooth, slippery surface and few niches; the 'Grande' trees, with their rougher bark, support a certain amount, but the absence of suitable landing grounds on the even trunk accounts for its moderation.

Next, K.W. 8,300 is a smallish tree, scattered among 'Grandes,' but not of them. The leaves, which resemble those of R. ponticum at first sight, have a thin, rust-brown skin beneath, suggestive of the 'Lacteum' series, and the glabrous fruits support that view; but the flowers were long over even at the end of May, and the tree 'Lacteums' do not usually flower so early as all that. Lastly, the common but beautiful pink-white 'Barbatum' K.W. 8,164, dominated the narrow parts of the ridge and occurred scattered throughout the lower parts of the Abies forest; it also is a small tree. *F. Kingdon Ward.*

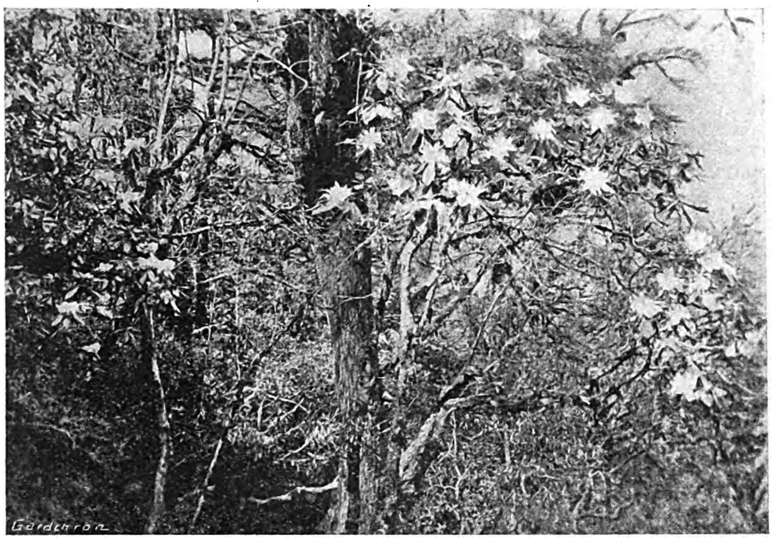


FIG. 182.—THE TANGLE OF THE RHODODENDRON FOREST.

THE TULIP.*

The Tulip is not an English or even a European flower. In Europe there is possibly one wild species, T. australis, the nodding-headed, yellow "Tulip of Bologna" of the early herbalists, which is possibly wild in the Apennines, in Sicily, in the Cevennes, and some localities in Spain and Portugal. But the species which is sometimes credited with being wild in England, T. silvestris is, undoubtedly, a garden stray, which both here and on the Continent is only found on land that has at some time been cultivated. The garden Tulip first became known to western Europe through Busbequius, an ambassador of the Emperor to the Sultan, who met with them on his way to Constantinople in 1554. Busbequius sent home bulbs and seeds, but there were other sources of importation, and the first record we have is that Gesner saw one flowering in 1559 in the garden of Councillor Herwart, in Augsburg. As a flower, it leapt into instant fame, and as it was a time of great activity in gardening, by the close of the century the Tulip was widely distributed in Vienna and Germany, in Holland and Flanders, and in England, France and northern Italy.

But when the Tulip arrived from the East it was already a made flower, that is, it possessed a number of varieties which, however, in the general run of their characteristics, do not differ at all from the garden Tulips of to-day. The original Tulip had narrow petals which came to a point; many of the existing garden Tulips still have that character, but the western gardeners have selected, by preference, Tulips with short, rounded, broad petals, forming a cup. It is still unknown how this eastern garden Tulip arose. None of the species that have since been discovered in western or central Asia, the real home of the genus, can be appealed to with confidence as the source of the garden Tulip. All the varieties of the garden Tulip are fully fertile with one another, which is some argument against a hybrid origin. Again, among the garden Tulips are both white and yellow grounds, yet no species akin to the garden Tulip possesses a white ground. One might still suppose that the white ground had arisen in cultivation as a "mutation," were it not for the fact that the white ground behaves as a simple "dominant" to the "recessive" yellow ground, and dominant mutations are very rare. For the present we can do little more than speculate about the origin of the garden Tulip; we shall probably get some light from breeding experiments with Tulip species, but these are slow because it takes six years before a Tulip reaches the flowering stage from seed-sowing. The origin is certainly remote in time, the locality probably Persia.

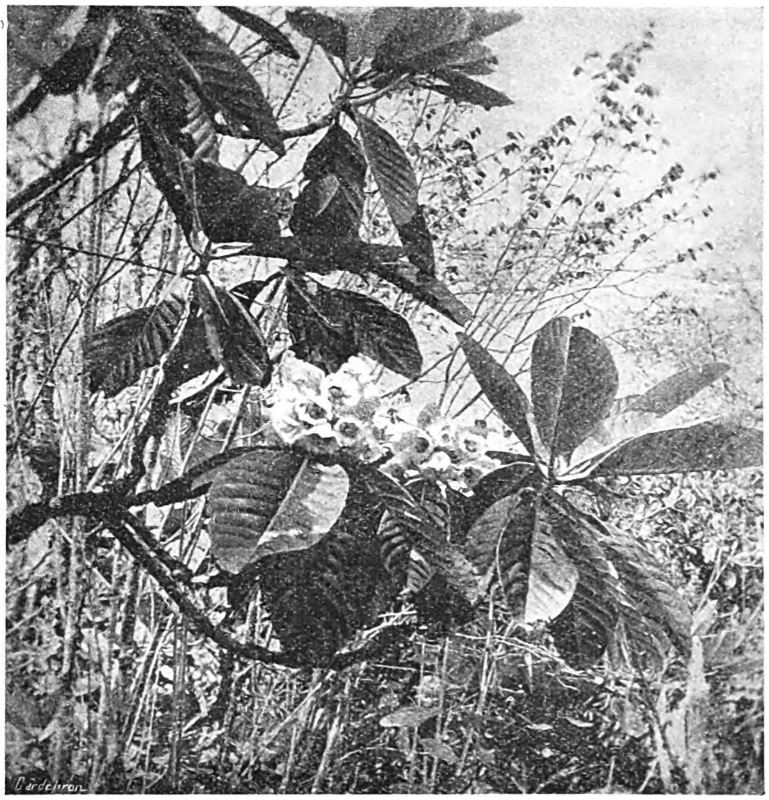

FIG. 183.—RHODODENDRON SINO-GRANDE IN FLOWER AT 8,000 FEET ALT.

From its earliest arrival in Europe the garden Tulip showed one peculiarity exhibited by no other flower. The seedlings are self-coloured when they first bloom,—pink, crimson or purple, or brown, orange or scarlet. Suddenly, in any year, some of them may become variegated and show crimson or purple streaks upon a white ground or brown streaks upon a yellow ground. This change is called "breaking," and is permanent in the sense that the offsets from the bulb that "broke" are also broken. Yet it is not reproduced in seedlings from the broken bulbs and is therefore not a case of "sporting" in the usual horticultural sense of the word. The broken flowers have always been most prized by the fanciers; formerly, the early, unvariegated forms were only kept as stepping stones to the broken varieties, and were known as "breeders." Nowadays it is the breeders that are chiefly grown for decorative purposes.

"Breaking" remained unexplained until recently, when certain analogies led to the suggestion that it might be due to a "virus," one of the ultra-microscopic, filter-passing agents such as cause mosaics and variegation in Abutilon, Potato and Tomato. Last year, Miss D. M. Cayley, at the John Innes Horticultural Institution, succeeded in grafting unbroken Tulips on broken ones, whereby they were induced to break to the extent of over thirty per cent. Similarly, introducing plugs of "broken" tissue into unbroken bulbs induced breaking, so that the evidence is strongly in favour of "breaking" being induced by the transmission of a virus. The question is, then, of the agent effecting the transmission in nature. With many plants some species of aphis carries the virus, and at least four species of aphis are found on the Tulip at some stage or other. A year or two back, Dr. E. J. Collins, of the John Innes Institution, got evidence in favour of transmission by aphis, but not conclusive because the controls were not free from infection. More extensive trials are being conducted by Mr. McKenny Hughes with each of the four species of aphis, in one case with a positive result so far as one season's test can be trusted. It is, perhaps, significant that the aphis inculpated, Myzus persicae, is the chief transmitter of Potato mosaic. While the story is still incomplete, the hypothesis that "breaking" is due to a transmissible virus is at least reasonably probable.

---

* Abstract of a Lecture delivered by Sir Daniel Hall, Director of John Innes Horticultural Institute, at the Royal Institution of Great Britain, on May 3. The lecture was illustrated by living specimens and lantern slides.

There are several other strange "sports" among Tulips. For example, Parrot Tulips with the petals cut and laciniated and splashed with body colour and even with green, have been known since 1665. Most of the Parrot Tulips are red varieties of unknown origin, but of recent years one or two have arisen among known varieties with white grounds as "sports," but whether they breed as such has never been ascertained. It seems a good working hypothesis to suppose that "parroting" is also due to a virus or a combination of viruses, and Miss Cayley has started experiments to test this idea. Sports of a normal type are not unknown among Tulips, generally a colour change, as, for example, to a deeper shade of pink. Sometimes the ground colour changes and a Tulip that is flushed with pink on a white ground throws a sport flushed with orange on a yellow ground. It is noteworthy that the only changes of this kind recorded are from the white to a yellow ground, from the dominant to the recessive, as though the change came about by loss.

One kind of sport, however, remains inexplicable—the occurrence of "thieves." A "thief" is a sport which has been known to occur in many varied stocks of Tulips, and the odd thing is that the thief is much the same sort of Tulip whatever the variety from which it has originated. It is a narrow-petalled, weak-looking flower flushed with pink on a ground often tinged with yellow, so characteristic that in the past it was even endowed with specific rank as T. platystigma. Although thieves have been known for a long time, it has only recently been made certain that they represent definite changes in a variety and are not rogues due to accidental mixture of another stock. Until they have been investigated by breeding experiments it is almost useless to speculate on their nature.

NOTICES OF BOOKS.

Fertilisers and Manures.

The third edition of Sir Daniel Hall's far-famed book on *Fertilisers and Manures*[*] is now available, and will be welcomed by everyone. Since the appearance of the second edition, issued in 1921, mainly for the purpose of discussing some of the fresh fertilising materials developed during the war, many changes have taken place in our knowledge of soil problems and their relation to manuring. It has, therefore, been considered advisable to subject the second edition to an extensive revision.

Chapter III deals with fertilisers containing nitrogen and consists of an informative account of the immense progress that is being made with the artificial production of nitrogenous compounds from the air. Of these, nitrochalk, prepared by Imperial Chemical Industries at Billingham, will be of special interest to growers in this country. Ammonium nitrate made artificially from its elements, being too concentrated for even distribution as a fertiliser, is mixed with carbonate of lime; hence its name. It contains fifteen-and-a-half per cent. of nitrogen in an active form, and, as it also contains forty-eight per cent. of carbonate of lime, which would improve the reaction and texture of the soil, it should rapidly become a fertiliser of the highest class. During 1928, upwards of 250,000 tons of nitrogen products were made at Billingham and marketed, mainly as sulphate of ammonia. From 1910 to 1926, the total world production of artificial inorganic nitrogen compounds increased from 665,000 tons to 1,385,000 tons. An up-to-date account of the production of artificial farmyard manure is contained in Chapter VIII. According to the Adco patent, straw, and, in fact, any kind of waste plant material which was formerly simply burned, with the loss of its valuable nitrogen, can be converted into a dark brown mass hardly distinguishable from ordinary farmyard manure. On many soils green manuring has been shown to be extremely valuable, especially when there is any shortage of farmyard manure. The real difficulty experienced in utilising green manures on many soils is the way it depletes the water supply for the succeeding crops. Perhaps, after all, the Adco principle will be a more effective means of making good the universal shortage of farmyard manure rather than green manuring.

The chapter dealing with potash fertilisers gives a comprehensive account of the position of the Continental potash industry. The Alsatian deposits are now situated in what has become French territory since the war. It is understood, however, as Sir Daniel explains, that a working arrangement exists between the French and German producers, both as to prices and markets. As a consequence, prices, although below their former level, have not been reduced by unrestricted competition between two such great sources of supply. We are also reminded that the Stassfurt and Alsatian potash mines will probably no longer be the only ones in the field, inasmuch as plans have been suggested for developing commercially the deposits of a dried-up lake-bed in Abyssinia, and also for extracting the potash on a large scale from the waters of the Dead Sea. These waters contain no less than 0·95 per cent. potash in a total salt content of thirty-three per cent.

According to the new Fertiliser and Feeding Stuffs Act (1926), dealt with at some length on p. 375, local authorities are now obliged to appoint an official analyst and an official sampler. The latter has the power to enter the premises of makers and sellers of fertilisers and there take samples, so that the trade is, to a certain extent, now under official control, not, as formerly, set in motion by the purchaser, who in many cases was reluctant to let the vendor know he was having the stuff analysed. Sir Daniel recommends all growers to check regularly their purchases of fertilisers by an official analysis.

The remaining chapters—there are fourteen in all—deal with mixed fertilisers, materials of indirect manurial value, theories of fertilising action, systems of manuring crops, and the valuation and purchasing of fertilisers.

Those who have not been trained on Sir Daniel's *Fertilisers and Manures* might be reminded that the book is primarily intended to serve as a guide to a greater skill and knowledge in the use of fertilisers and manures. There is no lack of text books which give an account of the manufacture and composition of fertilisers, and their analysis; but as this book is intended for growers who are using fertilisers, and students at horticultural and agricultural colleges who are going to use them, Sir Daniel has not troubled to write much about these factors, but has concentrated on the practical side of the business rather than the purely technical. His book is, in fact, a perfect blend of science and practice, and it is hard to suggest how it could have been better written. Attention might also be called to its extremely reasonable price—another point in its favour.

The reviewer has only noticed two, unimportant, misprints. Chapter VIII is wrongly paged in the contents; p. 186 instead of p. 193, and on p. 172, line 10, "contained" should read "obtained"; a slip taken over from former editions. *F. V. D.*

A Seventeenth Century Garden.

The Herbals of the sixteenth, seventeenth and eighteenth centuries contain a great deal of curious information, part real, part imaginary, about the "vertues" of plants. In them we read many strange things, how plants are governed by the stars, and how each has a use to perform in the service of mankind. Miss Meighn has recently compiled a delightful little book[*] of "incomparable recipes and choicest curiosities of many good huswives and learned doctours of physicke" culled from these and other works of the period, which makes very pleasant reading.

Gardens are not forgotten. There is a curious plan of a seventeenth century garden, and in the section headed "Divers Delightes concerning Gardens and Orchards, with the Vertues and Uses of Flowers and Fruits," we read as follows: "When God had made a man after his own Images, in perfect state and would have him to represent himself in authority, tranquillity and pleasure upon the earth, he placed him in Paradise. What was Paradise but a garden, an Orchard of Trees and Herbs, full of pleasure and nothing there but delights . . ."

The seventeenth century author proceeds to extol the delightsomeness of gardens, lingering over the names of his favourite flowers—Roses of several sorts, Woodbine, Cowslips, Primroses and Violets. He then adds:—"And all these by the skill of your Gardiner, so comelily and orderly placed in your borders and squares, and so intermingled that one looking thereon, cannot but wonder to see what Nature corrected by Art, can do."

There is a romantic charm about these old authors, even the quaintness of their spelling having an attractive air of freedom. No doubt they were shockingly unscientific; but there is a time for science and a time for romance and imagination, and it is good sometimes to give free rein to fancy in the contemplation of our gardens and the myriad beauties of Nature.

We are, therefore, much indebted to Miss Meighn for her charming little book, which can be slipped in the pocket and dipped into at any time when fancy would transport us back three hundred years or so. *H. S. R.*

Japanese Crabs and Nectarines.

We learn from an introductory note to this book[†] by the Marquis Nabeshima that, in 1912, a horticultural experiment station was established in a garden belonging to him, which was situated in a suburb of Tokyo, the subjects experimented with being vegetables, fruit trees and flowering plants. Later, as has happened with innumerable nurseries and gardens near London, the experimental ground became surrounded by houses, due to the growth of Tokyo, so that, in 1922, the work had to cease.

The present book deals with the Crabs and Nectarines which were cultivated there and which were of particular interest to Japanese horticulturists as being varieties originating in Japan, or derivatives of native types. Owing to the introduction to Japan of various fruits of superior quality from foreign countries, these native kinds are being rapidly ousted; some of them, indeed, have almost disappeared. One object of this work is, by means of description and illustration, to provide a permanent record of them while it is still possible.

[*] *Fertilisers and Manures*, by Sir A. Daniel Hall. Third edition, revised and enlarged; pp. 414. London: John Murray. Price 8s.

[*] *A Little Book of Conceited Secrets and Delights for Ladies*. . . . . Newly set forth by Moira Meighn. London and Boston: The Medici Society. Price 2/6 net.

[†] *The Crab Apples and Nectarines of Japan*, by Yoshichi Asami. Tokyo, 1929.

The types of Crab (Malus) dealt with are seven, viz., asiatica, prunifolia, micromalus, Halliana, baccata, cerasifera and Sieboldii. Of these, only Halliana, baccata and Sieboldii appear to be represented in a genuinely wild state in Japan. Owing to cultivation and hybridisation, the identity of many forms is difficult to establish, and there is a woeful confusion in their nomenclature. Such familiar specific names as Toringo, Sargentii, Ringo and Zumi all appear here as varietal or synonymic.

The article on the Nectarines of Japan is of purely Japanese interest. The varieties are given under their native names, and in general are admitted to be inferior to introduced varieties although they are often remarkably fertile.

The book is excellently printed in very good English, although mistakes in spelling are frequent. It is illustrated by fifty reproductions of photographs and by an equal number of full-page plates. The latter were drawn by Mr. H. Sanada, who deserves every praise for his work, combining as it does the delicacy, accuracy and charm which has for so long characterised plant portraiture by his countrymen.

BOG AND WATER GARDEN.

GYROSTACHYS STRICTA, RYDB.

This very chaste and deliciously fragrant terrestrial Orchid is a native of the greater part of Canada and the United States, ranging as far south in the latter country as the Rockies of Colorado. It is a bog-loving species and is generally found in sandy, spongy peat, in open, more or less sunny situations, in bogs, and frequently on the shores of pools, both in the lowlands and at considerable elevations above sea-level.

The root system of Gyrostachys stricta (Fig. 184) consists of several more or less spindle-shaped tubers from three-quarters- to one-and-a-half-inch in length, together with a few short, white roots which spring from the base of the stem. The narrowly lance-shaped or narrowly oblanceolate, pointed leaves, from two to eight inches in length, are produced near the base of the rather slender, erect flower stem, which reaches a height of from four to fourteen inches, and is clothed with several rather widely-separated, reduced leaves or bracts.

The flowers are produced in a dense, more or less twisted spike two to four inches in length, mingled with short, narrowly-pointed bracts The individual blossoms are from one-and-a-quarter- to three-eighths-of-an-inch in length, very open at the mouth, with a broad, blunt or pointed upper sepal, narrow petals, and lateral sepals, and an oblong lip, broad at the base, then contracted and dilated and rather wavy at the tip; they vary from pure white to white, shaded green, and are rather thin in texture.

This species blossoms in July and August and should prove attractive on the edge of a pool in an open, sunny spot in the rock garden, or on the margin of an artificial bog, in sandy peat and loam.

G. stricta has, until comparatively recently, been confused with the Alaskan Gyrostachys Romanzoffiana (Spiranthes Romanzoffiana of most British authors), and is no doubt the same plant that is found in western Ireland. The true Gyrostachys Romanzoffiana (Cham.) may be distinguished from the above species by its very short, crowded spike not exceeding one inch in length; by the upper portion of the flower stem being densely glandular; downy—and also by the shape of the sepals, which are sharply toothed at the tip. *A. W. D.*

NYMPHAEAS.

The time has now arrived for giving ponds containing these beautiful plants their annual cleaning. Of all aquatics, none can compare with the Nymphaeas, especially if a choice selection of the newer, beautifully coloured hybrids is grown. The vigorous-growing, larger sorts are unsuitable for small ponds, as they soon become crowded with leaves and cover most of the surface of the water, with the result that both the plants and the water lose their attractiveness.

Such Water Lilies as N. Gladstoniana, N. chromatella, N. Colossea and N. Sumptuosa, should only be used where large stretches of water are available. These, if the ponds are natural and contain a deposit of decaying vegetation, and if allowed plenty of room for development, will not require dividing for four or five years.

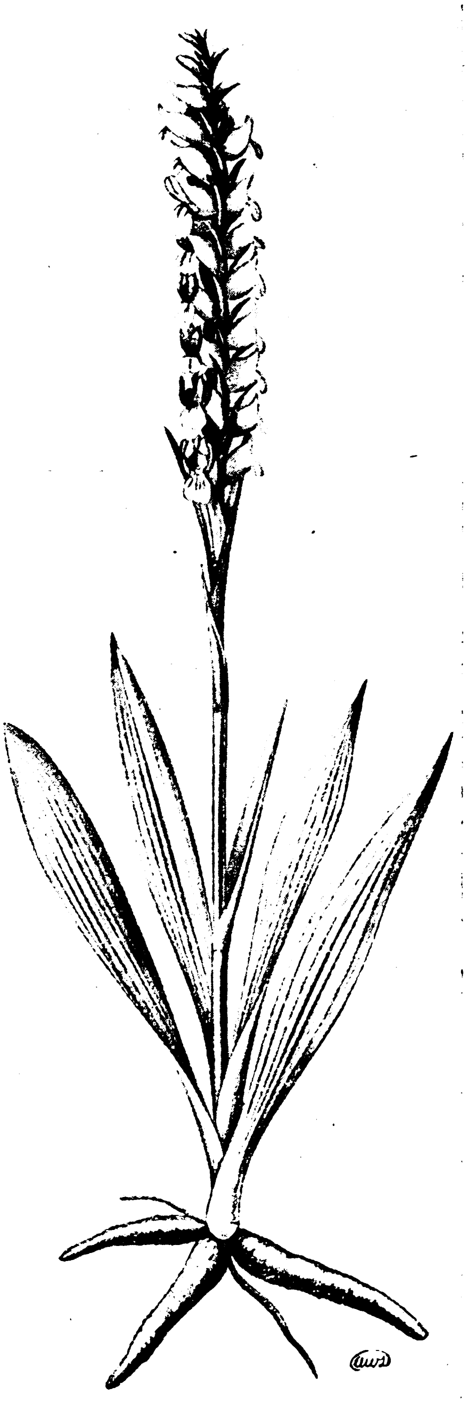

FIG. 184.—GYROSTACHYS STRICTA.

Nymphaeas delight in rich soil, and they should be planted in a mixture of heavy loam, with about one-third of well-decayed cow manure. Various methods are adopted when planting Nymphaeas, the most commonly employed being to fill baskets with prepared compost and plant the roots in these, with only the crown showing above the soil, then sinking the basket in the desired position. Such is the best method for deep ponds, and where it is impossible to drain the water off before planting. In those where the water can be drained off, mounds of the planting material may be placed in the positions selected, and the crowns, when planted, held in position by pegs or stones placed over the roots until they get hold of the soil. Depth of planting is an important factor, and many of the choice varieties will grow in quite shallow water. A depth of from eighteen inches to two feet will be sufficient for any variety, but many of the weaker-growing kinds will be happier in water from one foot to fifteen inches deep. These Nymphaeas are often planted by the margins of ponds, where they are overshadowed by trees; such positions are not suitable, for Nymphaeas require the benefit of full sunshine and still, clear water, before the full beauty of their flowers can be fully appreciated.

The pure, glistening white blooms of N. Gladstoniana, floating on the still surface of the pond, appeal to many, but it is among the delightful hybrids raised by Mons. Latour Marliac and other enthusiastic hybridists, that we find the greatest charm, when we look upon a peaceful sheet of water on which are gracefully floating these glorious flowers ranging from pure white, through every shade of pink, to deep red. Many varieties are offered, all having their good points, and a selection might, with advantage, include Escarboucle, Aurora, Robinsoniana, Arethusa, Formosa, Sioux, Mrs. Richmond, James Bryden, atropurpurea, Brackleyi, Marliacea var. rosea and Murillo.

In the section of small-growing Nymphaeas which can be grown successfully in tubs or small tanks, provided these receptacles are placed in full sunshine, are a few charming varieties. N. tetragona (pygmaea) var. alba, the smallest-flowered member of the genus, needs only two or three inches of water in which to grow successfully. N. t. var. helvola is the sulphur-yellow form, well worth growing. N. odorata var. Exquisite, N. o. var. sulphurea, N. Laydeckeri var. fulgens, and N. L. var. purpurata, are all worth including where small, shallow pools have to be planted.

Of the tropical species, with their gorgeously-coloured flowers, the beautiful N. stellata will succeed in the open and flower during summer if potted and started in a warm greenhouse and placed in its flowering quarters in early June. At Wisley, N. stellata is grown in a tank in the open, which is heated by hot-water pipes passing through it. Under such conditions, this attractive Water Lily grows and flowers freely, its stellate, lavender-blue flowers being greatly admired. When grown like this the tubers should be lifted and replanted every two years, retaining only the strongest crowns for replanting. *F. W. G.*

GENTIANA ANDREWSII.

It may well be argued, and often is, that a member of such a genus as Gentiana—rich in highly decorative garden subjects—which refuses to open its blooms to the light of day, is of no garden value. Yet, for its own special purpose, G. Andrewsii, for such is the member referred to, is not without charm, and is certainly worth growing as a novelty, even although it is not strikingly decorative.

This Gentiana's place is in the bog garden, where it will grow freely, for it is comparatively easy to establish and is a good perennial provided the soil is not too cold and heavy; under the latter root conditions it is not long-lived and gradually dies off.

When happy, the Dumb Foxglove, as it is ironically termed in America, its native country, will produce an abundance of slender stems eighteen inches or more long, which will ramble and trail through the other herbage of the bog garden, to be terminated from July until September with clusters of long, bulging flowers, rich, but rather dull, dark blue in colour and tipped with white. The flowers appear rich in promise, but the plant lover waits in vain for them to open—therefore G. Andrewsii is termed the Dumb Foxglove, and although quaint and a provider of colour in the bog garden at a season when it is needed, it is yet a disappointing plant, and so must remain.

In passing, mention may be made of another Gentian which, although not striking, is yet an acquisition to the bog garden, namely, G. Pneumonanthe, our native Marsh or Heath Gentian, and not uncommon throughout Europe, and Russian Asia—in the British Isles it is confined chiefly to northern England, and is stated to be non-indigenous to either Scotland or Ireland (Bentham and Hooker's *British Flora*). It delights in cool, rather moist and peaty soil, and produces straggly, slender stems, up to about eighteen inches in length, and set with pairs of leaves, the lower oblong-lanceolate, and the upper, in the axils of which the flowers are produced, almost linear. The flowers appear in late summer; they are trumpet-shaped, an inch-and-a-half long, with short, broad, spreading lobes, and are deep blue, attractively marked and shaded with green. There is also a desirable form of G. Pneumonanthe with pure white flowers, speckled with gold and green, while the variety from the Alps, sometimes called G. P. var. arvernensis, is described as attaining double the size of the type, and would appear to be specially worth obtaining. It flowers, like the type, in August, and requires similar cultural treatment. *W.*

TREES AND SHRUBS.

CYTISUS ARDOINII.

If I were ever doomed to grow but one rock-garden Broom, this delightful little species of the Maritime Alps would be my choice. There is a charm about this tiny shrub which is irresistible, and a distinctiveness which never fails. Growing to no more than some four inches high, the decumbent branches spread over a square foot, or perhaps more. The tiny, trifoliate leaves, as well as the twigs and calyces, are densely downy. In April and May the plant becomes a mass of blossom, the blooms being borne in small but numerous clusters at the tips of the previous year's wood. Each of these flowers is nearly half-an-inch in length, and they are a particularly rich nasturtium-yellow. Add to this warm colouring the facts that the blossoms are of unusual substance, and that the standard petal is so rounded and incurved that it gives the flower a full and ample appearance, and C. Ardoinii will never fail to attract admiration in spring.

In any open spot C. Ardoinii will generally do well and prove both hardy and long-lived. Although its disposition to hybridise with other kinds may be a deterring factor with those who desire to increase it by seeds, it has been the means of giving us some valuable hybrids, notably C. Beanii and C. kewensis, of both of which it is the seed parent. The best way to propagate C. Ardoinii is probably by cuttings rooted in very sandy soil in a close frame during late summer. But well-established plants will sometimes give self-rooted branches that can be detached with sufficient roots at the base to start them with the help of a handlight. *J.*

THE LARGEST DAVIDIA.

In *The Gardeners' Chronicle* of March 9, p. 182, there appeared an interesting article on that marvellous tree, Davidia involucrata; may I inform the many readers of this journal that there is in France, I believe, a bigger specimen than any other. It is in the large Arboretum of M. A. Gérard, at La Fosse (Loir et Cher), where some very big and rare trees have been cultivated for generations by the Gérard family. This Davidia stands as a king, set among rare Conifers and evergreens. When we were there two years ago, in the month of May, my friend Professor Bois, of the Museum of Natural History, Paris, and I, could not but admire it. Imagine a dark mass of large green leaves, starred with pure white flowers as big as those of certain Magnolias. The specimen is thirty-eight feet tall, and its girth at three feet is twenty-nine and-a-half inches; it has a horizontal spread of twenty-four feet, and its first branch is about two feet from the ground. Every year—except those of late frosts—it produces from 800 to 1,000 nuts. These germinate very slowly, sometimes only after two or three years, and very irregularly. Indeed, most of them fail to germinate, and it is supposed that fertilisation is rather difficult. This tree was planted in 1906 from Vilmorin's seeds, and the resulting plants are those of the Vilmorin form and not of Wilson's. It began to flower in 1911, and since then it has always flowered more or less every year. *H. Correvon, Geneva.*

PRUNUS PERSICA VAR. FLORE SANGUINEO PLENO.

Passing a garden recently in which an exceptionally fine specimen of this beautiful Peach is established in a setting of dark Pines, its masses of strikingly coloured blossoms completed a picture of exquisite charm and beauty.

It flowers some weeks later than the Almond but is by no means so robust as it, or so vigorous in growth, or tolerant of the impure atmospheric conditions of large towns, where it appears to languish and gradually die out. It is, however, together with the rose-coloured variety, a splendid subject for inclusion in planting schemes where conditions are more favourable. Unfortunately, these ornamental Peaches are very liable to canker, which fact is generally attributable to their being worked on the Myrobalan Plum stock, and they are apt to become slow and stunted in growth. However, much may be done to assist them in this latter respect by judicious mulching and attention during the first few years after planting. *H. G. King, Twickenham.*

SOME PERENNIAL SPECIES OF LATHYRUS.

The Everlasting Peas constitute a somewhat neglected part of a popular family. So far, none of them has been induced to assume colours beyond what occur naturally in a state of nature. Yet they possess so many good qualities that it only needs some variation in colouring to place them in the front rank among herbaceous climbers.

Looking back over fifty years spent in gardens, and noting the development of the annual Lathyrus odoratus, the Sweet Pea, from the three or four varieties exhibited in 1875, it seems not unlikely that hybridisation may yet cause a break in the stereotyped tints of the perennial Lathyrus. Once this has been achieved, breeding and selection will probably bring about a series of varieties having novel and beautiful shades.

The commoner kinds, purchased as small plants or raised from seeds, flourish in any good garden soil, and only need planting firmly in an open, sunny place to secure establishment. Unfortunately, slugs are very fond of the young growths, and will, unless prevented, destroy them in early spring.

To one who has gathered the wild Lathyrus sylvestris trailing over its native hedges under the South Downs, a stiffly-trained Everlasting Pea on a trellis appears as if crucified. True, they need supports to which they can cling with their tendrils at an early stage; it may even be necessary to start by tying the young growths in the right direction, but after that, let the shoots cluster together naturally The result will be less uniform, but far more pleasing to the artist's eye.

Lathyrus sylvestris var. latifolius is decidedly the best garden plant we have in this section. It can be used, with the help of "Pea boughs," to form a handsome mass at the back of a herbaceous border, and may be employed to hide the not always beautiful supports of a verandah or summer-house, but is, perhaps, never seen to better advantage than when planted at the foot of a low terrace wall and allowed to trail over it, making a cloud-like mass of greenery, covered with handsome flowers. The colour of the flowers—a rich purplish-rose—is not always easy to associate with that of other flowers, but that difficulty does not extend to the charming blush variety or the pure white form.

Lathyrus grandiflorus is a native of southern Europe. Its large, purplish-red flowers are beautifully shaped and smooth in contour. As its roots travel beneath the soil and send up a multitude of shoots, it should not be placed near enough to choice plants to endanger them by smothering, but among commoner shrubs it will often hold its own and decorate their branches when their own flowers have faded.

Lathyrus rotundifolius (syn. L. Drummondii), a very attractive Pea, is a native of Persia and Asia Minor; except in the colour and size of its flowers it is a small counterpart of L. s. var. latifolius, which it equals in hardiness and freedom of growth, often reaching a height of six feet when established in good soil. The flowers, borne in racemes, appear in May, and continue until July. All the text-books unite in libelling their colour and describe it as bright rose, pink or rose, making no difference between this Pea and L. s. var. latifolius. As a matter of fact, its colour is most distinct, and is described by an Ipswich firm which catalogues this Pea, as "salmon-red"; writing from memory, this certainly appears a truer description than the other three.

Lathyrus pubescens is a most charming Chilian species, but it can only be grown in the more favoured parts of this country. Seeds are occasionally listed by at least two of our English seedsmen who cater for lovers of rare plants. They should be sown in late summer, wintered in a frame, potted on in February, and planted out at the foot of a south wall in April. If the soil is good, vigorous growth ensues, and support will be needed, a piece of large-meshed wire-netting, as used for sheep enclosures, serving the purpose admirably if fastened securely to the wall. Before winter sets in, a strand or two of wire passed through the mass of growth will secure it against storms, and flatten it somewhat so that it can be protected by a mat. A few shovelfuls of coal ashes will give added protection to the roots. If the winter is a mild one, growth commences early, and on these shoots the dense racemes of large, lavender-coloured flowers appear later. During the recent Andean Expedition, the white variety L. p. var. albus, was found in quantity at Calafquen, Chili (Comber, 1,096). The collector describes it as growing from six to thirty feet in height, in open places at an altitude of 800 feet to 1,500 feet, and succeeding best when its roots are shaded by the bush it climbs on.

Lathyrus nervosus, Lord Anson's Blue Pea, for many years held a great fascination over gardening enthusiasts as something very desirable but unobtainable. Many considered it similar to L. latifolius, with flowers the colour of Salvia patens. Twenty or thirty years ago, seeds of it were often advertised, but when purchased proved to be those of L. sativus, the Chickling Vetch. A full description and history of the true plant appeared in *The Gardeners' Chronicle*, Vol. LXXXI, p. 320, by Mr. J. Coutts, of Kew. The article gives so much information and dispels so many illusions, that it is well worth referring to.

Mr. T. Hay, Superintendent of Hyde Park, was the first to re-introduce L. nervosus, in 1926, and very kindly gave me some seedlings the same year. These plants produced typically purplish-blue and white flowers and later, seeds; a second generation has been raised from them, but the older plants are not "everlasting," for when about to flower the second time, the lower leaves turn yellow and the stem dies upwards gradually, as if the plant had been overwatered. It is also subject to mildew, but this applies equally to L. magellanicus and L. setiger, even when grown in an open field. As L. nervosus is a maritime plant, perhaps some gardener living near the coast has had better success with it.

My plants, grown in well-drained seven-inch pots, in loam, leaf-mould and grit, reached a height of two feet before flowering. The younger generation, from home-saved seeds, has already attained a similar height, and is supported with Birch twigs. A few will be planted outside so soon as the weather is more favourable. *J. Comber, Nymans Gardens.*

THE GENUS PRIMULA.

(*Continued from p.* 326.)

MINUTISSIMA (Jacq.). Minute P.
(Minutissimae.)

A DELICATE, extremely dwarf perennial species, forming large patches of dense, dark green foliage from creeping stolons. The individual rosettes are about three-quarters-of-an-inch across and composed of numerous spathulate-lance-shaped, or broadly lance-shaped, pointed leaves a quarter- to half-an-inch long; margins furnished with sharp or blunt teeth; upper surface usually smooth, underside more or less mealy. Flower stem very short, sunk among the leaves, and bearing at its tip one to three bright purple, stemless blossoms. Corolla three-eighths- to five-eighths-of-an-inch across, divided into five broadly heart-shaped, very deeply cleft lobes; tube a quarter- to three-eighths-of-an inch long, many times longer than the calyx. Flowers in July. (Duby, *Mémoire sur la famille des Primulacées*, t. 1, Fig. 3).

Grows in open, alpine pastures and moorlands, usually on limestone, in the Kumaon and Kashmir Himalayas, and also in western Tibet, at from 12,000 to 16,000 feet above sea-level.

Culture: Grow it in peat and sandy calcareous loam, in an open spot in the rock garden, planted among dwarf grasses or low alpine subjects; or in an alpine house or frame in a compost as prescribed above.

MISTASSINICA (Michx.). Mistassinian P.
(Farinosae.)

This plant is considered by many botanists to be a sub-species of the variable P. farinosa. It has spathulate, or egg-shaped, blunt leaves, wedge-shaped at the base, half-an-inch to three-quarters-of-an-inch long, with sharply-toothed margins; both surfaces are smooth, or at times slightly mealy on the underside. Flower stem one inch to six inches tall, bearing a loose umbel of rose-coloured, pale purple or pale mauve-pink blossoms similar in shape to those of P. farinosa, and about half-an-inch across. Introduced in 1818.

Grows on wet slopes in elevated situations, in eastern North America, from Newfoundland to the Rockies, and is also found in northern Europe.

Culture: As for P. farinosa; an easy plant to cultivate.

MIYABEANA (Ito et Kaw.). Miyabe's P.
(Candelabra.)

A deciduous perennial, but usually biennial under cultivation, with a tuft of oblong-egg-shaped or broadly lance-shaped, blunt or pointed leaves four to eight inches long, gradually tapering to a broad, winged stalk; margins furnished with sharp teeth; both surfaces more or less mealy when young, usually quite free from meal when mature. Flower stem eighteen to twenty-four inches tall, quite free from meal when mature, bearing several superposed umbels of six to ten purple or magenta blossoms, on spreading stalks up to one-and-a-half inch long. Corolla flat, about five-eighths-of-an-inch across, divided into five broadly heart-shaped lobes; tube cylindrical, about five-eighths-of-an-inch long, with a ring in the mouth. Flowers in May. *Bot. Mag.*, t. 8,603. Introduced in 1913.

Grows in moist alpine pastures, etc., on Mount Morrison, in Formosa, at about 17,000 feet above sea-level.

Culture: As for P. japonica; quite hardy in southern and western Britain.

MODESTA (Bisset et Moore). Modest P.
(Farinosae.)

Pax made this plant a sub-species of P. farinosa, but by others it is considered a good species. It produces a tuft of spathulate, mealy leaves, one inch to two inches long, with the margins furnished with saw-like teeth. Flower stem slender, two to four inches tall, bearing an umbel of about ten lilac-purple blossoms. Corolla about five-eighths-of-an-inch across, divided into five somewhat narrow, deeply cleft lobes; tube twice as long as the calyx.

Grows in damp, open pastures in elevated situations in Japan.

Culture: As for P. farinosa (Illustrated in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913). Introduced in 1911.

Var. Fauriei (Franch.). This form is considered to be a good species by Pax. It is distinguished by the sulphur-yellow meal on the undersides of the leaves. The flower stem reaches a height of two to four inches and bears a few-flowered umbel of rose-coloured flowers half- to five-eighths-of-an-inch across. Japan (Illustrated in *Notes from the Botanic Gardens, Edinburgh*, 1913.)

Culture: Grow it in the same soil and position as for P. farinosa, but under drier conditions.

MOLLIS (Nutt.). Downy P.
(Cortusoides.)

This somewhat robust Himalayan perennial species produces a tuft of densely downy leaves with rounded blades about three inches long, deeply heart-shaped at the base, rather thick in texture and blunt at the tip; they are borne on stout, downy stalks three to six inches long; margins lobed and furnished with irregular teeth. Flower stems numerous, rather stout, downy, twelve to twenty inches tall, bearing two to five superposed umbels of few, or many, rosy-lilac to deep rose-coloured blossoms. Corolla about half-an-inch to three-quarters-of-an-inch across; lobes egg-shaped, notched, flat; tube cylindrical, about five-eighths-of-an-inch long, exceeding the calyx in length. Flowers in August. Introduced in the year 1845. (*Bot. Mag.*, t. 4798).

Grows in damp, shady places in the Bhutan Himalayas, at rather low elevations.

Culture: This species is rather tender, and is only suitable for outdoor culture in warm localities; it may be tried in a very sheltered, shady spot, in peat and loam well-drained in winter.

MONANTHA (W. W. Sm.). Solitary-flowered P.
(Farinosae.)

This dwarf plant is a sub-species of P. gemmifera (Batal.); it forms a sparse, loose rosette of sub-orbicular or broadly spathulate, somewhat fleshy leaves half-an-inch to one inch long, rounded at the tip, somewhat abruptly contracted at the base into a winged stalk equalling the blade in length; margins toothed and edged with minute, capitate glands; both surfaces sparsely coated with white meal. Flower stem flexuous, one-and-a-half- to two-and-a-half inches tall, sparsely coated with white meal and bearing at its apex a solitary, purplish-rose blossom on a slender stalk about a quarter-of-an-inch long. Corolla flat, smooth, half- to three-quarters-of-an-inch across, with egg-shaped, notched lobes; tube cylindrical below, slightly dilated upwards, about half-an-inch long. Flowers in July.

Grows in stony, alpine meadows on the the Mekong-Yangtze Divide, in Yunnan, western China, at about 14,500 feet above sea-level.

Culture: As for P. farinosa.

MOORCROFTIANA (Wall.). Moorcroft's P.
(Nivales.)

This handsome, deciduous perennial is considered to be a sub-species of P. macrophylla (Don). The somewhat thick leaves, produced in tufts, and not fully developed at flowering time, have lance-shaped or narrowly oval blades, tapering to a winged stalk dilated at the base, in all from two to four inches long and about five-eighths-of-an-inch wide; margins usually quite entire; both surfaces more or less smooth, underside at times slightly mealy. Flower stem four to eight inches tall, stout, bearing an umbel of purple blossoms on short, stout stalks. Corolla about three-quarters-of-an-inch across, with heart-shaped, notched lobes.

Grows in damp alpine meadows in Kumaon, Kashmir and south-western Tibet.

Culture: As for P. macrophylla.

MOOREANA (Balf. f.). Moore's P.
(Capitatae.)

This beautiful, deciduous perennial plant, which is in cultivation under the name of P. capitata, of which it is probably a sub-species or microform, is the finest member of the section Capitatae. It produces a rosette of membranous foliage which is contemporary with the blossoms; the oblong-egg-shaped or broadly lance-shaped blades are from four to six inches long, rounded at the tip, gradually tapering to an obscure, winged stalk; margins furnished with obscure, irregularly-toothed lobes with horny tips; upper surface green, furnished with meal-producing, glandular hairs; underside densely coated with white meal and coarsely reticulated, Flower stem nine to twelve inches tall, stout, densely covered with white meal, erect, bearing a many-flowered head of reddish-violet blossoms. Corolla concave, about three-quarters-of-an-inch long, divided into five overlapping, egg-shaped, nearly square or rounded, notched lobes; tube cylindrical below, inflated above, red at the base, white above, with a green throat and an obscure ring. Flowers in August and September.

Grows in damp, rocky alpine pastures, in the Sikkim Himalayas, at 10,000 to 16,000 feet above sea-level.

Culture: As for P. capitata.

MORSHEADIANA (Ward). Morshead's P.
(Candelabra.)

A handsome, dwarf, perennial species with a rather stout rootstock emitting numerous thick roots. The leaves, in rosettes or tufts, are membranous, with broadly lance-shaped blades two to three inches long, rounded at the tip and gradually tapering to a winged stalk; margins furnished with sharply pointed, hooked teeth; both surfaces smooth, underside paler than the upper. Flower stem about three inches tall, smooth, bearing from three to eight golden-yellow blossoms in an umbel, on stalks a quarter- to half-an-inch long. Corolla about half-an-inch across, with rounded, egg-shaped, entire or obscurely-toothed lobes; tube cylindrical, about half-an-inch long. Flowers in June and July.

Grows on steep alpine slopes in very dwarf herbage on Doshong La, in south-eastern Tibet, at 10,000 to 13,000 feet above sea-level.

Culture: Good fibrous loam and grit, in an open, sunny spot well supplied with water when the plant is in growth, should suit it.

MOSCOPHORA (Balf. f.). Lichen P.
(Bella.)

A very beautiful, dwarf, perennial sub-species of P. bella (Fr.); it produces stolons or offsets about three inches long from the main root-stock, each with a tuft of oblong-elliptic, egg-shaped or narrowly spathulate leaves, about five-eighths-of-an-inch long, with blunt tips and long, winged stalks; margins irregularly toothed; upper surface dull green and sparsely furnished with meal-producing, glandular hairs; underside densely coated with white meal. Flower stem slender, about five-eighths-of-an-inch tall, coated with white meal and bearing a solitary lilac blossom. Corolla about one inch across, concave, downy, with wedge-shaped or nearly square segments divided into two oblong, deeply cleft lobes; tube about half-an-inch long, smooth outside, furnished with a sparse tuft of white hairs in the throat. Flowers in August.

Grows in moist, stony pastures among moss and Liverwort, on the mountains of the Shiveli-Salween Divide in Yunnan, western China, at about 11,000 feet above sea-level.

Culture: Peat, and gritty, calcareous loam, in an open spot well supplied with moisture when the plant is in growth, are indicated. *A. W. Darnell.*

(*To be continued.*)

MARKET FRUIT GARDEN.

With only 0·77 inch of rain, April did very little towards breaking the extraordinary spring drought. It was, in fact, the driest April of which I have any record. In view of the frosts which were frequent towards the end of the month, it was probably fortunate that the weather was so dry. To this, and to the fact that earlier conditions had been of a hardening rather than a forcing nature, may be attributed the slight apparent damage done by frosts of 6° in the air which occurred on several occasions. Ground frosts were much more severe. What may have been the actual effect of the cold weather on the setting of fruits remains to be seen, but the visible damage was surprisingly light. I expected to find the pistils of fully-open Plum blossoms blackened by the frost, as happened with some varieties in the last two seasons, but this did not occur. The blossom of Black Currants was affected in low-lying spots, particularly in the case of Baldwin, which is the earliest to flower. It was the end buds on the bunches that were damaged; and the result will be short bunches and a reduction in the weight of the crop. I do not altogether like the appearance of some of the Apple blossom, now in the pink bud stage. The first leaves surrounding the buds have a pinched look, probably due to the severe frosts experienced earlier in the spring. A few buds of Bramley's Seedling were frozen through in the early green stage, and now drop off at a touch and are found to be brown inside. This damage is not sufficient in my plantations to affect crop prospects materially; and I should not have noticed it if I had not looked specially for it, after hearing reports of wholesale injury of this kind in some parts of Kent. It is curious that Bramley's Seedling, usually considered to be one of the hardiest varieties, should be the only one to be subject to this early frost damage.

The first blooms of Plums opened on April 19, and all varieties, except Pond's Seedling and Belle de Louvain, were in full bloom by the end of the month, as were most varieties of Cherries. This is about a month later than last year, which was a medium or normal spring. No Apple blossom was open in April. It was generally hoped that such a late blossoming period would prove to be safe, but such hopes were disappointed. However, my place is fairly high up and within sight of the sea, which means that I usually suffer less frost damage than many growers less fortunately situated; so I am not unduly alarmed.

Plum Blossom.

If the Plum blossom manages to set in spite of the cold weather there should be a good crop. Young trees of all varieties are flowering profusely, and there is a better display in the older plantations than I anticipated. In the latter, Monarch and Pond's Seedling, which cropped well last season, are the only partial failures. Rivers' Early Prolific, Czar and Victoria bloomed profusely, and President moderately. Some large trees of Belle de Louvain will be a mass of blossom in a few days.

In such a spring much good work in fertilising fruit blossom is done by wild humble bees. Many of these insects were busy among Plums and Black Currants on cold and windy days when very few hive bees were to be seen. They always seem to do a great deal of the fertilising of the latter crop. I fancy these bees are particularly numerous in my district, which may account for the fact that Black Currant Boskoop Giant does not "run off" so seriously as it does in some places.

Spraying Against Scab.

The pre-blossom spraying of Apples for the prevention of scab began in the last week of April. Last year, I only just got round before the blooms opened; so this season spraying started at a rather earlier stage in the development of the blooms. After all, no one knows quite which is the best stage for this operation; and, on a place of any size, one certainly cannot catch all the trees in exactly the same condition. Previously, I have dealt with early-blossoming varieties first and the rest later. This adds so much to the time and work involved that I am now spraying all varieties at the same time. This year they are more level in development than usual, Worcester Pearmain and Lane's Prince Albert being little behind Beauty of Bath.

The making of Bordeaux mixture with hydrated lime is proving a much easier matter than with quicklime, and the stuff is so fine that there is hardly any blocking of nozzles. The slaking of lime on a large scale is a heavy business; and I hope that the Bordeaux mixture made with hydrated lime will prove equally effective, so that quicklime will never have to be used again.

There has been some difficulty in getting water for spraying some of the plantations, a new experience so early in the season. Most of the plantations can be sprayed direct from ponds or streams, but for some, water had to be carted a long way, and it was a struggle to get it delivered quickly enough. With four nozzles we have been spraying about four acres of fairly large trees per day.

The only insect damage to be seen on Apples after the winter spraying with tar distillate is an unusual type of injury done, I am told, by the Apple blossom weevil. This takes the form of piercing and lacerating of the young leaves surrounding the blooms, work which the weevils do at night. The same damage has been noted in Kent; and I am told that, in a previous season when this pest behaved in the same way, there was less than usual of the ordinary harm caused by this insect—the "capping" and destruction of bloom buds.

Spray Injury.

A conference of research workers and fruit-growers held recently at the East Malling Research Station did not bring to light anything definite about spray injury. Apparently there is at present no spraying programme which can be depended upon to control Apple scab without some risk of doing a little harm. It is a matter which depends very much on weather conditions at the time of spraying. It is very desirable that this risk should be removed, because there are many growers who are unwilling to do a little harm in order to do a great deal of good, and consequently will not spray at all. One hopeful fact brought out at the conference was the report that the addition of a small quantity of aluminium sulphate to lime-sulphur has given good results in Canada in preventing the leaf injury and fruit dropping which lime-sulphur alone sometimes causes. This will no doubt be tried by research workers in this country. The only drawback is that one cannot add the usual lead arsenate, but must use instead calcium arsenate.

I think that rather more might be tried in the way of dilute fungicides. A good many of us now use lime-sulphur as weak as one part in one hundred on sensitive varieties. It was mentioned at the conference that one part in 150 did no harm, but gave a poor control of scab; so it is probably unwise to go beyond one in one hundred. In the case of Bordeaux mixture, it has been usual to try the addition of various quantities of excess lime in order to render the wash less harmful, but little has been done in the way of diluting with an extra amount of water. This was tried, however, in some trials carried out last year in the eastern counties by Messrs. Petherbridge, Dillon, Weston, and Kent. A half-strength excess-lime Bordeaux mixture containing only 1½ lb. of copper sulphate and 5 lb. of quicklime to forty gallons of water, gave results little inferior to those obtained with a normal excess-lime formula giving double the amount of the two chemicals. Spraying was done three times, once just before blossoming and twice afterwards. The half-strength Bordeaux mixture gave a decidedly better control than lime-sulphur at one part in thirty before blossoming and one in sixty after. Even with such a weak mixture, however, there was a little russetting of the fruits of Worcester Pearmain, a variety not easily injured by fungicides. I am trying this half-strength Bordeaux mixture this year as a pre-blossom spray for Cox's Orange Pippin; but I dare not use Bordeaux mixture at all after blossoming.

Very dilute washes have been tried in America, notably at the Ohio Experiment Station. Bordeaux mixtures in which the copper sulphate varied from ½ lb. to 3 lb. in fifty gallons of wash gave results as nearly uniform as if the same strength had been used on all the plots. It is evident, therefore, that we might go further than we have done in the diluting of Bordeaux mixture in the search for a safe and efficient wash.

Dry Spraying.

Partly owing to the risk of doing harm by spraying, and still more because of the heavy work of wet spraying and the difficulty of getting over the ground quickly enough to catch the trees at the right stage, some growers are again taking an interest in dry spraying, or dusting. This costs more for material than liquid spraying, but very much less for labour; and it is done so rapidly with the larger machines that the trees can be treated at more frequent intervals. For dealing with certain insect pests the method has already given satisfaction to some of those who have tried it. The dusting of Gooseberries for the prevention of American mildew has also given good results. As a means of controlling scab, however, it has yet to prove its value in this country. In some countries abroad it is used in preference to wet spraying, in others not, from which it may be assumed that the result varies with the prevailing climatic conditions. Apparently, efficient work in dusting depends even more on the weather than in wet spraying. Wind is quite fatal to good work. For copper-lime dusts to act well it is necessary that the trees should be wet when the material is applied, and for sulphur dusts it is desirable that warm, dry weather should prevail. Although, theoretically, an exceedingly fine dust should be as difficult as the deposit from a liquid fungicide to wash off by rain, with the materials at present available the effect is not so lasting. The practice abroad seems to be to dust afresh after every rainy period. The hope that dusting would be less harmful may not be well founded, for it is stated that sulphur dusts are quite capable of causing loss of foliage and fruits. *Market Grower.*

VEGETABLE GARDEN.

A NEW VEGETABLE!

For those who live in sunny climes and are in search of a new sensation, I would recommend them to try the young flowering shoots of Yucca gloriosa, cut at the stage when they look like giant Asparagus. I heard that some acquaintances who were held up last year in the wilds of Texas where Yuccas grow wild in profusion, were reduced to cooking and eating them, and found them excellent. So this spring when the Yuccas here began to produce their flower spikes, and knowing that I should not see them in full beauty before leaving this coast, I cut and cooked some spikes. "Cook," of course, objected, but when the dish of "Giant Asparagus" came to table it was pronounced a decided success. There is a decidedly bitter taste, much like that of blanched Batavian Endive, but when stewed and treated like blanched Endive it is a striking addition to the menu, and is both wholesome and enjoyable, succeeding the Asparagus now past. I can confidently recommend it to those who have a sufficient quantity of Yuccas at hand. I could fancy that a wild, rocky valley planted with Yuccas might, in good hands, prove a real success and add a new dish to our menus. *E. H. Woodall, La Selva, Nice.*

HOME CORRESPONDENCE.

Paeonia Cambessedesii.—I send herewith a photograph of Paeonia Cambessedesii that may interest your readers (Fig. 185). It represents a young plant flowering for the first time, showing the flower fully expanded after bright sunshine. This, and older plants which flowered last year, were collected as seedlings in Majorca some years ago. As they have been grown entirely in the open and have come safely through this last winter, one may hope that they are becoming established, and will in time make large plants. The foliage is particularly attractive and the flower graceful, besides having a distinctly "old Cottage Rose" fragrance. The flower illustrated has set seeds. *A. D., Dorset.*

Manuring Arable Land.—Replying to *C. de B.*, regarding the manuring of arable land (p. 314), I have made enquiries in this neighbourhood—mostly light, sandy soil—and find that twenty-two tons, or even twenty-four tons, of manure is not an unusual dressing for Mangolds; in fact, I have seen this amount used on an estate near by. The method used is ridging the ground, placing the manure in the bottom of the trenches, and covering it by splitting the ridges with a ridging plough. If well-rotted, heavy farmyard manure is used, there is no difficulty in covering it, but in the event of the manure being in a greener state, it would be necessary to tread it in the furrow. I do not think it possible to directly plough in this quantity, and as is well-known, if manure is not well covered, it dries up very quickly and loses its value. I consider it should be spread and covered the same day, especially at this time of the year. I cannot help observing that most gardeners would be very pleased to have this quantity of manure available in these days of motors. *J. P., Worcester.*

Partial Soil Sterilisation.—Mr. Shewell-Cooper having thought fit to reopen the discussion on the above subject, I think it only fair to state on behalf of those of your readers he has labelled "incredulous," that I have received letters from interested growers and research workers strongly advocating steaming in preference to baking. One letter is from a departmental head of a very large firm of retail commercial growers, in which he states that his firm found themselves compelled to take up the question of soil sterilisation some thirty years ago, and since then they have spent very large sums of money testing every known device, including the erection of a large "baking" plant, and they have come to the conclusion that "steam sterilisation is the only practical method where soil is wanted in bulk, as is the case with us." Moreover, in your contemporary, *The Fruit Grower*, dated May 2, a Channel Islands correspondent states—under the heading "Dr. Bewley's visit—Glasshouse Problems," that two hundred growers were gathered together to hear Dr. Bewley's latest findings concerning the cultivation of the Tomato, and the following sentence occurs in his notes: "Another point impressed upon us was that there was nothing like steam sterilisation of the soil. The claims of several proprietary sterilisers were mentioned and explained, but at rock bottom there was nothing quite so good as the steam sterilisation." This is from men who are daily "delivering the goods," so what better testimony do we need, notwithstanding Mr. Shewell-Cooper's accusation of incredulity. *T. A. Summerfield, Chelford.*

Salix lanata var. Stuartii.—In reply to Mr. J. Fraser (p. 283), it was not my intention (p. 231) to introduce another Willow in an endeavour to establish the identity of the plant Salix lanata var. Stuartii. I make no pretence at recognising a plant which, so far as I know, I have never seen. On reading (p. 159) that the Wisley plant was named after Dr. Stuart, Chirnside, N.B. (this was Dr. Charles Stuart, M.D., with whom the Violettas originated in 1887), and reading (p. 107) that it could not be found in any book, and failing myself to find any support for the name S. lanata var. Stuartii, or record of a Willow having been named after Dr. Charles Stuart, in spite of diligent search, the possibility occurred to me that someone, trusting to memory, had made a mistake. Hence my reason for giving the dedication of a plant to the Rev. Dr. John Stuart of Luss, Dumbartonshire, by the greatest of all Salicologists, Sir J. E. Smith, then President of the Linnean Society, so long ago as the first edition of *Eng. Bot.* This dedication should have priority over any other, if there were one. My reason for writing "should the plant prove to be this hybrid from Aberdeenshire," and expressing the hope that it would receive an authentic name, is—one is a hybrid, while the other is given as a variety. *J. Blades, University Botanic Garden, Cambridge.*

The Sweetest-scented Flower.—In consequence of a recent debate with a friend, I would like to hear the opinions of your readers, as to what popular plant or flower they consider has the sweetest scent. Of course, as we found, this opens up a tremendous field for argument. Naturally, different people hold different views, and unless a person is specially keen on any one subject, he will find it hard to name a favourite. Personally, I think the Lily-of-the-Valley would head the poll, but the vine, when in flower, is a serious rival. Violets, Roses, Stocks, Lilacs, Wallflowers, Primroses, Sweet Peas, Genistas, Lupins, Hyacinths and Narcissi, to quote but a few, all have claims. No doubt this subject has been discussed times without number, and I would be interested to know what decisions were arrived at. *R. Kemp.*

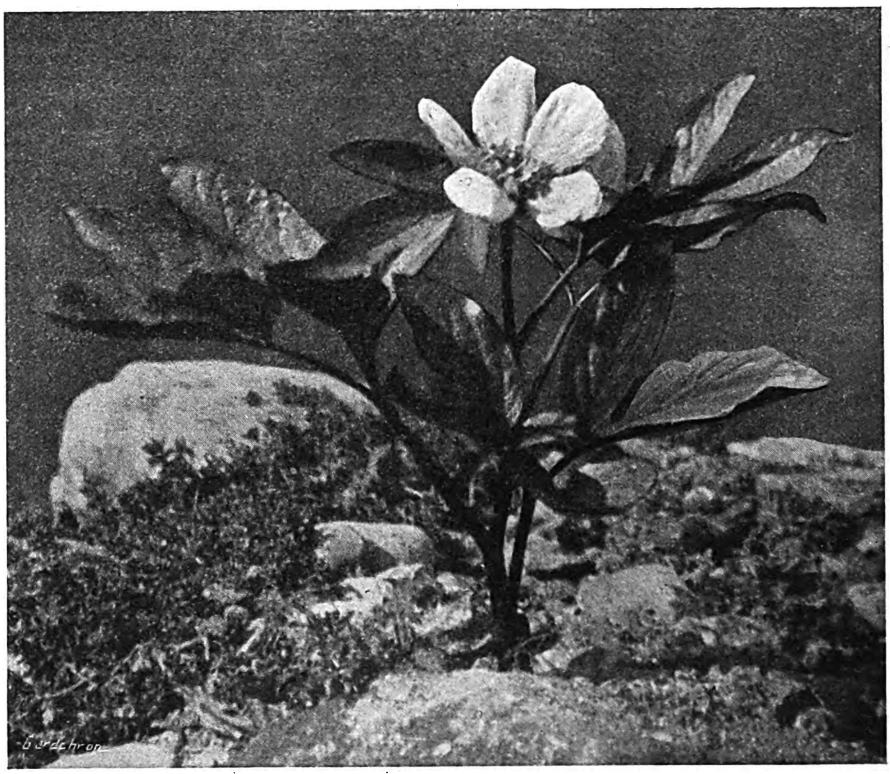

FIG. 185.—PAEONIA CAMBESSEDESII.

FOREIGN CORRESPONDENCE.

BAECKEA FRUTESCENS.

THIS graceful, evergreen Myrtaceous tree with Heath-like flowers and foliage, is found at altitudes of 3,000 to 5,000 feet, in the Malay Peninsula. The branches are wiry and droop after the fashion of a Weeping Willow. The leaves are about half-an-inch long, very narrow and acute, and the small flowers, borne on short pedicels, are white, with a green ring in the centre.

The dried leaves of this subject are stated to contain properties useful for the treatment of fever, and for this purpose they are sold in the Malayan markets.

B. frutescens appears to succeed in all types of soil, so long as it is of an open nature, and propagation is effected by seeds, cuttings or suckers. *F. S. Banfield, F.L.S., Malaya.*

ROSA GIGANTEA.

APROPOS of the flowering of Rosa gigantea at Cambridge Botanic Garden (p. 288), I well remember having seen this Rose in flower in 1916, but somewhat later in the season, I believe. Three buds opened then, and the large flowers, not unlike those of the cultivated single variety, Mrs. Oakley Fisher, but of a paler shade of colour, developed towards mid-day a faint honey scent.

As one who had the privilege to work in the various departments of this large and well-kept garden under the direction of the much esteemed Mr. R. Irwin Lynch, V.M.H., I cannot fail to be interested in what happens there, as was the case some time ago with the flowering of Clusia grandiflora. *A. R. Lugeon, Morges, Switzerland.*

PUDLIC PARKS AND GARDENS.

MERTON and Morden Urban District Council has decided to buy, for £6,000, sixteen acres of the Ravensbury Manor Estate, a stretch of pasture and woodland on the banks of the River Wandle, to preserve it from the builder. Ravensbury Manor was recently sold for building purposes. The land purchased by the Council will continue the green belt formed by the Watermeads, the National Trust Property which it adjoins. The Council expects to secure a substantial contribution from the Mitcham Council, in whose area most of the estate lies, and also from national bodies.

THE Middlesex County Council has agreed to contribute £1,490 towards the cost of the acquisition by the Wealdstone Urban District Council of land at Kenton for an open space.

BRIGHTON Town Council proposes to spend £5,000 on converting The Level, a large open space in the centre of the town, into a playing ground for the poor children who live in the district. A large boating pool is included in the scheme.

SOCIETIES.

CARDIFF GARDENERS'.

The first of the monthly Saturday afternoon outings of this Society took place on May 4, when a large number of members visited The Cottrells, the beautiful residence of The Mackintosh of Mackintosh, which stands amid lovely surroundings in the Vale of Glamorgan. The party was conducted around the gardens by the gardener, Mr. G. Thompson, who spared no effort in pointing out the chief features in the various departments. Many losses as a result of the severe winter were noted. Some of the Magnolias, however, were very striking, and the Daffodils also called for admiration for, although many were past their best, there were plenty to hold the interest of the members for some considerable time.

In the kitchen and fruit gardens everything, although backward, looked promising and well cared for. In the glasshouses there was a great deal to attract attention, a magnificent collection of Schizanthuses being much admired. Many of the old-fashioned stove and other greenhouse plants, now uncommon, were found to be flourishing under the care of Mr. Thompson and his staff. Although Grapes are not grown at The Cottrells, there were plenty of Peach and Nectarine trees under glass, all carrying excellent crops of fruits.

At the close of the visit, Mr. J. E. Turner, J.P., a Vice-President of the Association, proposed a hearty vote of thanks to The Mackintosh of Mackintosh, and also to Mr. Thompson.

PARKS AND BOTANIC GARDENS SUPERINTENDENTS.

The first Annual Meeting of the North-western Branch of the Association of Parks and Botanic Gardens Superintendents was held in the Town Hall, Manchester, in late April, and was attended by over thirty members from various towns in the district. Mr. M. Morgan (Crewe) occupied the chair, and an apology for absence, owing to indisposition, was received from the President of the Association, Mr. W. W. Pettigrew. The Branch Secretary's report of the proceedings covering the period since the formation of the Branch in November, 1927, and which had been circulated to all the members previous to the meeting, was approved and adopted.

The Chairman, in his address, eulogised the work of the President and General Secretary of the Association in connection with the formation and progress of the branch, and stated that the measure of success attained had been largely due to their efforts. Mr. M. Morgan was unanimously re-elected Chairman for the ensuing year, and Mr. J. Richardson (Salford) was elected Branch Secretary.

The following members were appointed to serve on the Committee, :—Mr. T. Bent (Bolton), Mr. E. Winsor (Blackburn), Mr. S. Turner (Stalybridge), Mr. G. Mottram (Oldham), Messrs. J. J. Graham and J. J. Mackintosh (Manchester), and Mr. J. Holland (Chadderton).

On the invitation of Mr. Winsor, it was decided that arrangements be made for the members to visit several of the Blackburn Parks on September 14 next.

At the conclusion of the Annual Meeting, Mr. H. Abbott, Forestry Adviser to the Burnley Corporation, read a very interesting and instructive paper on "The Aesthetic Value of Trees." He urged the planting of trees in towns whenever possible, and emphasised the importance of removing dead and decaying branches from old trees, so as to prevent the spreading of fungus diseases to healthy specimens growing in the vicinity. He gave a very lucid description of the valuable work which had been carried out under his supervision at Towneley Park, Burnley, in the renovation of old trees.

He is of the opinion that public parks should be utilised to a greater extent for the planting and labelling of trees suitable to the neighbourhood, for the guidance of the citizens as to the best kinds to plant in their gardens. He also pointed out the value of trees planted in various positions; even scrubby trees growing on exposed positions have a great aesthetic value; and advocated that a free use should be made of trees in public parks for blotting out views of unsightly buildings. Trees to be planted near old mansions in parks should be in keeping with their surroundings.

Mr. Abbott emphasised the importance of allowing sufficient space between individual trees when planting an avenue, as the effect was often spoiled when the trees had been planted too closely together. Where special effects are desired, the planting scheme should receive careful consideration so that the effects be spread over so long a season as possible. He also described the methods adopted in continental nurseries in preparing standard trees for street and avenue planting.

Several members joined in the discussion after the lecture, and a vote of thanks was unanimously accorded to Mr. Abbott.

ANSWERS TO CORRESPONDENTS.

Beetroots Blackened.—*M. L. M.* The Beetroots are infected with the fungus Phoma betae, which causes heart-rot in Beet. The fungus passes from the foliage to the roots. The first symptom of attack is the premature wilting of foliage during August. All leaves showing signs of wilting at that season should be pulled off and burnt, before the fungus gains an entrance into the roots through the petioles. All affected roots should be burned on the hot ashes of a garden fire, or buried deeply, and should not be allowed to remain on the rubbish heap.

Carnations Diseased.—*J. M. P.* The Carnation foliage is affected by leaf-spot disease due to Septoria dianthi. Cut away and burn all dead shoots and remove foliage which shows any sign of black spots. Spray the plants with Bordeaux mixture, or dust them with green sulphur when the foliage is moist with dew.

Cockchafer Grub in Soil.—The grub sent for identification was the larva of the cockchafer, or Maybug, Melolontha vulgaris. It is a common pest in gardens, the larvae feeding voraciously on roots of most plants. When digging the soil, remove and destroy any of these grubs that are found.

Melon Diseased.—*A. T.* The Melon plant is infected by Verticillium wilt disease. The incidence of attack is increased by low and sudden falls in temperature and cold conditions of the border. Raising the temperature to above 75°, regulating the amount of air, closing down the house for about three hours in the middle of the day and reducing the amount of water in the borders, will tend to check the disease.

Name of Fruit.—*F. W. M.* Apple Annie Elizabeth.

Name of Plant.—*T. R.* Amelanchier canadensis.

Peaches Setting Badly.—*A. H.* We might have helped you more had you given detailed information in regard to the temperature maintained day and night in your Peach house up to the time of flowering and during that stage. A temperature ranging from 43° to 48° at night up to the time the trees come into bloom, is quite high enough, with 48° to 50° at night when in bloom, and 55° to 60° during bright, sunny days, with plenty of ventilation. Bees are undoubtedly good fertilisers, but should the weather be unfavourable, then artificial means should be adopted by lightly brushing over the flowers at noon with a rabbit's tail or camel-hair brush. The atmosphere should also be kept dry when the Peaches are in bloom, and the house should be freely ventilated on all favourable occasions, allowing a current of air at night if possible.

Softening Hard Water.—*P. E. K.* At least two methods for softening hard water are known. Some water holds salts of magnesia in solution. This will decompose common soap and form an insoluble stearite of lime or magnesia. This is not likely to be used for domestic purposes. Water that is made hard by carbonate of lime in solution can be softened by the addition of lime (CaO) suspended in the water in such quantity as to neutralise the carbonic acid, and the new combination is precipitated or falls to the bottom of the vessel as sediment, which is presumably separated from the clear water. This method is often adopted on a large scale in connection with reservoirs of water for drinking and domestic purposes generally. Such water could in no way be harmful to pot plants; indeed, it should be better for Heaths, Rhododendrons, Azaleas, etc., than hard water.

The House Fly.—*G. H. B.* Fumigants are not often used in dwelling-houses, although we have known sulphur to be burned for a variety of purposes, and we think it is worse than most or any of the fumigants used, since it will turn white woollen goods, such as flannel, of a yellowish hue. Any such in a room could be removed before fumigating it. We do not think there would be any discoloration of woodwork, paint or goods by vapourising XI All Nicotine insecticide in the house. This is done by placing some liquid or Nicotine cake in a saucer, supported by something, so that a spirit lamp could be placed under it and lighted. Doors and windows should be closed, and a wet cloth placed at the foot of any door to prevent the fumes from going into other rooms, if necessary. The smell of Nicotine might be considered disagreeable by some people; to us it is pleasant. After it has been kept in a house or room for two or three hours it can be dispelled by ventilation. To abate the nuisance of the house fly, it is important to keep the garden and surrounding of the house free from heaps of decaying vegetation, manure and other rubbish, in which the eggs of flies are hatched. Waste from the kitchen should be placed well away from the house.

Tulip Bulbs Diseased.—*D. H.* The Tulip bulbs you sent show severe infection with the disease known as Botrytis tulipae, which would appear to be becoming a serious menace to Tulips. For treatment, see a note on the same subject in our issue of April 13 (p. 286).

Tomato Plants Scorched.—*J. B.* The Tomato foliage shows signs of "scorch" due to the harmful fumes from the heating apparatus. There is no sign of damage by fungus. The tray of water surrounding the lamp is insufficient to eliminate the trouble, as the fumes are not absorbed by the water. Actively-growing plants are quickly damaged by the fumes from paraffin oil stoves.

Vines Mildewed.—*H. G.* The vine foliage is attacked by mildew caused by Oidium Tuckeri. Careful attention must be paid to ventilation so that all draughts are prevented; water the border with great care, particularly an outside border. Dust the foliage, after syringing, with green sulphur.

The Symbiosis between Nodule Organism and Leguminous Plant.

The broad facts of the relationship which subsists between the Leguminous plant and the "nodule organism" have long been known; and although custom is the victorious foe of admiration, the strangeness of the relationship between the green plant and the microbe must still impress the mind, unless it be most unimaginative, with wonder. The Leguminous plant grows like other green plants, from seed. The seedling, however, maintains its independent life for only a few days. Very soon it "takes up with" a bacterium which reaches it from the soil. The bacterium, settling on a root hair, increases in numbers with the prolificness common to bacteria, and the mass of descendants grows through the root hairs into the cortical cells of the root. There they take up their abode, stimulate the cells of the root to form irregular nodules or tubercles, and in their routine activities achieve what would seem impossible, namely, bring free nitrogen into combination with other elements—fix nitrogen, as we say—thereby making it available for the synthesis of proteins. Plant and microbe share the proceeds, although, needless to state, the Leguminous plant pays for the services rendered to it by its microbic lodger. From its ample store the Legume provides the nodule organism with sugar and mineral matter and receives in return proteins, or other organic nitrogen compounds. The fact, known since Roman times, that the crop following on a Legume benefits from the activity of its predecessor, received, with the discovery of the nodule organism and the infection of the Leguminous plant by that organism, a simple and sufficient explanation. But anyone who studies and reflects on the symbiotic relationship between Legume and nodule organism soon realises that there is much more to learn about it. Until recently, however, the study of the biological side of this symbiosis had not led to any very arresting conclusion. But now, the investigations of Mr. H. G. Thornton, of the Bacteriology Department of the Rothamsted Experimental Station,* have shed new light on this old problem. Mr. Thornton finds that the seedling Leguminous plant—he worked with Lucerne (Medicago sativa)—does not fall an inevitable victim to the nodule bacterium. For the first few days of seedling life the Lucerne plant, although growing in soil teeming with the nodule bacterium, remains uninfected. Not until it develops its first rough leaf does the seedling's immunity disappear. With the bursting of that leaf, however, a new chapter opens in the life of the Lucerne plant. Nodule bacteria settle down in its root hairs. Increasing rapidly, each bacterium forms a colony, the colony migrates by growing from the soil into the plant and henceforth lives and grows within that plant until death puts a term to the lodging and the lodger. Mr. Thornton naturally set himself to discover what this curious delay in infection should mean. He found that if young seedlings are grown with older ones—as evil communications corrupt good manners—so the presence of the elders leads to the precocious infection of the young. Hence, it would seem probable that with increasing age the Lucerne seedling excretes something from its root which attracts the nodule bacteria. Instead of growing freely through the soil, the bacterium settles down in the root hairs—that is the fatal step—the rest is easy. It grows into the plant and in so doing surrenders for ever its individual freedom. Experiments made with extracts of the soil-medium confirm the conclusion that the maturing root, at about the time the Lucerne plant is unfolding its first rough leaf, produces and excretes a substance which encourages rapid infection, and it may be supposed that were the plant not to produce this material, nitrogen fixing by the Leguminous plant would not take place; for, apparently, in the absence of this bait, the bacterial fish would not rise, and the Leguminous plant would be unable to land it!

Tomato Grading in Scotland.—After consultation with growers, and wholesale and retail traders, the Department of Agriculture for Scotland has prescribed grade designations to indicate the quality of Tomatos produced in Scotland in accordance with the provisions of the Agricultural Produce (Grading and Marketing) Act, 1928. The specifications of size and weight are as follows:—Large A.A., four to six fruits to 1 lb.; A.A., seven to nine; Medium A.A., ten to twelve; and Small A.A., thirteen to sixteen. Only one grade of Tomatos shall be packed in each package, and the fruits must be of the first quality—freshly picked and packed in sound condition, fully and uniformly coloured, round, smooth and unblemished. The Tomatos are to be packed in clean, sound, non-returnable, 12 lb. "chip" baskets, lined in the bottom with strong, dark blue paper, and on the sides with dark blue tissue paper. The grade designation mark is to consist of a map of Scotland in silhouette, bordered on the left by a design representing the Union Jack and on the right by a design representing the Cross of St. Andrew, and associated with the words "Produce of Scotland" and "Empire buying begins at home." The labels will vary in colour so as to clearly denote the grade to which they are applicable; thus the labels for Large A.A. will be white; for A.A., red; Medium A.A., blue; and Small A.A., yellow. The Department expresses the opinion that the adoption of the designations will assist Scottish growers, whosesalers and retailers, to market produce of such uniform quality as will lead to a substantial increase in the demand for Scottish Tomatos. The success of the scheme will largely depend on the confidence with which retailers will regard Scottish Tomatos sold under the National Mark.

Sodium chlorate as a Weed-killer.—The notes on the use of sodium chlorate as a weed-killer, in our issues for February 23 (p. 151), and April 20 (p. 298), have resulted in an interesting communication from Mr. Alfred Hill, B.Sc., of the Agricultural Chemistry Department, Marischal College, Aberdeen, who has also kindly sent us a reprint, from the *Scottish Journal of Agriculture*, Vol. XI, No. 2, April, 1928, of the report on trials of weed-killers on garden paths carried out at Craibstone, the Experimental Farm of the North of Scotland College of Agriculture. Mr. Hill points out that sodium chlorate was included in these trials since 1926 because, at about that time, proprietary weed-killers containing sodium chlorate as the active principle, were appearing on the market, although he believes that the substance had previously been applied with success on paths on the Continent, especially in Norway. At Craibstone, sodium chlorate, although it destroyed weeds growing on paths at the time of application, was found to encourage the growth of moss, and was therefore not recommended. On the other hand, copper sulphate proved very effective as a path weed-killer, provided the weather conditions at the time of, and following, the application were favourable.

Legacies to Gardeners.—The late Mr. I. Williams, of Wilderton, Branksome Park, Bournemouth, who died on March 5, left the sum of £500 to his gardener, Mr. John Caldwell, and £50 to his under-gardener, Mr. Arthur Foster, if respectively in his service at the time of his death. He also left instructions that the annuity of £40 to his former gardener, Mr. Jeremiah Best, be continued.—Mr. Obed C. Hawkes, of South Bank, Harborne Grove, Edgbaston, who died on February 10, left £100 to his gardener, Mr. J. T. Wrigley.

"The Gardeners Chronicle" Medal.—Our Medal, offered at the Cornwall Spring Flower Society's show, was won by Mr. James Allen, 35, River Street, Truro, for six kinds of hardy spring flowers.

Rhododendron Association's Year Book.—A floricultural association that is able to give its members a *Year Book* priced at 21s. is rather out of the ordinary, particularly as the publication is well worth the price, and admirably fulfils one of the objects of the Association, *i.e.*, "to encourage, improve and extend the study and cultivation of Rhododendrons by means of publications." This *Year Book* is of octavo size, strongly bound, and extends to no fewer than 163 pages. The "List of Rhododendron Species," prepared by the President, Mr. Lionel de Rothschild, is compiled from the garden point of view; the specific titles are explained, the series or sub-series is given, and the colour of the flowers; in the case of certain species some additional and useful information is added, such as height, habit, and degree of hardiness. Although based on Mr. Wilding's *Rhododendrons; Their Names and Addresses*—to which due indebtedness is acknowledged—it is a splendid piece of work, and extremely useful to shrub lovers in general, and Rhododendron lovers in particular. This is followed by a list of the "Series and Sub-series" in which botanists have arranged the various species, and a general description is given in each case, and this is made the more useful by the addition of a list of "Best species in every series and sub-series as known at present."

---

* "The Rôle of the Young Lucerne Plant in Determining the Infection of the Root by the Nodule-forming Bacteria," by H. G. Thornton. *Proceedings of the Royal Society*, Ser. B. Vol. 104, No. B732, April 6, 1929. Printed by Harrison and Sons, 44-47, St. Martin's Lane, London; price 5s.

In the latter part of the book there are valuable articles on “Hints on the planting of Hybrid Rhododendrons,” by Mr. F. Gomer Waterer; “The Rhododendron Show of 1928,” by Mr. G. H. Johnstone; “Rhododendron Growing in Lime,” by Major F. C. Stern, who gives the experience gained in his garden at Highdown, Goring-by-Sea; “Noteworthy Rhododendron Species,” by Mr. H. White; “Hybrid Rhododendrons,” by Mr. R. W. Wallace; and “New Hybrid Rhododendrons,” by Messrs. C. B. van Nes and Sons. The *Year Book* concludes with a “List of Hybrid Rhododendrons,” compiled from the lists of the principal nurserymen. This is also a valuable compilation as the colours of the flowers are given, and the degree of hardiness indicated, while the early flowering varieties are specified as such; moreover, new Rhododendrons and those of the older ones still worth growing are marked with a star, and those known to have particular merit have two or even three stars against them. An important observation is that “it is hoped to arrange either a trial of new Rhododendrons in order to judge of their particular merits, or get indications from various members of the Association who happen to have these growing in their gardens, and any suggestions on these points will be welcomed.” We congratulate the Rhododendron Association upon its initial publication in which such an exalted standard has been set that we wonder whether it will be maintained in future issues. The Secretary of the Rhododendron Association is Mr. Gurney Wilson, Royal Horticultural Society, Vincent Square, Westminster.

Scottish Crops Under Glass.—In accordance with a request from the Scottish Horticultural Advisory Committee, the Department of Agriculture for Scotland has taken steps to obtain detailed information in respect of the area and production of crops from under glass in Scotland in 1928. In the schedule which has been distributed, growers are requested to state the amount and value of each crop, such as Grapes, Peaches, Tomatos, Cucumbers, flowers and vegetables, etc., separately, and to give the quantities in weight, preferably in hundredweights, while the value should represent as nearly as possible the amount received for the crop in the wholesale market, or, if sold on the spot, the price on the premises.

Chrysanthemum Congress at Béziers.—The twenty-ninth annual Congress of the French Chrysanthemum Society will be held this year at Béziers, from November 5 to 9, and will coincide with an international horticultural exhibition jointly organised by the local Chrysanthemum and horticultural societies. A number of questions of practical application will be discussed at the Congress, the exhibition will come in for a full share of attention, and the remainder of the time available to the visitors will be occupied in social activities and in excursions to places of interest in the neighbourhood.

Difficulties of Scottish Forestry Commissioners.—Although much has been, and is being, done in the afforestation of Scotland, the public conscience has been incredibly slow to awaken to the potentialities the Forestry Commissioners have in view. They are finding the task mapped out for them a herculean one. The great difficulty—and it may be stated a leading one—is to make landowners' sentiment overcome their cupidity. The great obstacle to tree-planting, which has proved insurmountable in the past, is the knowledge that others must reap where we sow, and hence the resources that might be applied to afforestation are spent in other directions where the yield is quick and the returns lucrative. Would that the advice of the sagacious Duke of Atholl, given to his son, Jock, decades ago—“Aye, keep stickin' in a tree, Jock, it'll be growin' when ye're sleepin' ”—had been followed in past years, then, indeed, Scotland at this day would have been the possessor of a vastly greater amount of natural wealth in the form of trees than is now the case. Centuries ago, Scotland was finely wooded, with sturdy, healthy Pines growing to heights which they cannot reach to-day. Changes of climate and water-level, household and industrial requirements, and the inhabitants' destructiveness, have all taken their toll from, and practically blotted out, the ancient Caledonian forests, and this, too, in spite of preventive efforts made since the twelfth century. It required a Great War for the people of this country to realise the terrible inadequacy of their home timber supplies, but even yet it is to be feared the public conscience has not been thoroughly aroused to the gravity of the situation.

Mrs. A. Sherman Hoyt.—The lady to whose enthusiasm and enterprise the large exhibit of Cacti and Succulent Plants at Chelsea Show has been possible, has a long and close association with horticulture in America. The exhibit at Chelsea is described and illustrated in the present issue; this display of Californian desert plants is, however, not a prentice's effort, for Mrs. Sherman Hoyt had a large exhibit at the New York International Spring Show in 1928, which was awarded the International Gold Medal and the Special Gold Medal of the Garden Club of America, while the Tacoma Garden Club, the Seattle Garden Club, and the Pasadena Garden Club each awarded Mrs. Hoyt a Gold Medal. The exhibit was presented to the New York Botanic Garden at the conclusion of the show. Mrs. Hoyt's second effort was made in connection with the Boston Centennial Spring Show at Massachusetts, entirely at her own expense; this was in three parts—a Desert Garden, Death Valley and Redwood Trees, with suitable scene-painting backgrounds to secure the proper “atmosphere” and perspective. This big exhibit was awarded the Old English Cup for the most educational exhibit in the Show; the Pennsylvania Horticultural Society's Gold Medal and the Grand Centennial Gold Medal. The Chelsea exhibit is therefore the third of its kind arranged by Mrs. Sherman Hoyt, and it is the largest and most comprehensive of the three, as it includes the whole of the Boston exhibit with the addition of a further car-load of rare desert plants. Mrs. Sherman Hoyt's generosity extends beyond the arrangement of a unique and educational display at Chelsea Show, for she has presented the exhibit to the Royal Gardens, Kew, free of all cost. No such exhibit has ever before been placed before the public in this country. The lady is State Chairman (California) of the Conservation Committee of the Garden Club of America; one of the founders and first Vice-President of the Cactus and Succulent Plant Society of America; a Fellow of the Pacific Geographic Society; and a founder and one of the organisers and trustees of the California Botanic Gardens, at Manderville Canyon, Los Angeles. Mrs. Sherman Hoyt has no trade interests to serve, and her only reason for expending so much time, labour and money on the Chelsea Show display is that she loves the desert plants of California and desires to show them in as natural conditions as possible to people who cannot see them in the desert—she brings the desert to them.

MRS. A. SHERMAN HOYT.

The Journal of the Society of Foresters of Great Britain.—Foresters and students of silviculture will welcome the publication of Vol. III, No. 1, of *Forestry*, the official journal of the Society of Foresters of Great Britain. It commences with a report of the Third British Empire Forestry Conference, which opened in Perth, Western Australia, on August 22, and concluded at Auckland, New Zealand, on October 23, 1928. Two articles of especial interest are “The Multiple Mycorrhizas of Trees,” by Mr. M. C. Rayner, and “Oak Mildew and its control in Forest Nurseries,” by Messrs. R. C. Woodward, J. S. L. Waldie, and H. M. Steven, and the publication contains much data of general value to foresters.

Spring Flower Show at Rotterdam.—The spring Horticultural Exhibition took place at Rotterdam, Holland, on April 24 and following days, and in spite of the difficulties caused by the extreme lateness of the season, following a severe and protracted winter, the show was a great success. It was held in the large “Nenijto” hall, which amply accommodated the numerous exhibits, and permitted of a free and artistic style of display. The opening ceremony was favoured by the presence of the Burgomaster, Mr. P. D. Fortuyn, and other notable people, and the Queen-Mother of Holland visited the show on the second day. The Silver Medal given by the Queen was awarded to a very fine group of decorative flowers and plants arranged by Mr. G. J. Bier, Nieuwerkerk, while that of the Queen-Mother was won by a Belgian firm, Messrs. Theo. Pauwels, of Meirelbeke, with a display of Orchids.

East Malling's Research Station's Annual Report.—This splendid publication* reflects great credit upon the staff of the East Malling Research Station, for in it are chronicled the results of their labours and investigations for the year 1928; results of real value to fruit-growers, not only of Kent, but of the whole British Empire, for the work carried out at East Malling has resulted in placing the station in the front rank of British agricultural research stations. The *Report* is divided into three distinct sections:—(1) “General Development and Activities”; (2) “The Farm”; and (3) “Brief Progress Report of Investigations and Summaries for Fruit-growers.” Under Section 1, it is announced that visitors and enquiries from overseas have increased rapidly in numbers, and the number of contacts with home-growers is also increasing; no building was done during the year, and no new acquisition of land has taken place, although existing accommodation is taxed to the utmost. The preliminary work on the survey of the fruit soils in Kent has been commenced, while forty papers on various pomological subjects were published during 1928. The postal advisory work also increased last year, the total number of queries dealt with being 1,218, compared with 1,028 for 1927; the greatest increase was in relation to fungus and insect troubles. The Section devoted to the farm deals with the yields of fruits, and prices realised, which were apparently satisfactory, although the Pear crop, for the third year in succession, was a complete failure. But it is Section 3 which will attract the interest of most readers, for it contains detailed accounts of the investigational work. “The Effects of Various Fruit-growing Practices on Fruit Quality and Market Value,” is dealt with by Mr. R. G. Hatton, the Director; Mr. N. H. Grubb presents a summary of Apple pruning experiments conducted at East Malling over several years, and he also contributes an informative article on "The Effects of Potash Fertilisers on Apple Trees." Mr. J. Amos presents a classification of Red Currant varieties which should prove of great value, as it is founded upon the comprehensive collection got together at the Station, while the progress reports on root-stock investigations, fruit thinning, etc., are also very instructive. In the portion devoted to entomology are two contributions by Mr. A. M. Massee, on "The Fruit Tree Red Spider," and "The Black Currant Gall Mite on Red Currants," respectively, subjects which, last year, received his special attention. The publication should prove very helpful to commercial and private fruit-growers alike, and reflects great credit on all who are responsible for its production.

---

* *The Annual Report of the East Malling Research Station*, East Malling, Kent (April, 1929). Free to Associate Members; price to non-members, 3s. 6d., post free.

Rothamsted and Woburn Experimental Stations.—A cordial invitation is extended to horticultural and agricultural clubs and associations to inspect the experimental grounds at Rothamsted and Woburn during the coming summer. Mr. H. V. Garner, M.A. (Camb.), and Capt. E. H. Gregory will again be available for demonstration purposes, and the Director, Sir John Russell, will be pleased to arrange full details with organisations desirous of taking advantage of the invitation. If possible, arrangements for visits should be made beforehand, and requests should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden.

Muscari Heavenly Blue at Kew.—This lovely spring flower is very effectively planted in the Arboretum, at Kew, as a groundwork to several large beds and borders of deciduous shrubs. The most effective display is on the north-east slope of King William's Mound, where thousands of flower spikes produce a wonderful effect among the Hamamelis. This attractive Grape Hyacinth from Trebizond increases rapidly in cultivated ground, forming large tufts that produce freely spikes up to eight or nine inches high, well furnished with globular bells of rich gentian-blue. The flowers are pleasingly fragrant and in a cool season, such as the present, last for five or six weeks in flower. Perhaps the most important item in their successful cultivation is not to lift and dry off the bulbs for any length of time. Left in the ground after the leaves die off, the period of rest is limited to four or five weeks, after which the young leaves are seen pushing through the soil again. The best time for lifting, dividing and replanting is about mid-summer, when growth is complete, and the leaves are dying off.

The Grape-growing Industry at Hoeylaert.—Hoeylaert, situated at the edge of the Soignes Forest, near Brussels, is the centre of the largest Grape-growing industry in the world. It is not, however, very old-established, the first vines having been grown there by the three Sohie brothers, the eldest of whom is still living at Brussels. They established their nursery in 1866, when they constructed the first of the glasshouses which now cover many square miles of ground. Not only Grapes are grown at Hoeylaert. It was found that during the first few years of the life of the vine, the leaves were sparse enough to admit of the entrance of light into the house, and many other subjects could profitably be grown, such as early salads, Tomatos, Strawberries, Melons and Cucumbers. It is still customary to adopt this economical plan when new houses are established, and in some years these "catch crops" are productive of considerable profits. At the present day there are, in Hoeylaert itself, nine thousand glasshouses, and in the adjacent districts a further twelve thousand; each house is usually twenty yards long and seven or eight yards wide, the height being between two and three yards. It was not until 1870 that the houses were heated, but the system then adopted, known as the Flemish system, is largely in use still. The varieties of Grapes chiefly grown are Frankenthal, Gros Colmar, Alicante, Foster's White Seedling, Gros Doré, Royal Emile, Royal Molenberg, Gradisca and Muscat of Alexandria. Five-eighths of the Grapes are exported to England, the remainder being sent chiefly to Germany, Holland, America, Scandinavia, France, Austria, Denmark, Ireland, Italy and Switzerland. The exports increase each the amount in 1928 being nearly three year. kilos (roughly six million pounds). million

Southport Flower Show.—The Schedule of Classes and Prizes arranged for the sixth annual flower show at Southport has been issued, and copies may be obtained from Mr. T. E. Wolstenholme, Town Hall, Southport. Over £4,000 is offered in cash prizes, trophies and medals, consequently prospective competitors will understand that liberal awards are made to successful exhibitors. Two special features of the Southport Show—to be held in Victoria Park, on August 28, 29 and 30—will be the exhibition of the British Gladiolus Society, and the Sweet Pea Show to be arranged by the *Daily News* with the assistance of Mr. A. C. Bartlett.' There are seventy-four classes for Gladioli and thirty-one for Sweet Peas. The Schedule of the Southport Show includes nearly three hundred classes.

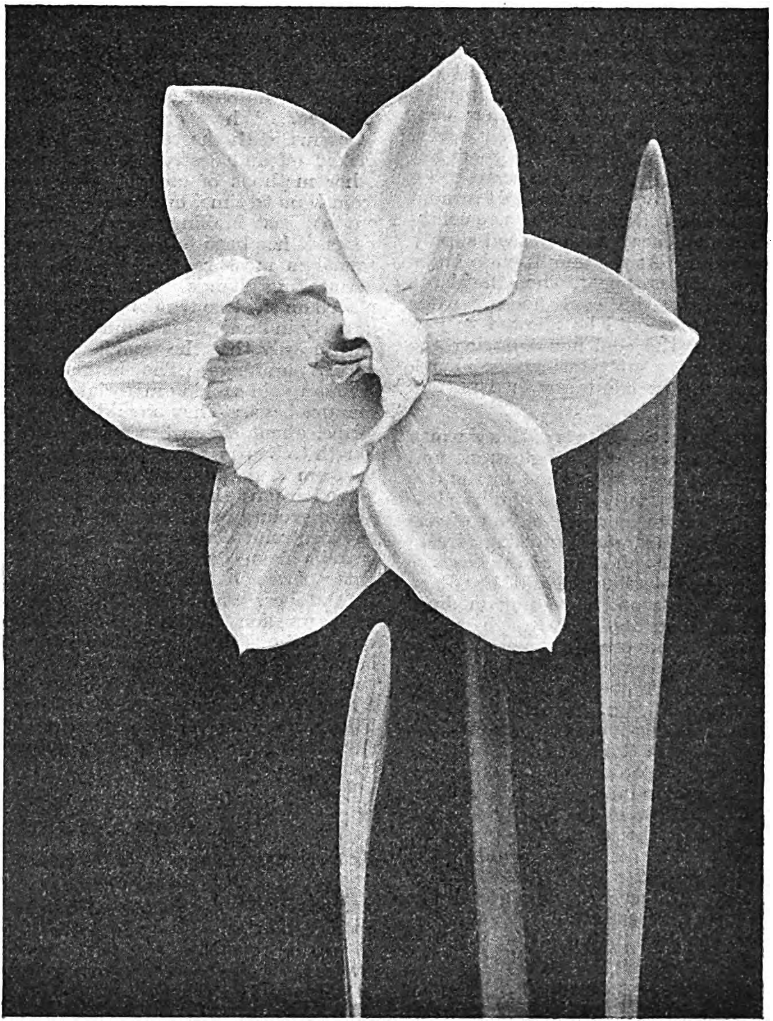

FIG. 186.—NARCISSUS MAY MOLONY.

R.H.S. Award of Merit, April 16; Award of Merit, Midland Daffodil Show, April 24. Flowers cream and primrose. Shown by Mr. Guy L. Wilson. (see pp. 300 and 334).

Early-flowering Chrysanthemum Trials.—The Horticultural Department of the Cheshire School of Agriculture, under the Superintendence of Mr. W. E. Shewell-Cooper, pays considerable attention to early-flowering Chrysanthemums. Last year, for instance, trials were carried out to test the effect of manuring, sterilisation of soil, and bacterized peat on Chrysanthemums. New varieties were also on trial, and a report thereon appeared in *The Gardeners' Chronicle* of February 9, p. 102. This year a trial of new outdoor-flowering varieties is being held and already there are over twenty new varieties entered for trial under typical northern conditions. If there are any growers who wish to include their new varieties or strains, they should send immediately not fewer than three plant of any one variety. The Horticultural Department is proposing to grow 8,000 plants in one trial or another. Further, this year a special series of trials is being held in the Baguley area, near Altrincham, on the flower farm of Mr. Harry Slerlock; thirty-two plots are being planned on the chequer-board system, and as the soil chosen is "poor," some definite results should accrue. The object is to find out some suitable substitute for the usual farmyard manure, as this fertiliser is becoming very scarce; 2,500 plants will be used in this trial. Visitors will be welcomed at both these trial grounds.

Appointments for the Ensuing Week.—TUESDAY, MAY 28: Royal West Renfrewshire Horticultural Society's show. SATURDAY, JUNE 1: Darwin and District Agricultural Association's exhibition; Leeds Paxton Society's Open Exhibition Night.

"Gardeners' Chronicle" Seventy-five Years Ago.—We beg to direct attention to the announcement in our advertising columns that in consequence of the Queen having been graciously pleased to name Saturday, June 10, as the day on which Her Majesty will open the Crystal Palace, the next meeting of the Horticultural Society at Chiswick, previously announced for the same day, will be held on Saturday, June 3, instead of Saturday, June 10. *Gard. Chron., May* 27, 1854.

Publications Received.—*Rock Gardens*, by A. Edwards; pp. 320, with eight coloured plates and other illustrations; Messrs. Ward Lock and Co., Ltd., Salisbury Square, E.C.4.; price 7s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Oncidium cheirophorum.—The new growths of this small, fragrant Oncidium, should now be well advanced. New roots are generally produced in quantity as the pseudo-bulbs begin to form, and just prior to this stage of growth is the best time for any necessary repotting, using well-drained pans and a compost of three parts A.1. fibre and one part chopped Sphagnum-moss; a little extra Sphagnum-moss may be used for surfacing. Damping off of the young growths after root disturbance may be avoided to a great extent if repotting is left until the growths are well-advanced, and if the plants, when potted, are placed under warmer conditions in the intermediate house for a few weeks, and watered very sparingly until the roots are well-established in the new compost, care being taken not to allow any moisture to collect around the pseudo-bulbs and growths. When re-established, the plants will need an increased supply of water at the roots. As the new pseudo-bulbs mature, the flower spikes appear, when the plants may be removed to the cool house. After flowering, the plants should be allowed to rest at the warm end of the cool house during the winter months, only sufficient water being afforded to keep the pseudo-bulbs in a normal condition.

Odontoglossum grande.—Plants of this warmth loving and large-flowered Odontoglossum, and of its varieties, that have been kept on the dry side since maturing their pseudo-bulbs last autumn, and are grown at the cool end of the intermediate house, are now growing freely and as new roots are just showing at the bases of the new growth, repotting should be done, using well-drained pots and a rooting medium of good Osmunda fibre, and a little Sphagnum-moss, which should be pressed firmly among the roots. Very little water will be needed until the flower scape is showing in the partly developed pseudo-bulb, but from this stage, provided the roots are active, ample supplies of water will be required at the roots each time the compost appears dry, in order to assist the plant to develop the pseudo-bulb and flower spike together. After the flowers are removed, every encouragement should be given the plants to assist the completion of the pseudo-bulb, a state generally reached a few weeks after the flowering period is over; when growth is complete drier conditions should be afforded, only sufficient moisture being given at rare intervals. Cultural conditions similar to the above are required by O. Insleayii and O. Schlieperianum. The plants should be examined for scale insects frequently, for these often attack this section of Odontoglossum and quickly spread from the pseudo-bulbs to the new growths, where considerable damage is done if the pests are allowed to remain; they should be washed off so soon as detected, using a small soft brush and sponge, and a weak insecticide. The foliage is easily damaged and disfigured if a strong solution of insecticide is used; unsightly spotting on the leaves will occur also if the plants are kept in a moist atmosphere and a low temperature.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

The Apple Blossom Weevil (Anthonomus pomorum).—The larvae of this insect causes considerable damage to the developing Apple blossom buds. The degree of damage depends very much, however, upon the weather conditions prevailing at the time of the blossoming of the tree. The pest is generally most destructive in cold and wet springs, when the blossom buds are long in opening, and not so severe when the weather is bright and open and the development of the buds more rapid. The larvae cannot live in an open blossom, and eggs are supposed to be rendered harmless by the expansion of the flower buds before they are hatched. Nearly the whole life cycle of this insect is spent upon, or near to, the tree. It is an adult weevil for eleven months, *i.e.*, from the June of the one year to the April or May of the next. The females, each of which is capable of laying from twenty to sixty eggs in as many blossoms, appear in April or May, select the most promising buds, and deposit a single egg in each, rarely more. These eggs hatch out in from five to seven days, and the grubs or larvae at once commence to feed upon the stamens of the flowers. The buds rarely open once the grubs have hatched, and the petals become brown and eventually dry up. The larvae change into chrysalids within the attacked blossoms, and at the end of about two weeks emerge as perfect weevils. For a short period the weevils feed upon the Apple foliage, but cause no serious damage, and finally they seek shelter until the following spring in cracks in the bark, or in rubbish at the base of the tree. Where practicable, all the attacked blossoms, with the tiny grubs inside, should be picked off and destroyed by burning. Various other methods of control have been advanced from time to time, but from experiments carried out at East Malling, Kent, over a number of years, it has been found that the Apple blossom weevil is most readily controlled by trapping in sacking bands. These bands should be placed on the tree trunks towards the end of May or early in June, as it is during the latter month and in July that the weevils seek shelter in the largest numbers. The bands may be made from any old sacking material such as discarded manure bags. They should be cut up into long strips, about six inches wide, each of sufficient length to be passed twice around the tree trunk to form a double thickness of sacking. It is placed around the stem at about eighteen inches above ground level, and tied once only at about the centre, to allow the free entrance of the weevils from above and below. The weevils enter these bands, which may be removed in October, when the weevils are in a state of hibernation. Where grease-banding is carried out, it should be concluded before the sacking is removed, so that should any weevils drop off the sacking they may be caught in the grease-bands on attempting to climb the tree again. The bands, with the weevils attached, should be subjected to boiling, as cold water has proved to be ineffective.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Spring Bedding Plants.—Those who practice spring bedding to any extent will now require to make provision for next season's display by sowing seeds of various plants required. Wallflowers, Myosotis alpestris var. Queen Victoria and M. a. var. Royal Blue should be sown towards the end of the month; Erysimums and Daisies in early June, also the various so-called winter-flowering Pansies. These may be had in distinct colours and come fairly true from seeds. Sow thinly and do not transplant the seedlings into rich ground, which is conducive to soft, flabby growth, and susceptibility to frost during winter. They should be grown in an open, airy, sunny position during summer, where they will make hard, sturdy plants. When good strains of Polyanthuses and Primroses are grown for spring bedding, it is often desirable to retain the best forms for future use, rather than depend on raising them annually from seeds. Where this method is practised the plants should be lifted immediately they are past their best, divided into single crowns and planted in nursery lines in a shady border, preferably with a northern aspect, where they can be kept moist and cool during the summer. Seedlings of Polyanthuses sown during February and pricked out in boxes, are now sufficiently advanced to be transferred to nursery lines; these, with good treatment, will make ideal plants by early autumn for furnishing the flower beds by the time the summer occupants are past their best. Other plants for the same purpose which may be increased by division this month, include many of the alpine Phloxes and the early-flowering Saxifrages. Of the former, the varieties Vivid and Sprite are very useful. They are easily increased by division immediately they pass out of bloom; cuttings also root freely if placed under a bell-glass or in a frame of sandy soil, in shade. These Phloxes flower later than many other spring flowering plants and, where used for carpeting, should only be planted in positions which will be the last required for summer bedding. Various mossy Saxifrages are useful for borders and edging, and should be lifted and divided so soon as they finish flowering; tufts of two or three green shoots will make nice plants by autumn if planted in nursery lines in a cool, moist soil. Aubrietias resent division at this season, and the better system is to have a reserve supply which can be divided in March for planting in their flowering quarters during autumn. The same applies to the double form of Arabis, but it may be increased readily by cuttings under a bell-glass; the pink Arabis known as Taplow Rose is an attractive plant of satisfactory colouring.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Forced Figs.—The first crop of Figs will now be ripe or approaching that stage, and syringing should be done sparingly, especially on dull days when a free circulation of fresh air cannot be maintained. Syringing, however, cannot be dispensed with entirely, as early Figs ripen in batches. The second crop is now well advanced and the fruits should be kept swelling by the aid of atmospheric moisture, fire-heat being necessary. A sharp watch must be kept on external conditions, and when the day promises to be fine, copious syringings of walls, stems and foliage, wherever this can be done without wetting the ripening fruits, should be practised. Afternoon syringing should be done cautiously, but every opportunity should always be grasped, after the ripe Figs have been picked, to syringe the plants. These remarks apply to light, well-ventilated houses, subject to aridity and red spider; shaded houses, where growth is strong may require much drier treatment. The supply of tepid water at the roots should be generous, and a fairly high temperature maintained, this being regulated by day and night ventilation. Shoots which have been tied back to let in light may be rearranged and possibly stopped, but it is not good practice, unless the shoots are gross, to stop them much in advance of the second crop, as the production of the first crop in the ensuing year depends much upon having growth tips thoroughly ripened.

Successional Fig Houses.—Trees started after the turn of the year will now come on quickly, and will withstand almost any amount of heat, with a proportionate supply of air and moisture. It is never wise to force growth too hard at night, especially when the Figs are in flower, but once this stage is passed, and if the roots are confined to warm, inside borders, a minimum of 70° will do them no harm. If trained on the long-shoot system, each growth should have plenty of room; the house should be syringed regularly twice on fine days, and once on dull days, for, much as the Fig likes moisture, the leaves should always become dry before nightfall. Every advantage should be taken to push the trees forward by early closing to trap the sun-heat in cold houses, where only one crop can be secured. So soon as early pot trees are cleared of their second crop, and if they are intended for forcing next season, they should be well fed with warm, diluted liquid manure in preference to being repotted, the main requirements being pot-bound balls of root fibres and abundance of short spurs showing embryo fruits. Some stopping will have been necessary to maintain a proper balance, but secondary growths will have plenty of time to ripen, especially if the roots are kept confined to the pots. They should be kept clean be copious syringings, and later, when summer heat prevails, plenty of fresh air should by admitted to ripen the young points.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Liliums.—Stem-rooting Lilies in pots will require close attention with regard to top-dressing, which, if not applied, will result in the plants being under nourished. The soil for top-dressing may be of slightly richer quality than that in which the bulbs were started, some well-decayed manure, passed through a fine sieve, being incorporated with it. To obtain the best results, avoid coddling the plants, but at the same time do not subject them to cold draughts. Liliums require an abundance of water during their growing season. Green fly should be watched for and checked so soon as it appears, or injury to the tips of the growths and the flower buds will result; to avoid this, spray periodically with a suitable insecticide.

Cinerarias.—Where it is desirable to have an early batch of Cinerarias the seeds should be sown without delay. Sow them thinly in well drained pans and stand the pans in a cool greenhouse. Cineraria seeds germinate very quickly; the young plants should be pricked off so soon as they can be handled and grown under the coolest conditions possible.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Salads.—To maintain a constant supply of Lettuces, Radishes, etc., during the early part of the season, it is absolutely necessary to have the aid of cold frames, but from now onwards most salads may be raised in the open. On light soils, and during the hottest part of the year, more satisfactory results will be obtained if the seeds of Lettuce are sown thinly so that thinning of the seedlings will be reduced to a minimum and transplanting dispensed with.

Thinning Seedlings.—Seedlings of Parsnips, Onions, Carrots, Beet, etc., should be thinned as each successive batch becomes sufficiently well developed, choosing showery weather for such work if possible. No hard and fast rule can be given respecting such work, as it is entirely a matter of thinning to suit the crop's and the grower's requirements.

Dwarf Beans.—A few rows of dwarf Beans may be sown, the varieties Canadian Wonder and Sutton's Prince being suitable, on a sunny border. The main sowing, however, should not be made until the end of the month or the first week in June; sow the seeds in rows eighteen inches apart and thin the seedlings to fourteen or eighteen inches from plant to plant; over-crowding should be guarded against as this hinders the development of the plants and results in the under-development of a great many pods.

Peas.—Early Peas which were started in boxes and transferred to the open border are now coming into flower, therefore they should be examined at intervals in case they become dry at the roots, when they should be soaked with water that has been warmed by exposure to the sun. Further sowings of maincrop varieties should be proceeded with.

Onions.—Hoe between the rows of Onions to destroy weeds and promote healthy growth. If plenty of cow manure is available, a mulching of that material should be applied along the rows in dry weather. Onions need plenty of moisture at the roots and they should be sprayed overhead if dry weather prevails during the evenings.

Runner Beans.—Where trenches for these were prepared some time ago, seeds may be sown directly into them. Seedlings from earlier sowings in boxes will now be ready for planting out-of-doors, if they have been hardened off thoroughly.

Brassicas. — Seedling Brussels Sprouts, Cabbages, Cauliflowers, and Kales, for early use are now well hardened and ready for planting in their permanent quarters. See that the ground receives a dressing of vaporite or sterolena, well worked in, before planting is done, to ward off the Cabbage fly larvae and leather jackets, which often prove troublesome, especially in dry seasons.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Regular sowings of salads, purple-topped and white Turnips, should be made. Swede Turnips should also be sown at an early date, in the most open and airy part of the garden and allowed plenty of room, twenty-four inches at least, between the rows. Thin the seedlings when large enough to twelve inches apart in the rows. These are subject to attack by what is known as the Turnip fly, but frequent dustings with dry soot will prevent this trouble, and as the attacks occur at an early stage, means should be taken to guard against them. Thin Asparagus seedlings in the permanent beds to six inches, and at a later date to at least twelve inches. Onions, if sown as suggested earlier, should not require thinning, but if they were sown thickly they should be carefully thinned so soon as possible; the practice of leaving them until large enough for use in salads, etc., has nothing to recommend it, especially where Onion fly is troublesome, and a separate batch of Onions should be grown specially for the production of such produce. After disturbance, such as occasioned by thinning, sheep dip, naphthalene or any other approved specific should be applied to ward off the Onion fly.

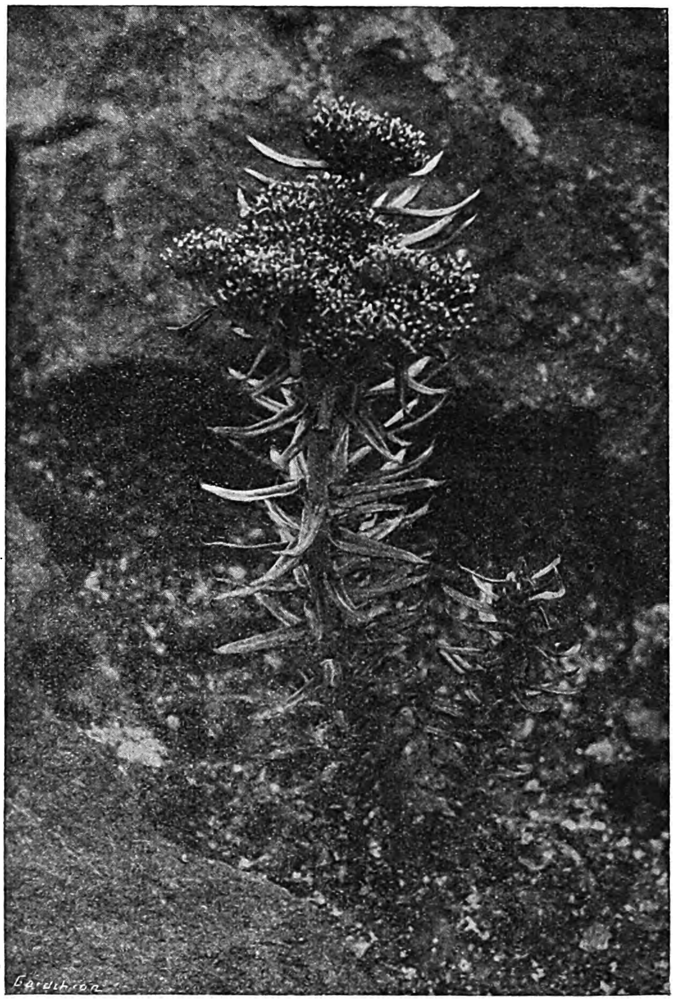

FIG. 187.—SEDUM KIRILOWII VAR. RUBRUM.
(see p. 379).

Strawberries.—Where mulching with short litter has not been carried out, the beds should now be dressed with straw or dried grass before the fruits swell so that they are prevented from coming into contact with the ground; all weeds should be carefully removed and the ground levelled with a Dutch hoe before applying the mulch.

Cherries.—After having set their fruits, the trees should receive a thorough drenching to wash away all unset fruits, and should black fly make its appearance on the tips of the young shoots, spray at once with orchard spray fluid or another approved wash. Apply a dressing of artificial manure and water it in well, or give a good soaking with manure water when the ground is wet, during, or immediately after, rain. Stop all unwanted growths at the fifth leaf.

Nerines.—These subjects having now finished growth, water should be withheld entirely, and the plants placed in a frame or house in full sunshine so that the bulbs may become thoroughly ripened; this treatment should continue until the flower spikes appear.

Herbaceous Plants.—These are now growing rapidly, and should be loosely, but securely secured to stakes, removing all weakly shoots and leaving the centres of the clumps open. Hoe around the plants frequently and, as the early-flowering subjects, such as Polyanthuses, Primroses, Auriculas, Pulmonarias, etc., pass out of flower, lift and divide them, and then replant in fresh soil.

NOTES FROM A WELSH GARDEN.

Although spring is a comparatively colourless season by the waterside, several bog, or semi-bog, plants were in flower before mid-May. The excellent Primula involucrata followed closely on the heels of P. rosea. Then came P. chionantha, very distinguished with its marble-white flowers and pale yellow buds in a setting of almost black sepals, the whole being dusted with a golden meal. Another white-flowered plant, at the edge of the water, is Caltha rotundifolia, whose many-rayed, star-like blossoms rival those of a colony of Sanguinaria canadensis glittering on rather higher ground close by. Also in moist, but not wet, soil, is a brace of interesting, dwarf Ericaceous shrubs, Phyllodoce coerulea and Cassiope Mertensiana, both in flower. That pretty weed, Rubus arcticus, is rambling about with quantities of bright rosy blossoms where Gentian verna is showing the first of its blooms. Some Dodecatheons have fired one or two early rockets here, and the fresh rose-pink flower clusters of Androsace geraniifolia are cropping up to remind one that this particular "mother of thousands" will not relax its determination to possess the earth until the last days of autumn. Nevertheless, this is an engaging and cheerful little sinner, and it affords a bright example to the half-hearted A. carnea var. Laggeri, hard-by, whose dark cushions were never more than feebly studded with its yellow-eyed, pink flowers. Contrary to expectations, Parochetus communis came through the winter so well in the cool, moist soil near the water that by the first week of May it had not only covered its sapless-looking stems with fresh green, but had produced several blooms. This, of course, means that we shall have an unbroken succession of these brilliant, gentian-blue Pea-flowers for a full six months.

The most notable occupant of this well-raised waterside bank is a Saxifrage that was sent to me by Sir Herbert Maxwell and named Monreith Seedling. The foliage of this fine plant somewhat resembles that of S. bathoniensis, the leaves being rather more finely cut. The stems, which attain the height of one foot, are very sturdy and a deep blood-red. Each of these bears about a dozen blooms which, a vivid ruby in the bud, open to a rose-pink, rich and vivid. The first flowers are nearly an inch across, and their striking colour is accentuated by an eye and veining of bright crimson. The generous donor would be able to give a more accurate colour description than I have done of this very attractive Saxifrage. It is a plant that stands out with singular distinction in an average amateur's collection of its class, and its colour is of an unusually fast dye.

In the rock garden a very choice little Crucifer with flowers of a singularly rich and vivid yellow, on one-inch stems, bears the name of Erysimum gelidum, and I believe it is Mr. Ingwersen whom I have to thank for this dainty gem. Rivalling this in the intensity of its yellow, as well as in the diminutiveness of its stature, is that elfish atom, Viola biflora. V. cucullata var. alba is such a fine and hardy plant, and so free with its big, white flowers, that with me it always excels over the type. Veronica peduncularis, although one of the earliest of the Speedwells to flower, is practically an all-season plant, producing a multitude of pearly blossoms on six-inch sprays. It is soon followed by the familiar V. Teucrium var. dubia (prostrata) which, good as it is in all its forms, reaches its highest pitch of excellence in the Benjamin of the tribe, the adorable little V. T. var. d. nana. The latter may not be this treasure's legitimate name, and I suspect that the "alpinas" and "compactas" of the lists are all the same thing with, perhaps (who knows ?), a better claim to specific rank than some plants of that exalted plane.

Aquilegia flabellata, a diminutive form with nearly pure white flowers, is a little Columbine of much quality, the first of its race to flower this season. Some of the survivors among Primula Forrestii were in bloom before the middle of the month, and in the arid, stony soil, favoured by that well-bred but squeamish species, both Erodiums and Androsaces of the woolly sorts are doing uncommonly well. A sunny spring has also suited Daphne petraea, the wee bush carrying some thirty or forty of its exquisite blossoms. That charming plant, Polygala calcarea, is another which is expressing its approval of weather conditions. As for P. Vayredae, its crimson and yellow blooms have not been so brilliant a colour, nor yielded in such quantity, for many a day. Potetillan rupestris, rare as a native, looks very stately on the top of a dry retaining wall, its beautiful foliage and erect, honey-coloured stems of eighteen inches being surrounded by elegant flights of white flowers. Its microscopic Corsican representative, P. r. var. pygmaea, is not less charming in its own way. On a close-up ledge of meagre, stony soil, Armeria caespitosa is also very choice among the Lilliputs. This is not a plant easily wintered here, with the result that A. caespitosa × A. alpina seedlings of chosen colour often have to do the part of understudy for the real thing. Alyssum atlanticum is a silvery-leaved, yet hardy, trailer, with large, round clusters of rich yellow blooms of unusual substance, and from the same region comes Geranium atlanticum, its stiff, ten-inch stems terminating in heads of nodding, violet bells. Saxifraga Maweana I had for some years, but it was ever on the doubtful list. Since its departure, S. Wallacei has reigned in its stead, and it is questionable whether this fine hybrid of unknown origin has ever been excelled in its own colour. White-flowered mossy Saxifrages of imposing stature and distinguished for the amplitude of their blooms and general heartiness we have in plenty—James Brenner, bathoniensis var. alba and others. But none of these seems to reach that degree of merit attained by "the grandest of our Mossies," which was Farrer's unqualified opinion of S. Wallacei.

The least of the tribe of Helianthemum, H. serpyllifolium of the lists, was the first to flower, its neat, little pads of green being studded with golden buttons early in May. But the white-flowered H. umbellatum was only a few days later, and to the credit of this excellent shrub must be added the fact that it survived last winter in places where many of the hybrids were lost. Some delightful possibilities in colour-blending are suggested by one or two accidental groupings which have occurred by using the blue, or lavender, dwarf Rhododendrons with such yellow-flowering shrubs as the small Berberis Darwinii and B. stenophylla hybrids, or such rock garden Brooms as Cytisus Beanii, C. decumbens, Genista pilosa, G. glabrescens and others. It may be that conditions which will suit these little Brooms are not always what one would select for the Rhododendrons. But in this part of the country, at any rate, each race allows one to exercise so much latitude as regards soil and situation that they grow within hand-shake of one another with admirable results. These little Brooms are all so good that one hesitates to indulge in comparisons. But, all things considered, C. Beanii is a shrublet which has no rivals among any of its habit and stature. The earlier, C. Ardoinii, the seed-parent of the last-mentioned, also stands alone as a lowly rock garden Broom of the highest quality, but it seems to need a hotter, drier spot than any of the others named.

In open parts of the woodland some forms of Cytisus hirsutus have been first-rate since early April, the long, whippy wands wreathed with yellow flowers often stained with brown on the standard petal. Rhododendron Williamsianum has again been so injured in foliage and buds by quite light spring frosts that one begins to despair of ever regarding this attractive species as a good garden shrub. Forrest's form of R. racemosum, with bright rose flowers and a semi-prostrate habit, on the other hand, promises to be all that is desirable, and in passing, I would put in a word of praise for that old species, R. punctatum. There are scores of newer introductions which I would willingly discard in favour of this delightful shrub. But it is seldom seen these days, and even its vastly inferior offspring of the R. Wilsonii class are better known than it is. Almost as much might be written of R. Vaseyi, whose leafless branches are covered with lovely, clear pink blossoms. R. ledifolium, quite hardy here, even in such winters as the last, is incomparable in its own way, but a pale pink form, which I first saw in the magnificent Bodnant collection, is also a shrub of matchless beauty, and (I may add) of mysterious origin. *A. T. Johnson, Ro Wen, Conway, North Wales.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

In a recent note (April 13) on the effect of the past winter on vegetation, I included Olearia semidentata among shrubs that had escaped unhurt. At the time of writing, large plants of this choice species showed no trace of injury, their grey-green foliage remaining quite fresh. Since then, however, many branches in shrubs up to eight feet high have wilted and died back, the result, apparently, of the bark splitting. The bushes are not dead, and will recover from disfigurement. Olearia insignis has come through all right, and so has Berberidopsis corallina; but Feijoa Sellowiana has suffered severely, and many plants of Clianthus puniceus in this neighbourhood have been killed outright, including the fine specimen at Logan, which for many years past has sprawled over the roof of a garden shed, making a magnificent display when in flower.

Having made this amend for the error in my former note, may I express a doubt about the warning conveyed in an editorial paragraph on p. 319 to the effect that "it is only in the warmest parts of the country that Rhododendron campylocarpum can be grown with any real prospect of longevity." The climate of Edinburgh can scarcely be accounted as genial, yet there can be few, if any, larger specimens of this beautiful species in Britain than that which stands unprotected on a hill in the Botanic Gardens near the Regius Keeper's house, and is covered year after year with a profusion of its sulphur blossoms.

One more comment: In the article on "the Aftermath of Winter," on the same page 319, Cistus ladaniferus is mentioned as having withstood the cold unharmed. This is remarkable, if correct, for the true Gum Cistus is one of the least hardy species. C. cyprius, a much hardier hybrid between C. ladaniferus and C. laurifolius, often passes for C. ladaniferus; indeed, it was figured in the *Botanical Magazine*, t. 112, under that title. I cannot but suspect that this is the plant in question.

Bulbs sent to me by a generous friend under the name of Fritillaria tristis are about to flower in the open border; but I have searched all authorities at hand without finding any of the genus under that name. Will any kind reader put me on the track of it? Our native F. Meleagris deserves to be more frequently naturalised than is the custom. Both the dark-coloured and the white forms appear as beautiful drifts in the grass, requiring only to be planted in a suitable place, where they will increase liberally from self-sown seeds. I am not sure whether Fritillaries are rabbit-proof. Most of the Lily Order are distasteful to rabbits, which I have never known to molest Scilla, Funkia, Convallaria, Colchicum, Ornithogalum, Ruscus, Erythronium, Asphodelus or Allium, although they devour Grape Hyacinths and Tulips, and sometimes nibble the young shoots of Lilies.

None of the Fritillarias, methinks, equals F. pyrenaica in graceful form of blossom, which entitles that species to a place in the choicest collection of border plants. Let any amateur who has a swampy corner at his disposal plant therein Lysichitum camtschatcense, and forget all about it until next April, when he will receive an agreeable shock from the great golden spathes which will be shot forth, each enclosing a golden spadix. These, as they fade, will be followed by huge, fleshy leaves, and in the next spring by a colony of seedlings, which should be thinned out and the surplus carefully grown in boxes to increase the stock of a very desirable plant. In his *Bulb Book*, Mr. Weathers expresse a doubt whether Lysichitum would thrive in the open except "in the most congenial parts of the kingdom." That doubt may be dispelled by the fact that this Aroid grows heartily in Mr. F. R. S. Balfour's garden at Dawick, in Peebleshire, a cold district six hundred feet above the sea. Moreover, it has flowered as freely as ever here after a winter which has wrought so much mischief in most places.

In the admirable *Annual* of the Rhododendron Association, recently published, it is noted that Rhododendron aemulorum (which we are now bidden to speak of as R. mullotum) has not yet flowered in this country. A small plant of this species, having been planted in the wood when too young, was injured by frost. It was brought in and put in a frame to recover two years ago, and in March this year bore a single truss of intense scarlet flowers reminding one of R. fulgens. It will evidently prove a species of much merit. *Herbert Maxwell, Monreith.*

SNOWDROPS.

WHILE watching the behaviour of Snowdrop seeds, one or two points seem to have been made clear. These may be worth recording.

Mr. A. T. Johnson, writing from Ro Wen, North Wales (*Gard. Chron.*, March 30, 1929), states: "The Snowdrops in the woodland . . . are spreading abundantly by means of seeds in a ground covering of Ivy, about eight inches thick." The Ro Wen conditions appear to be very similar to mine here, where I first noticed seedlings on an Ivy-covered bank. Having lifted a few very small Snowdrop bulbs from this bank and found that they were undoubtedly seedlings, I decided to experiment with some seeds that had been sent to me in 1926 by various growers interested in the subject, both in England and Scotland. These, with others gathered here in 1926, were kept dry until July 21, 1927, and were then sown in lines, side by side with seeds gathered in May and June, 1927. In the spring of 1928 the results were very disappointing. From the 1926 seeds, seeds received from Cumberland produced one plant, and those from Ayrshire, two plants. None of the other 1926 seeds germinated in 1928. From seeds gathered here in May, 1927, one plant appeared, and from seeds gathered here a month later, two plants. Whether these plants were from seeds sown in July, 1927, or from stray seeds in the soil, I cannot state, and judged by 1929 results these six plants may possibly be ignored.

On examination of the lines during the spring and summer of 1928 the round, white seeds could be easily seen in the soil, lying in apparently the same condition as when sown. The ground was protected with wire-netting to secure the soil from disturbance by birds or otherwise. The result this spring has been very interesting. In only one line out of fourteen is there an entire failure. Why this should be, I cannot tell. The seeds which had failed were those of one of the 1926 lots gathered here. In all of the other thirteen lines there are seedlings—in some cases few—in others many.

In the two lines sown with seeds gathered here in 1927, which produced in 1928 two plants and one plant, respectively, there are this season some hundreds of seedlings.

On examining the soil in the various lines, ungerminated seeds are to be seen, apparently unchanged. Some of these have been microscopically examined for me at Edinburgh Royal Botanic Garden, and I am told that they contain good embryos and that there does not appear to be any adequate reason why they should not germinate. It is possible that these seeds may be what are termed "hard" seeds, and they are being watched to see whether they will germinate in another season.

Examining the soil where seeds were sown in 1928, immediately after being gathered, I find that the seeds are still lying there ungerminated. The young plants may be looked for next spring.

Looking over my correspondence, I find that several keen gardeners have written me concerning their failure to germinate Snowdrop seeds. I hope they may be induced to try again, and with patience wait two seasons for the results, when, possibly, they may be able to throw further light on the subject. *P. Murray Thomson, Downshill, Hereford.*

HIPPEASTRUM PROCERUM.

THIS is the giant of the genus, and was introduced by the grandfather of the present M. Binot, about 1863, in which year it was described by Duchartre.

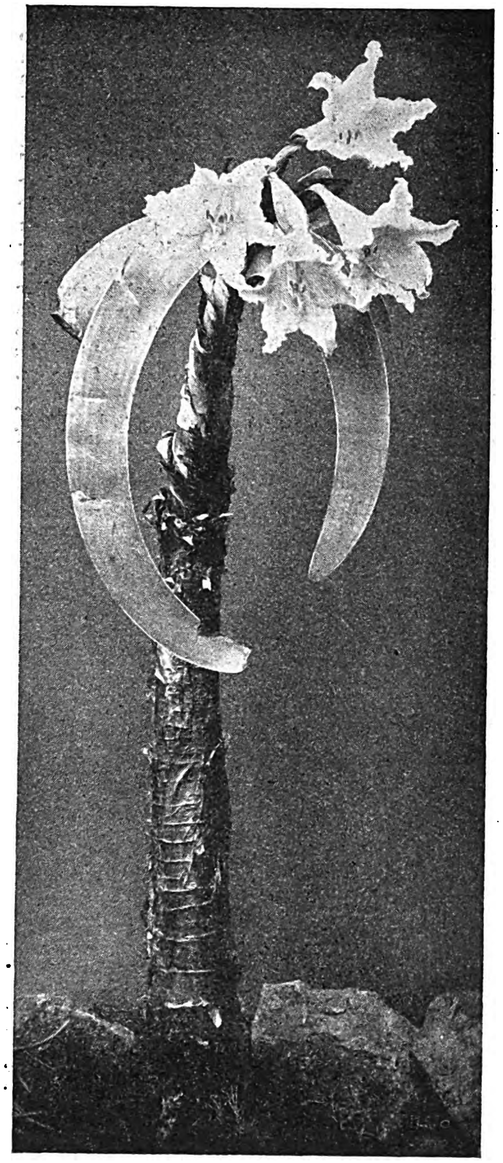

FIG. 188.—HIPPEASTRUM PROCERUM.

Some years ago I made a journey to Brazil for the express purpose of seeing this plant (Fig. 188) in its natural habitat, which is restricted to certain cliffs in the Organ Mountains. Although this was not an economic way of obtaining knowledge of how plants grow, I shall never regret this journey, for it took me through scenes of unrivalled beauty. My friend, the late P. M. Binot, who accompanied me on the expeditions in the mountains, and who possessed a unique knowledge of the flora of that part of Brazil, made my stay in these mountains days of *fiesta.* I collected twenty-seven bulbs, some of them five feet high, which flourished for several years in my garden, and were a source of great delight to many, especially to the late Mr. William Watson, who pressed me to write a monograph on this species. At the time, proposals were made by others for a more extended book on the Amaryllideae, so the monograph was not prepared, and ultimately both projects were abandoned. Growing on ledges, often but a foot wide, on the face of the cliffs, and with little foot-hold but the rock, heavy storms often fling hundreds of the great bulbs down the precipices. But they obtain some support from a species of rambling and trailing Philodendron which intertwines itself among the bulbs and their roots, and forms a kind of rope to hold them in their places. Hippeastrum procerum cannot be confused with any other member of the genus. Its bulb, foliage, and seeds are idiosyncratic, and the colour of its flowers is also distinct. In these respects it hangs on the very edges of the genus—like an appanage which cannot well be placed either in or out of the genus.

From the genetic point of view it should be granted generic rank of its own, for no one has succeeded in crossing it either way with any other species or garden form.* For a number of years, during which it bloomed regularly in my garden, I used its pollen on the large number of species and garden Hippeastrums which I then cultivated, and also attempted reverse crosses on every occasion. But never did fruit form. Not wishing to exhaust the vigour of my bulbs of H. procerum by raising self-pollenated fruits, I only twice self-pollenated in order to examine the fruit and seed. On both occasions fertile seeds were produced and seedlings raised. Hence, it is clear that the failure to raise any hybrids or crosses was not due to improper cultural or climatic conditions, or to any inherent infertility.

Moreover, H. procerum is not the only Hippeastrum which clings to the rock walls of the Organ Mountains, for I also collected H. corriensis,† and H. organense growing with it; and H. aulicum, H. calyptratum and H. Kromeri grow at a lower level. H. reticulatum is found on the low ground. Yet there is no sign of any natural hybrid growing near H. procerum, or of any other species in any way related to it, or filling the gap between it and the rest of the genus Hippeastrum. But it is a fact that the distinctive Rhododendron-like, rosy markings on the outside of the flowers can also be traced, obscurely, on H. corriensis, and also on H. Kromeri. But colour imitation or similarity is no real guide to genetic affinity.

Among the Hippeastrums of this district which are epiphytal, I noticed H. organense and H. Kromeri on tree stumps above marshy ground. It is probable that other kinds may become epiphytic under such special conditions as exist in this district.

NOTES ON THE TERRAIN, CLIMATE AND VEGETATION, ETC., OF THE ORGAN MOUNTAINS.

The first Portuguese navigators thought that the Bay of Rio was the estuary of a river, hence the name "The River of January." After passing a mile or two of rich, littoral land, one reaches the mountains, which are clothed with secondary forest, above which great pillars of bare rock rise to about 4,000 feet or more. If there are still left small patches of primeval forest in this range it is only here and there in inaccessible places. When one reaches the rock above the forest lands, one looks down over a maze of countless valleys running in the wildest confusion in almost every direction. In the bottoms are farms and cultivated lands surrounded by a belt of forest on the steep mountain-sides and crowned by vertical pillars of bare rock, the lower lands running away in the distance down to the glittering waters of the bay. The intricate nature of the terrain paralyses the eye. One feels that one would have to remain in the same place for an hour before the eye could have travelled but once over the many details of the panorama. From an ecstatic condition one is dragged back by a warning that there will be a thunderstorm about four o'clock. However, somewhat similar scenes recur from practically every prominence. But the traveller regrets that he was not so constructed that he could divide himself into two parts, one of which could just look, and the other part hunt for plants.

Among these outstanding parallel pillars of rock there are five that can be seen from a great distance away over the bay; two being higher than the other three. Just before sunrise, when the bay and the lowlands are swathed in a faint mist, the sun suddenly strikes these five highest pillars of rock. By the Jesuit Fathers of those early days the scene was likened to a vast auditorium of worshippers over whom the hand of God was lifted in benediction. May no alleged civilisation ever desecrate this shrine!

---

*Mr. James O'Brien, V.M.H., secured a single seed on H. procerum fertilised with H. reticulatum, and raised a seedling, but lost it in the second year of growth.

† Col. Fig. in *A Selection of Hexandrian Plants*, by Mrs. E. Bury. No. 9. This is the H. Reginae of some Brazilian writers. It is allied to H. organense.

The character of the rock upon which H procerum grows somewhat resembles a soft, porous granite. It is stated that true granite outcrops in places, but what I saw was all secondary rock, much of which had been metamorphosed, and belonged to the classification of *estrato cristalino* of Spanish geology. It has just sufficient roughness for roots to cling well even to plain surfaces of it, and would always give up some moisture at all seasons of the year.

The summer climate at the 3,000 feet level is very pleasant and equable, the day maxima being about 80°, and the night minima about 58°. In winter both are about 15° less, and ground frosts take place for an hour or two at sunrise, but are not serious, and do not descend below about the 2,500 feet level. On the summits of the mountains air frosts are stated to take place occasionally, but plants such as H. procerum, standing close against huge rock walls, would be secured, by the radiation of warmth from the rock, against anything short of a sharp wind-frost.

The winter season is dry, and long rainstorms are unusual in summer, but, although summer forenoons are typically brilliant, thunderstorms take place about every other evening. These break on the mountains round about 4 p.m., but often do not spread to the lowlands, and only last about two hours. Occasionally there is a great deluge, in which as much rain falls in three days as we get in six months. The air in summer is nearly saturated.

As to the plant life on these mountains. The trees are a special study which I would not attempt. But I gave a list, with notes, of eighty-eight species of plants and Ferns which I collected when on my visit. These will be found in *Journal* R.H.S., Vol. XXVIII, Parts 3 and 4.

As access cannot be obtained through the tangled growths on the mountain sides without cutting a path through the undergrowth, and as this is a slow process liable to take up the entire day, the native seeks to save time and labour by approaching the mountain on its steepest side and cutting the pathway up the steepest incline he can find. It would be base flattery to suggest that his scheme assists the explorer in reaching the summit of his ambitions, for the way is arduous and precipitous beyond measure. Moreover, the Indian native makes his passage high enough and wide enough for himself, but not for any fully-grown person. As a result, one has to crouch down, hands on knees, the whole time, and walk sideways as well. The foundation upon which one is supported, although it is invisible, is formed of rough boulders of rock with huge crevices and holes between them. On the top of this is a mattress, some feet in thickness, composed of various aerial roots, vines and trailing plants, the whole of which mattress sinks under foot in a few seconds, so that the art of walking cannot be exercised, but one must jump or run so as not to sink in. The ascent must therefore be made mostly by crawling in monkey fashion, and by clinging on and pulling oneself up by boughs and tree stems. And the descent must be made at a run with as few rolls-over as may be found convenient.

The passages through the Bamboo thickets are nearly in darkness and one longs for a breath of air in the stifling atmosphere.

I would note that, after passing through this forest belt, it was more than an hour before I could hold my hand-camera steadily enough to take a snap-shot.

The methods and objects of cutting pathways are interesting. There are few venomous snakes likely to be met with, but the anaconda is common, and grows to a great size. A chance meeting with a sleeping anaconda is likely to end disastrously for the wayfarer, for although not venomous, it has terrible teeth, and can swallow a wild pig. But it will never attack a man if it has time to glide away.

The various large rodents, wild pigs, etc., can only find their way through these tangled mountain sides by following a path that has recently been cut, and these become impassable in a couple of years. Hence, the anaconda curls himself up and lies in wait for his prey on one of these recently-cut passages. But if a new path is cut the very day the traveller is about to traverse it, he is pretty sure not to come across one. The native will not trust to this, but makes the welkin ring with his yells all the time he is clearing the way for you. No wonder that any chance sleeping anaconda wakes and departs in terror. As a result of these yells, we never caught sight of a snake of any kind. Evidently the native of these parts knows his snake, and, when he kills one, he does not waste it, but eats it so soon as possible. Europeans who have tasted roast anaconda steak tell me that the meat, although rather too firm, is succulent, and resembles a big eel in flavour. In the interior of Brazil, a full-grown anaconda will supply food for a whole tribe of *bravos*, but in the Organ mountains there is not that great scarcity of food which one sometimes experiences in Matto Grosso.

In the forest belt, Sanchezia nobilis was common, both the plain and variegated-leaved forms, several Alstromerias, five or six species of Bamboo, and several Philodendrons.

But the most beautiful individual belonged to fauna—a small batrachian, perhaps an inch or more in length, brilliant orange all over, and shining like a jewel. Its peculiarity lies in a kind of helmet or shield covering the head. After several failures, I succeeded in getting live specimens of this frog home to the British Museum of Natural History. There were imperative physical reasons why I should have noticed batrachians rather than the hosts of epiphytic Bromeliads and butterflies which inhabit this forest zone—for I could never, while climbing, afford for one moment to take my eyes off the ground.

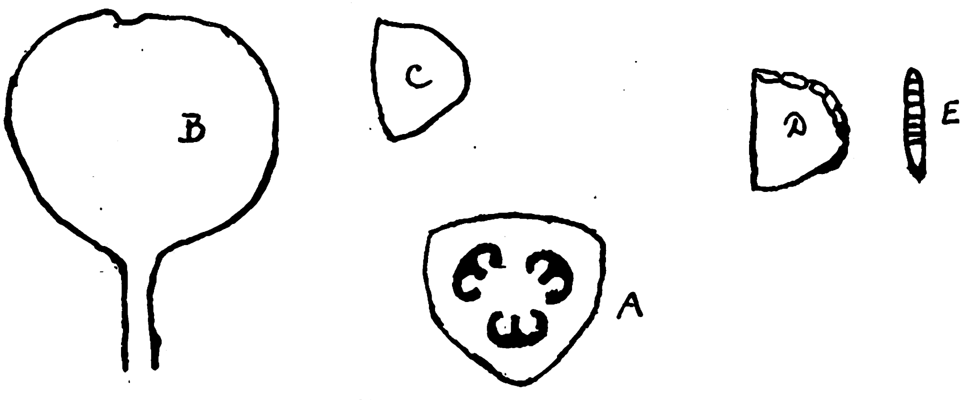

FIG. 189.—HIPPEASTRUM PROCERUM.
Fruit, Ovule and Seeds.

H. procerum, Duchartre.

Fig., in colours, in *Flore des Serres*, Vol. XX, t. 2077 and t. 2078; *Bot. Mag.*, t. 5,883; and also in *The Garden*, Vol. 45, p. 350; and in *Illus. Hort.*, Vol. XI, p. 408.

The first figure is very true, but all the figures I have seen portray the bulb in an erect posture which is not the pose which this plant affects in its natural habitat.

Bulb.—From two to five feet long, rooting on rock, and taking a stance varying from nearly horizontal to one of about 45° above the horizontal; evergreen; somewhat flexuose and ascending towards the apex; about three-and-a-half inches in diameter at base.

Leaves.—A dozen, distichous, falcate, depending vertically, slightly shorter than the bulb, two inches to two-and-three-eighths inches wide, strap-shaped, glaucous, dull emerald-green, with transparent, whitish to pink edges. Narrower-leaved forms are on record.

Scape.—Central, exceeding the bulb by about six inches, much compressed, bearing an umbel of about four* flowers opening in succession.

Valves.—Persistent during flowering, stiffly erect, six inches or less in height by one-and-a-half inch wide.

Pedicels.—Shorter than the valves, almost triangular in section.

Ovaries.— Small. Tube, very short.

Flowers.—All pointing in same direction,† scentless, mauve to intense bluish-mauve, with a white base. General coloration is like that of Griffinia hyacinthina (which is a common plant lower down the mountains). The segments are most deeply coloured towards their apices. The middle zone is lighter in colour, and is profusely spotted with small, reddish-purple spots, and the inner segments are, in this zone, curiously veined towards their edges with short, irregular, mauve markings. Exteriorly, the segments are copiously spotted and flushed with whitish and pink marks towards their bases, and keeled with green at their apices. Span, four-and-a-half to five inches. Limb, six inches.

Segments.—The three inner one-and-a-quarter inch wide, the three outer more than one inch, overlapping the inner. In some forms the segments are not so wide.

Stamens.—Contiguous, much shorter than the limb.

Pollen.—Light yellow.

Style. — Exceeding the stamens but shorter than the limb.

Stigma.—Tri-capitate, ciliate.

Fruit.—Dehiscing in five months, and containing forty-four or forty-five jet black, D-shaped seeds. These are much thicker than in other Hippeastrums, not at all winged, but very acutely angled, with all edges raised. The edges of seeds touching the outer envelope of the fruit are strangely marked (see Fig. 189), although the envelope itself is smooth. They show about six transverse marks or bars on their double edges.

Gestative Period.—About two-and-a-half times as long as is the case in other Hippeastrums.

In the fruits raised at Isleworth a good proportion of the seeds were fertile, and the seedlings grew well for two years, but slowly. Their appearance was true to type.

This plant will withstand temperatures down to the freezing point for a short time, but, being evergreen, it should not have its growth brought to a complete standstill by cold. It will grow in temperatures between 40° and 55°, and will expand its flowers fully at day temperatures of about 60°. In its natural habitat the temperatures at this period vary between 55° and 75°. The flowering period in the Organ mountains is January and February, corresponding to our July and August. March is the close of the flowering period (our September). Bulbs which I brought to Isleworth flowered with me in March the year after introduction, but three years later they flowered in August.

The cultivation of Hippeastrum procerum

---

* I know nothing of the twelve-flowered scapes described by some authors, but the presence of six subsidiary bracts indicate the possibility of a six-flowered umbel, as shown in the Fig. in *Flore des Serres*.

† Away from the wall of rock and retaining this character under cultivation. Is this a case of "fixed heliotrophy"?

is full of difficulty. To succeed, one should construct a house in which an almost saturated atmosphere could be maintained, combined with a briskly moving air. This could only be obtained by the use of air-fans. Winter temperatures ranging from 40° to 55° should be arranged for, and, for summer, some 12° higher. No shading should be allowed excepting about midsummer, when it would sometimes be found necessary to prevent the sun from rushing the temperature above 80°.

The big bulbs must be supported at an angle of about 45° with the horizontal until they have obtained a firm root-hold on rock. With me, they did fairly well in nine-inch drain pipes filled with rock, charcoal and chippings of stone, covered with a little Oak-leaf and bits of live moss (not Sphagnum). Owing to the exposure of the roots, a constant war must be waged on wood-lice and such enemies. Any bulb planted in earth will certainly die in a year or so.

Description of Sketches of Fruit, Ovules and Seeds (Fig. 189).

A.—Section through middle of ovaries at time of flowering, showing position of ovules on placenta (slightly enlarged sketch).

B.—Life-size outline of ripe fruit containing forty-four to forty-five seeds.

C.—Life-size outline of seed.

D.—Life-size outline of seed showing bar-like marks on double edge of seed where contiguous to inner side of fruit-husk.

E.—Life-size end-elevation of seed, showing thickness of seed and same bar-like markings. *A. Worsley, Isleworth.*

ALPINE GARDEN.

INCARVILLEA GRANDIFLORA VAR. BREVIPES.

Hailing from the upper Lichiang valley, on the eastern slopes of the Lichiang range, north-west Yunnan, Incarvillea grandiflora (Franch) var. brevipes (Sprague) is well worth a position in a sunny situation in the rock garden, where its woody root-stock can penetrate far down into the cool soils beneath; for in its natural surroundings it is found on gritty exposed positions and on the open mountain meadows.

I. g. var. brevipes (Fig. 190) was described and given its varietal name by Mr. Sprague so long ago as 1909, in the *Kew Bulletin* of that year (p. 263). It was described from dried material collected by Mr. G. Forrest a few years earlier, and also from plants grown and exhibited by Messrs. Bees, Ltd., at the Temple Flower Show, under the name of I. Bonvalotii. The varietal name refers to the short pedicels, as compared with the true I. grandiflora.

I. g. brevipes is a luxuriant grower, the flower stems being seven to twenty inches in height, with two to seven leaves to the plant, dark green and pinnate, the segments of which are serrate and of varying lengths, with an acute apex; the terminal segments are suborbicular and much larger than the lateral segments, very often two inches in diameter, but this character is very variable. The petioles are from one to three inches in length and brownish-green in colour. The large, Gloxinia-like flowers of rich crimson colour are borne at the apex of single stems, in two or threes. The calyx is from half-an-inch to an inch in length and campanulate in shape, with five acute lobes. The corolla tubes are two to three inches in length, by two to three inches from tip to tip of the large, orbicular segments. The base and inside of the tube have a yellow flush, with white streaks, the latter persisting further on the inside lower half of the flower. The stamens, four in number, hardly reach the mouth of the tube, but the pistil is longer, and may be just discerned when looking into the throat of the corolla.

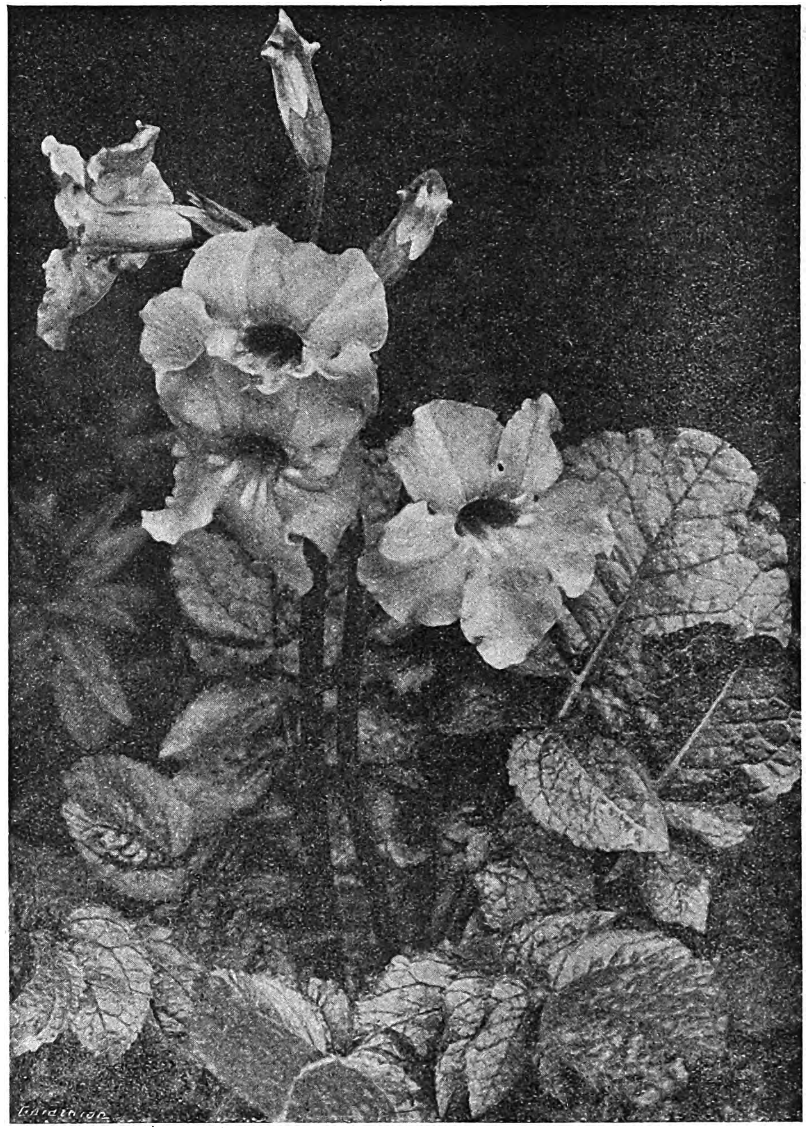

FIG. 190.—INCARVILLEA GRANDIFLORA VAR. BREVIPES.

SEDUM KIRILOWII VAR. RUBRUM.

Sedum Kirilowii var. rubrum (Fig. 187) is a charming though somewhat unusual type of plant, closely resembling in habit our native S. roseum. It is found in the mountains of central Asia. The plants at Kew appear to grow from eight to fifteen inches in height, throwing up their glabrous, green stems, stiffly erect, from woody rhizomes. The stems are a quarter-of-an-inch to half-an-inch in diameter, thickly clothed with bright green, linear leaves, nearly two inches in length by rather more than a quarter-of-an-inch in width, standing out horizontally from the stem, but with a slight upward tilt at their apex; they are slightly serrated.

The flower heads are of a brick-red colour, two to three inches across and arranged in a corymbose cyme. The individual flowers are roughly three-sixteenths-of-an-inch in diameter, with the petals and sepals about an eighth-of-an-inch long, from the base of which arise the stamens, these being about double the length of the petals and crowned with small golden anthers. The species appears to be dioecious, for in the female flowers the stigmas and styles are of the same colour as the petals, and they are not nearly so charming as the male flowers.

The plants like a fairly open, sunny position, though sheltered, where they can fix their roots firmly into well-drained, rich soil. *A. Edwards, Kew.*

LINUM FLAVUM.

One has some hesitation in stating that Linum flavum is the best of the few yellow Flaxes in cultivation, seeing that we have L. arboreum and a few others in our gardens, but it may well claim to be among those in the first rank, both for beauty and comparative hardiness. I state "comparative hardiness," as it is not absolutely reliable, even in less trying seasons than this has been. Happily, however, it sows itself with considerable freedom under favourable conditions, and young plants from self-sown seeds frequently survive when others fail. A few seeds may also be saved to maintain the stock. Given, however, a dry, sandy soil and a sunny position, the fear of loss will be greatly minimised.

Linum flavum is more herbaceous than shrubby and generally produces fresh growths from the base each spring. It grows from nine to twelve inches in height, keeping to its dwarfest stature in very dry soil, and produces pleasing, glossy leaves and a long succession of large, golden-yellow flowers from early summer onwards. The late Reginald Farrer stated that it often comes a deeper orange from seeds, but, although I have raised many seedlings, I have never found any variation in the shade of yellow. L. flavum, which ranges in its native habitats from Russia to Germany, has been in cultivation since 1793, when it was introduced from Austria. Farrer records numerous varieties. *S. Arnott.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXI.—THE ADVANCE CONTINUED.

COOLIES had been promised for May 7, to take us up the valley to a place called Cha Che, just above the last Mishmi village on the other side of the river. We wanted to make this our base. We could see this village, and also Cha Che, from near our camp, or rather, we could see just where they were among the bulges of the valley, being only a few miles away. However, we were told that as the fast rising Delei had swept away the bridge up stream, it would be necessary to fix a rope bridge before we could cross, so that it would take two days to reach Cha Che, the best part of one day being spent crossing the river.

May 6 was another bright day, so I decided to retrace my steps up the mountain to the ridge where the 'Barbatum' Rhododendron and Viburnum Wardii were flowering so finely, taking with me a guide, as well as a camera, in case I missed the track again. I reached the ridge in under three hours, got my photographs, and was back in camp again by 4 o'clock. On the ridge I noticed shoots of the 'Irroratum' Rhododendron, badly frosted and killed; I also collected fresh material of the flowering species to replace those so badly damaged the previous day. In the temperate forest Quercus lamellosa was the only naked tree, having just finished shedding its leaves, and not yet acquired new ones; even Magnolia rostrata was now fully clothed.

On the 7th, only about three dozen coolies of the fifty required turned up, so we sent them off with loads and ourselves waited until the next day. The balance came on the 8th, and off we went.

The climb along the cliff face in the gorge was as bad as it had looked, but luckily no rain fell to make the rocks and ladders slippery. A pretty Abelia with golden-yellow flowers grew in the thickets here, and I also collected a curious Arisaema with a twisted spathe. In the afternoon we reached the river, a wide torrent, roaring over boulders as big as cottages, and found the working party putting the finishing touches to the twisted Bamboo rope (Fig. 191); this was fixed in position the same evening while we camped on the bank. The river banks were lined with trees and shrubs, among which were Birch and Oak, Cornus Nuttallii in flower, and a curious tree of the family Celastraceae—a species of Kurrimia, perhaps. It bore both flowers and ripe fruits, and my attention was drawn to it by the piercing fragrance of the small, yellow flowers; the seeds are glutinous to the touch, and retain this stickiness even after they are dry—or rather, they never do seem to dry properly.

May 9 was fine and very hot. Although the coolies started getting the loads across at 6.30, it was two o'clock before we were all on the other side. The rope was three-stranded, each strand made of eight slivers of Bamboo, the thickness of fine string, carefully plaited; large rings, also made of Bamboo, were threaded on the rope, and the boxes, suspended from these rings, were hauled across by means of a light line made of creepers. So were we! The Mishmis, however, travelled across under their own power with great speed; they looked more like monkeys than ever.

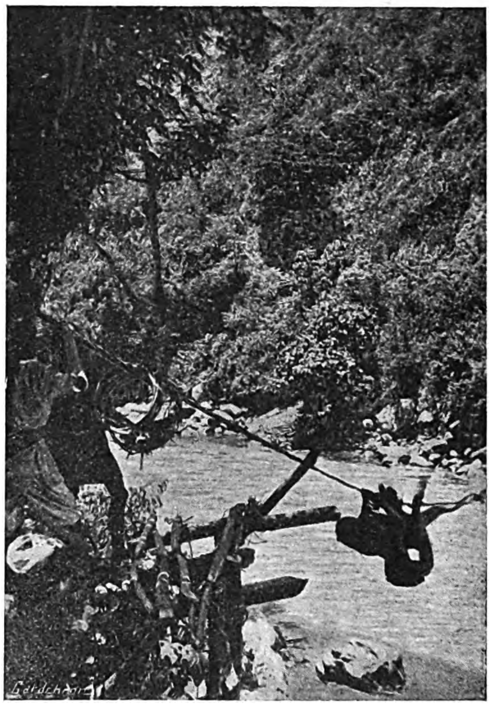

FIG. 191.—CROSSING THE DELEI RIVER BY A BAMBOO ROPE BRIDGE.

A short ascent brought us to the last village in the Delei valley—three huts perched on a very steep face at a height of about 5,000 feet! A deep ravine divided Tajabum, as it was called, from Cha Che, whither we now proceeded. A very insecure natural log bridge, strengthened by a hand-rail and one or two struts, crossed the torrent, which dashed right over the bridge. From here a precipitous ascent brought us to Cha Che, a short and narrow undulating ledge of rock on the face of the cliff in the very eye of the midday sun. Close by, a small stream slid over the cliff; and on this ledge the Mishmis had constructed a *basha* like a doll's house.

It was quite impossible to light a fire in the *basha* without setting it alight, while in the other half, where our boxes were stacked in a close cube, it was impossible to open anything without first dragging it outside, and if it happened to be underneath, impossible to drag it outside without first dragging out a good many other things. Finally, there was no room to dry any paper, either in the sun (when there was any), or over a fire; the lightest breeze would send over the cliff any paper laid on the ground. As for our tents, they were half pitched on the undulating ledge, with sagging canvas and tangled ropes, and being unable to put up our beds we had perforce to sleep on the uneven ground. Such a situation was all very well for a week; as a permanent base camp it was, of course, inadequate. We demanded to be taken back to Tajabum, proposing to make our base there, but the old man of the village refused to have us there, saying there was no ground—nor was there. The Tajabum contingent, in fact, were rather hostile, and, indeed, all the Mishmis were beginning to murmur against us.

We now made enquiries about the path to the pass, and tried to persuade the coolies to go on next day to a better camping ground; but we soon discovered that this was as far as they would take us, now or in the future. They were adamant on that point, and convinced us that they meant what they said. There was a path—one or two young men had been up the valley to its head—but few people went, coolies could not carry loads there, and at this time of year it was impossible, because there were several unbridged streams to cross, which, rising behind them would cut them off from their homes. So there we were, two or more marches from the pass, in an impossible position, our plans collapsing like a house of cards before our eyes. Nothing would move the Mishmis, and, in fact, the interpreter was rather worse than useless, because whenever he was told to tell the Mishmi coolies anything he thought they would not like, he sulked; he translated the longest speech uttered by the *gam* curtly in half-a-dozen words, and it was clear that not only had he no influence over these people but that he sided with them.

Buttercup and I discussed the position until midnight, but the only possible solution that we could see was to return to the village and try to reach the alps in another direction. But first, to get the Mishmis to take us back. Next morning we argued, harangued, threatened, and persuaded for hours. The coolies sat on, waiting for their pay, but I said that unless they took us back they would get no pay. Still they refused. And from that day there began the long drawn out, scarcely veiled warfare between ourselves and the independent Mishmis, which could have but one end.

At last I could stand this stalemate no longer; either the coolies must take up our loads and walk, or, if *we* could not go back to the village, neither should they; I would cut the rope bridge. Taking a native knife, I started for the bridge, which I reached in an hour. It was a blazing hot day, and sitting there in the open, with one eye on the path above. I was slowly roasted. After a long vigil, two coolies came into view; neither of them carried a load, and I promptly cut the rope bridge, then started up the path back to camp. I had not got far when Buttercup appeared, and told me that the coolies had been prevailed upon to take us back—they were coming along; the two coolies I had seen were not ours at all. Here was a pretty kettle of fish! Unconscious of anything wrong, the coolies were coming along, having procured a little food from Tajabum, and now their communications were cut, and we were all marooned on the wrong side of the river! The position was undeniably bad, but I was not very repentant; in an impasse, I must always *do* something, even if, as here, it happens to be the wrong thing.

When the coolies reached the bridge and saw what had happened there was a fine shindy! My interpreter, too, had collapsed from an overdose of Opium and looked as though he was going to die. There was nothing for it but to camp by the river for the night.

Next day the *gam* gathered his clansmen together, told us what he thought of us, and said they were all going down stream to another rope bridge, and when they were all across they would cut it behind them, and we could stew in our own juice. The final act was rather comic, because the Mishmis, in a rage, tore down their shelters, kicked out their fires, and hurled the timber into the river; in fact, they behaved just like naughty children tempestuously breaking their toys because they could not have their own way. Then the whole party streamed away. I kept a stiff upper lip, but did not feel at ease. The equanimity of Buttercup at this crisis was invaluable, and Luso, our Kashmiri cook, took it all calmly.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, and 27; and May 18, 1929.

The next three days were terribly hot and stuffy, and we did literally stew. But the *gam* was no fool; his people had not yet been paid, a bridge was required here, and anyhow to leave us indefinitely might end in reprisals. Within an hour one of his lieutenants returned to act as liaison officer and come to terms. This was soon done, and off went this warrior to make a new bridge, or rather, to repair the old one; more Bamboos had to be cut, and a length of new rope woven into the old, which, of course, was dragging down river on the other side, being still attached to the supports on the far bank.

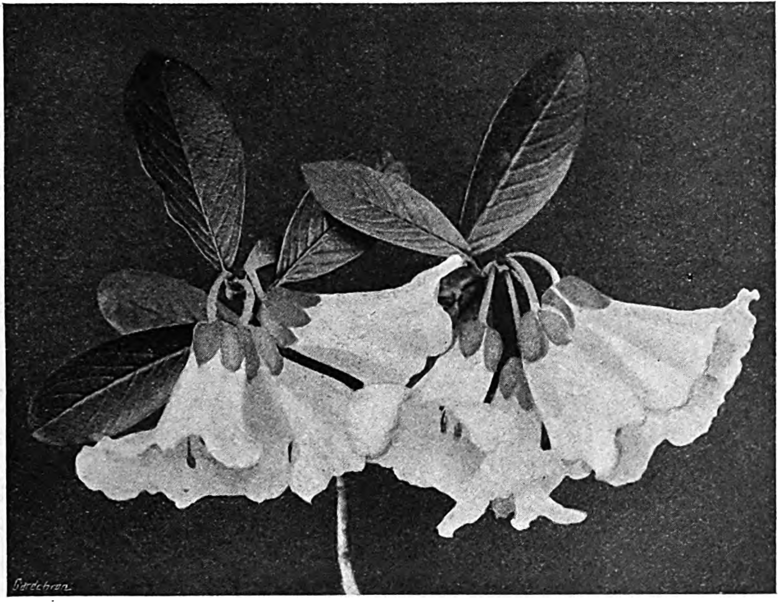

FIG. 192.—RHODODENDRON MEGACALYX.

Sure enough, on the evening of the second day, our man appeared on the far bank with the necessary raw materials. A second man then appeared, and repairs were put in hand; and by the third day, help having been summoned on our side, the rope was fixed in position and some of our boxes slung across. *F. Kingdon Ward.*

TREES AND SHRUBS.

VIBURNUM CARLESII.

Mr. Alfred Unger, Heidelberg, writes:—"I read in *The Gardeners' Chronicle* of May 4, (p. 338)—in connection with the announcement of the death of Mr. William Richard Carles—some remarks about Viburnum Carlesii, which was named after him. The gentleman who sent the note appears not to be sufficiently acquainted with the plant in question, and I am anxious to put this matter right, for the introduction of the first living plants into Europe was due to me. About thirty years ago, I received the first plant of this Viburnum from Korea through a friend. After the first flowers appeared, I sent a few leaves and flowers to Kew, and received a reply to the effect that they had it in their herbarium, and that it was named Viburnum Carlesii. Thereupon I sent the first living plant to Kew, and a few years later sold my stock of about ten plants to Messrs. Lemoine, of Nancy, France, who propagated the species and distributed it throughout Europe. I wrote the first article about this Viburnum, and it appeared in *Möllers Deutsche Gärtner Zeitung* in 1904 or 1905, with a photograph of a vase of flowers."

[The record in the *Botanical Magazine*, t. 8,114, states that "In 1801 Messrs. L. Boehmer and Co., nurserymen, at Yokohama, Japan, sent a cultivated specimen to Kew to be named, with the information that it had been raised from seeds obtained from Corea in 1885. A living plant was received from the same firm in 1902, and this flowered in the Arboretum in May, 1906. *Le Jardin* for August, 1902, p. 229, reproduces a photograph of a cluster of flowering branches received from a Mr. T. Eckhardt, also of Yokohama. . . . The same photograph was reproduced in *The Gardeners' Chronicle*, October 11, 1892." The *Botanical Magazine* dates are wrong. There was no issue of *The Gardeners' Chronicle* of October 11, 1892, and the illustration referred to appeared on p. 261 of our issue for October 11, 1902; the photograph reproduced, and the notes, were contributed by "A. Unger, proprietor of the firm of Mr. L. Boehmer of Yokohama." Mr. Bean in *Trees and Shrubs Hardy in the British Isles*, states: "Native of Corea; introduced from that country to Japan, in 1885, by Mr. Unger of the firm of L. Boehmer and Co., Yokohama. A single plant was sent to Kew by the same firm in 1902, which represented its first introduction to Europe."—Eds.]

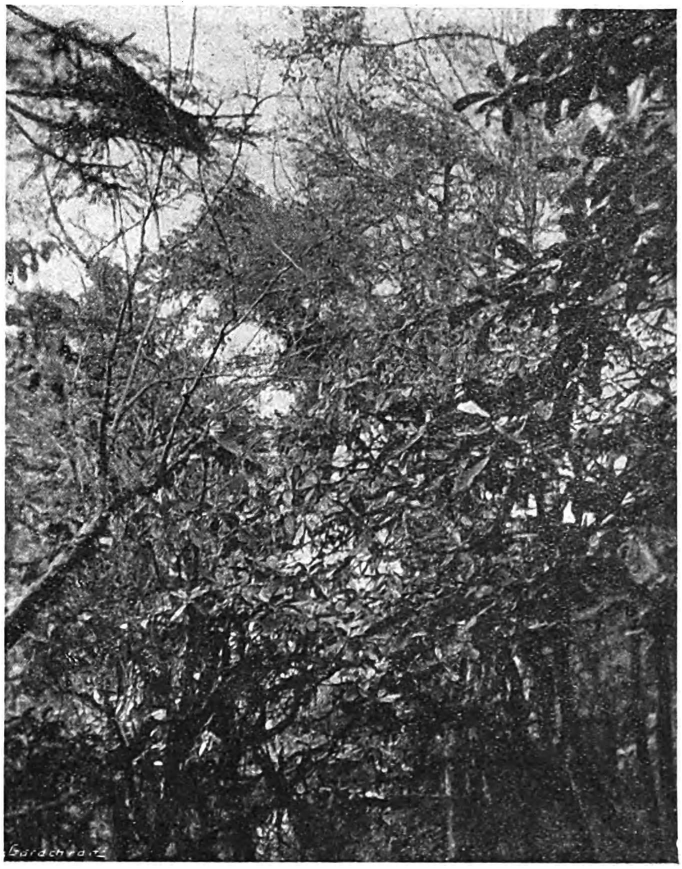

FIG. 193.—A TANGLE OF RHODODENDRON FOREST, 8,000 FT. ALT.

LINDERA BENZOIN.

Known here under the name of Benzoin aestivale, Mr. W. J. Bean deals with this hardy American shrub under the title of Lindera Benzoin, and remarks that "it makes a neat bush of no particular merit or distinction." It is very plentiful in this locality, occurring especially in moist situations, and during the month of April it is rendered attractive by the numerous small, greenish-yellow flowers which are borne on the previous year's wood, producing much the same effect as do the flowers of Cornus Mas, and showing to particularly good effect against a background of dark evergreens. In the fall, the leaves turn to a clear, bright yellow hue, and the branches are studded with the small, oval, scarlet fruits, producing a most pleasing effect.

The name of Spice Bush is commonly applied to this shrub because of the pungent, spicy odour which is apparent when the wood and leaves are bruised; it is also known as the Benjamin Bush.

Lindera Benzoin will attain a height of from six to fifteen feet, and bears oblong-obovate leaves from three to five inches in length, with ciliate margins. They are bright green above and paler beneath. The bark of the Spice Bush is aromatic, stimulant, tonic and astringent, while the fruits are also used medicinally.

Propagation is effected by means of layers, greenwood cuttings or new seeds; it should be noted that the seeds soon lose their vitality. *T. H. Everett, Pleasantville, New York, U.S.A.*

ROYAL HORTICULTURAL SOCIETY.

EXHIBITION AT CHELSEA.

May 22, 23 and 24.

PRECEDED by gloriously fine weather and favoured by similarly happy climatic conditions on the opening day, the Chelsea Show of 1929 will be remembered for many years to come as a brilliant success in spite of the long, severe and dreary winter that lingered even into "the merrie month of May." The great extent, great beauty and great interest of the exhibition held in the grounds of the Royal Hospital, Chelsea, surpassed expectations, and provided ample evidence of the unrivalled skill and undaunted perseverance of British cultivators. The odds were all against a great show, but the verdict of many who have had wide experience of Temple shows and Chelsea shows, was that this spring exhibition of the Royal Horticultural Society "was better than ever."

There was no official opening or royal visitation on the opening day, but Princess Mary, accompanied by Viscount Lascelles, paid a lengthy visit to the exhibition during the afternoon of May 21, while judging was in progress. Fifty gentlemen, from all parts of the country, accepted invitations to act as judges, and these accomplished their difficult tasks between the hours of 3 p.m. and 6 p.m., and were afterwards entertained to dinner in the Ranelagh Café by the President, Mr. Gerald Loder, and the Council.

Rock gardens were once again a great attraction, while the formal—and informal—gardens were arranged in larger number and greater variety and interest than usual. The exhibits of trees and shrubs out-of-doors added to the spring-time beauty of the permanent trees and shrubs; it was Lilac time, and almost Hawthorn time, at Chelsea.

Under canvas, the exhibits as a whole displayed a glorious riot of colour such as has never been excelled at a Chelsea Show. Messrs. **Sutton and Sons** had a wonderful exhibit of greenhouse plants and annual flowers; indeed, they surpassed themselves; alas! the exhibit did not lend itself to the eye of the camera—it needed a very wide space around it, to enable its charms to be appreciated to the full. An exhibit of unusual interest was the one arranged by **Lady Aberconway** and the Hon. **H. D. McLaren**, Bodnant; this contained nearly one hundred particularly rare and choice plants. Carnations, Sweet Peas, Azaleas, Rhododendrons, tropical foliage plants, Calceolarias, Begonias, Delphiniums, Paeonies, Irises, alpine plants in wondrous beauty and variety, Hydrangeas (we heard them called "high Geraniums"), and Lilies were a few of the subjects that secured general admiration. Orchids and Roses had each a tent to themselves; the former were, as usual, a great attraction, and made a beautiful display of grace and colour, while the Roses scented the air with their fragrance. Astounding vegetables, tempting Strawberries and Apples in wonderfully fine condition, all added to the interest of the show. The educational features and the horticultural sundries section we shall deal with in due course.

One exhibit deserves special mention. It was grimly romantic and altogether extraordinary. This was the display of Californian plants brought over and arranged by Mrs. A. **Sherman Hoyt**, of Pasadena, whose portrait we have much pleasure in publishing (on p. 372). The Cacti, the Redwood scene, and the Death Valley (Fig. 195), combined to make an exhibit generally described as "wonderful" and "extraordinary." Mrs. **Sherman Hoyt** brought over this exhibit and arranged it at her own expense; she has presented it to the Royal Botanic Gardens, Kew, and, in addition, she has donated a thousand dollars to the Royal Horticultural Society. Mrs. **Hoyt** is a generous, enthusiastic and enterprising lady, and deserves all the congratulations she received.

Finally, a few words of appreciation are due to the fine work of the members of the Council of the R.H.S., to Mr. F. R. Durham, and Mr. A. Simmonds, the Secretary and Assistant Secretary, respectively, and the whole of the staff, who laboured long and so successfully.

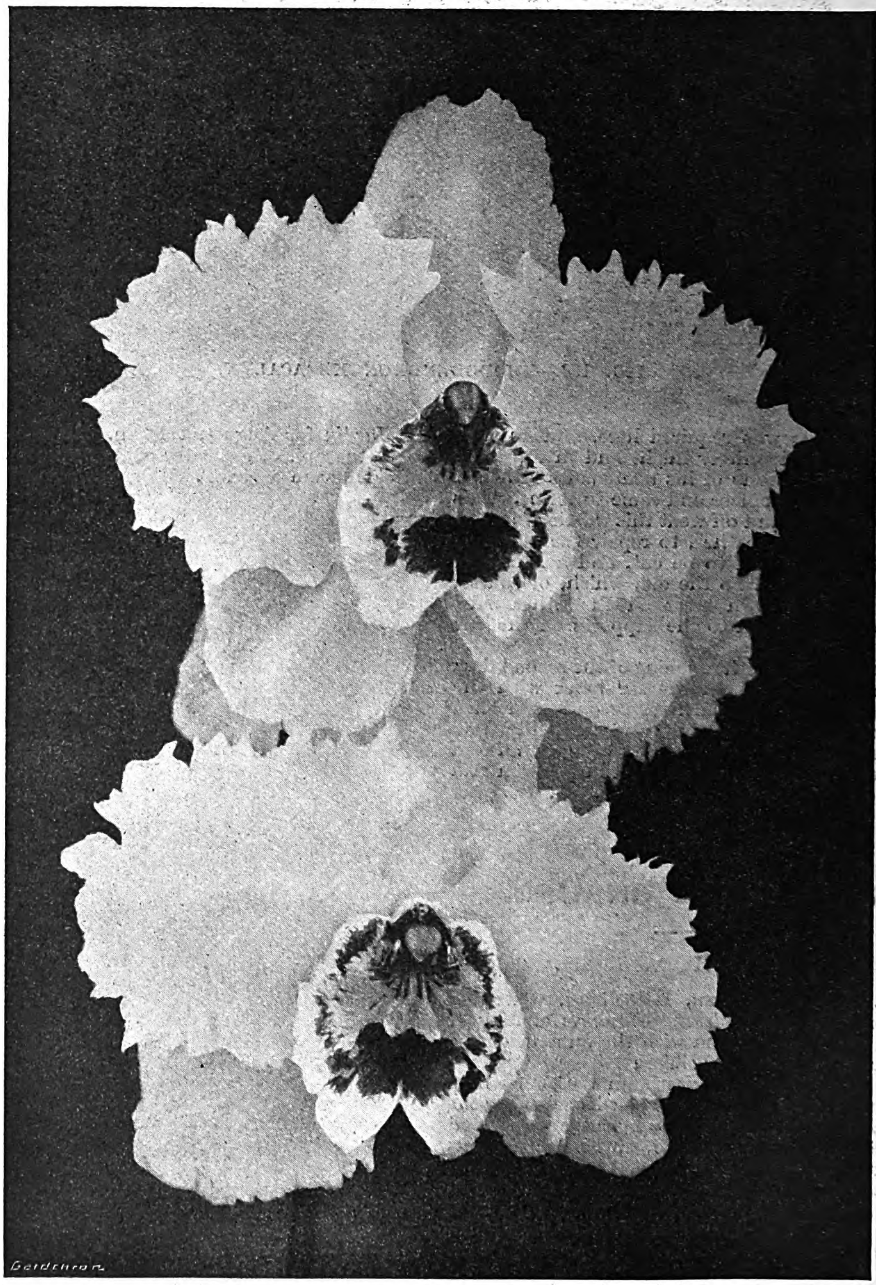

FIG. 194.—CHELSEA SHOW: ODONTOGLOSSUM CRISPUM VAR. PROTISTUM

Flowers pure white. A superb variety exhibited by Messrs. Charlesworth & Co.

The exhibitors, too, and their staffs, merit thanks for accomplishing what, a few weeks ago, appeared to be the impossible.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. Lionel de Rothschild, Mr. J. C. Cowan, Mr. E. R. Ashton, Mr. T. Armstrong, Mr. H. G. Alexander, Mr. Robert Paterson, Mr. Richard G. Thwaites, Mr. Frederick J. Hanbury, Mr. Fred K. Sander, Colonel Stephenson Clarke, Mr. S. W. Flory, Prince Shimadzu, Mr. A. A. McBean, Mr. Charles H. Curtis, Mr. J. E. Shill and Mr. Stuart H. Low.

First Class Certificates.

Odontioda Prince Olaf (*parentage unknown*).—A very beautiful hybrid with shapely flowers of considerable substance. The sepals and petals are deep red, with rose tinting at the edges and tips, while the flat lip is rose-coloured, red at the base, and with a handsome golden disk. Shown by Messrs. Sanders.

Miltonia T. B. Armstrong (*M. vexillaria var. Leopoldii* × *M. William Pitt*).—An attractive hybrid, with deep rose, red-tinted sepals and petals, a blackish mask, and with a wide white zone between it and the wide rosy frontal portion. Shown by Messrs. Armstrong and Brown.

Odontioda Laura, Exbury var. (*Oda. Brewii* × *Oda. Coronation*).—This handsome hybrid betrays its O. Brewii parentage in the deep colouring and substance of its shapely flowers. The colour is deep crimson-scarlet, with a golden disk. Shown by Lionel de Rothschild, Esq. (gr. Mr. B. Hills, Exbury, Southampton).

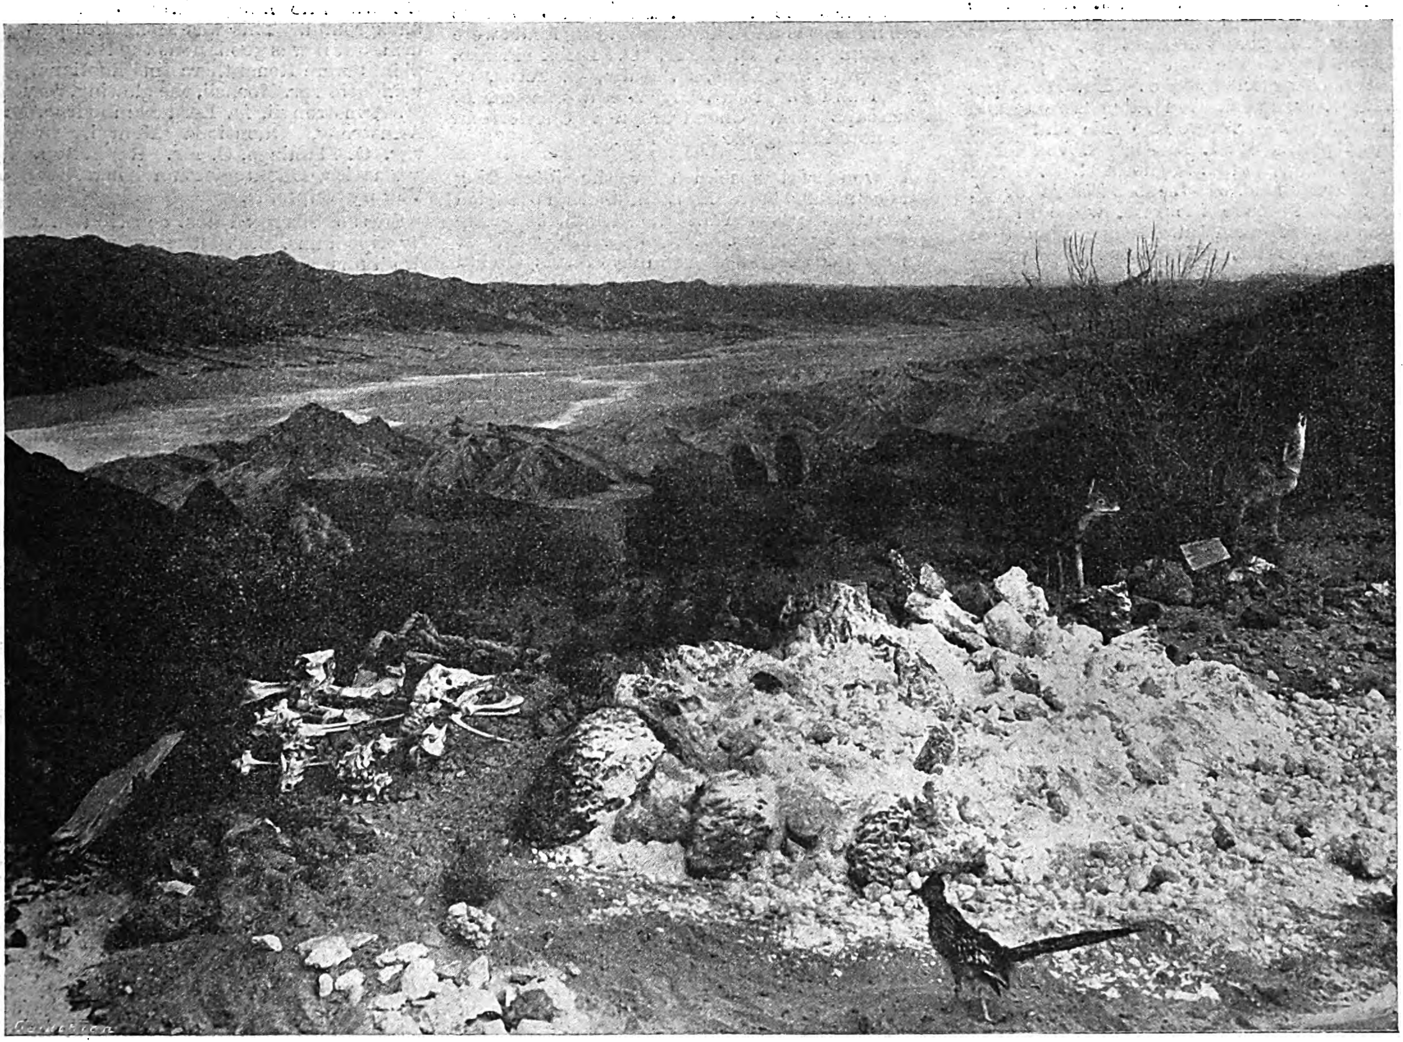

FIG. 195.—CHELSEA SHOW: DEATH VALLEY, CALIFORNIA, EXHIBITED BY MRS. A. SHERMAN HOYT.

Phalaenopsis Gilles Gratiot (*P. Aphrodite* × *P. Rimestadiana*).—A splendid pure white Phalaenopsis of fine proportions and substance; the lower halves of the wings of the lip are yellow, and there are a few purple dots below the yellow disk. It may well be described as a glorified P. Rimestadiana. Shown by Messrs. Sanders.

Cattleya Prince Shimadzu var. King George (*C. Tityus* × *C. Hardyana*).—A fine form of a fine hybrid. The wide petals are of a lovely mauve shade, with frilled edges, and the sepals are of similar colour. The big, frilled lip is intense crimson-purple over the frontal portion, and gold at the base and throat. Shown by Messrs. Black and Flory.

Awards of Merit.

Lissochilus speciosus.—An old Orchid in cultivation, but one seldom seen. It is a terrestrial species from Natal, and produces tall—three feet to seven feet—spikes of yellow and greenish-yellow flowers, each about two inches wide. Two plants were shown, one—the better—by W. R. Lysaght, Esq. (gr. Mr. T. Briscoe), Castleford, Chepstow; and the other by W. van de Weyer, Esq. (gr. Mr. A. George), Clyffe, Dorchester.

Dendrobium Prince Arthur var. Colossus (*D. Regium* × *D. Euryalus rubens, Gatton Park var.*).—A large-flowered form with soft, bluish-mauve sepals and petals and a white base and throat to the lip. Shown by Sir Jeremiah Colman, Bt. (gr. Mr. B. F. Perfect), Gatton Park, Surrey.

Odontioda Zarina var. Brilliant (*Oda. Chanticler* × *Odm. crispo-Harryanum*).—In this hybrid the flowers are unusually rounded and broad. The colour is a bright shade of salmon, with pink edges to the sepals and petals and a salmon-pink tip to the golden-disked lip. Shown by Messrs. Cowan and Co.

Cypripedium bellatulum var. King George. This finely-formed flower has very large purplish spots and it is a very attractive form. Shown by Dr. F. T. Paul, Caldy, Cheshire.

Brasso-Laelio-Cattleya Gordon Highlander var. Majestic (*L.-C. Aphrodite* × *B.-C. Maronae*).—A very large and magnificent flower of this variety was shown. The sepals and petals are pale pink, the sepals being faintly mauve-tinted. The splendid lip is finely frilled, mauve, shaded with purple, and with a wide, soft, golden throat and brown lines at the base. Shown by Messrs. Stuart Low and Co.

Laelio-Cattleya Berenice (*L.-C. Lustre* × *L.-C. Madame Brasseur Hye*).—A large and finely proportioned Laelio-Cattleya with broad, mauve petals and narrower mauve sepals. The wide, rounded, frilled lip is rich royal purple, with gold veins in the throat. Shown by Messrs H. G. Alexander, Ltd.

Brasso-Cattleya Orange Glory (*L.-C. Elinor* × *B.-C. heatonense*).—A glowing and arrestingly beautiful hybrid of clear, light and bright orange-yellow colouring, the tint being slightly deeper on the petals and in the throat of the finely-frilled lip than elsewhere. Shown by Messrs. H. G. Alexander, Ltd.

Odontioda Leeana var. Vivid (*Cochlioda Noetzliana* × *Odm. crispo-Harryanum*).—A gloriously-coloured form and well-named, as its finely-proportioned flowers are of a bright rich grenadier-scarlet hue, with a golden disk and a gold edge to the front of the lip. Shown by Messrs. J. and A. McBean.

Cattleya Susan var. alba (*C. Suzanne Hye de Crom* × *C. Cowaniae var. alba*).—A lovely Orchid with wide, white sepals and petals, and a white, frilled lip that is heavily shaded with soft lemon-yellow. Shown by Messrs. J. and A. McBean.

Brasso-Cattleya The Globe var. Mrs. Simon Gay (*B.-C. Cliftonii* × *C. Trianae*).—The sepals and petals of this large-flowered variety are palest mauve-pink, while the big lip has a fringe and base of similar dainty colour, with a wide, light purple area, and a pale yellow throat. Shown by Frank Mercer Esq. (gr. Mr. F. Bank) Clovelly, Steyning, Sussex.

Preliminary Commendation.

Miltonia Armstrongii (*M. Miss Louisa Fowler* × *M. William Pitt*).—In this hybrid the flower is deep crimson-tinted cerise, with a brown, white-edged mask. Shown by Messrs. Armstrong and Brown.

Cultural Commendation.

To E. R. Ashton, Esq. (gr. Mr. Kent), Broadlands, Tunbridge Wells, for Dendrobium atroviolaceum, with ten spikes; to J. B. Joel, Esq. (gr. Mr. C. J. May), Childwickbury, St. Albans, for Cypripedium. Rothschildianum, Northaw House var., with eight spikes of flowers.

Groups.

Sir Jeremah Colman, Bt. (gr. Mr. J. M. Richards), Gatton Park, Reigate, exhibited a very fine group of well-grown plants. Conspicuous in the background and centre were tall examples of Dendrobium Gatton Sunray, very fine, and D. Dalhousieanum luteum, while in the foreground were examples of D. Prince Arthur. Particularly fine were the Lycastes, for which the Gatton Park collection is famous; these included L. Skinneri varieties Mrs. Hamilton Smith, Rainbow, delicatissima, Fulshawense and Hellemense. Miltonas were also fine and there were large plants of M. Lyoth, M. vexillaria, M. Princess Mary, and M. Memoria G. D. Owen. Splendid specimens of Lælio-Cattleya J. F. Birkbeck stood above the rest, while in the foreground were such interesting plants as Cœlogyne pandurata, Polystachya paniculata, the wonderful Bulbophyllum Bennendyckii, B. macrobulbon, Dendrobium Victoria Reginae, Cattleya citrina, Vanda cristata and Cypripedium Godefroyæ leucochilum, Gatton Park var. Altogether a grand exhibit.

J. J. Joicey, Esq. (gr. Mr. J. Mackay), The Hill, Witley, set up a very pretty exhibit of bright and interesting Orchids. Anguloa Clowesii was the central feature and Cymbidium Lowianum formed the background, with Cattleya Mossiæ and the fine old Laelia purpurata Miltonias were well represented by M. vexillaria, M. v. var. Lyoth, M. Princess Margaret and M. Papillon, while bright colour was provided by Odontioda Bradshawiana, O. Chanticler, O. Charlesworthii and O. Grenadier. Interesting and uncommon orchids included Gongora, sp., Aerides Fieldingii Maxillaria sanguinea, Bulbophyllum Lobbii and the very old Selenipedium Dominianum.

Only ten plants were exhibited by E. R. Ashton, Esq. (gr. Mr. C. V. Kent), Broadlands, Camden Park, Tunbridge Wells, but every one was a specimen and particularly fine for so late in the season, they were D. atroviolaceum (2) one carrying ten spikes, D. Thwaitesæ, D. nobile var. Cooksonii, D. Owenianum, D. nobile var. virginata, D. Sir F. E. Moore (2) and D. Ainsworthii, Hazelbourne var.; a finely grown set.

Messrs. H. G. Alexander, Ltd., contributed a corner group in which one of the features was a colony of the brilliant orange coloured Laelio-Cattleya Orange Gem, with one plant of L-C. Syrinx var. Dulce. Larger-flowered Laelio-Cattleyas were represented by fine examples of L.-C. Gretal var. magnifica with nine flowers; the splendid L.-C. Berenice; L.-C. Clarion var. magnifica, L.-C. Cassandra, L.-C. Gladiator and L.-C. Meuse, Westonbirt var. Cattleya Mossiae was well shown, together with C. M. var. Wagneri, C. M. var. Reineckiana, C. Iris and C. Muriel var. alba and C. Skinneri. A few Cymbidiums filled the angle of the group, swinging their spikes over Cypripedium Holdeni, Westonbirt var. A good example of Vanda suavis occupied a prominent position and two other fine Orchids were Brasso-Cattleya Orange Glory and the rich orange-red Sophro-Laelio-Cattleya Falcon, Westonbirt var.

The bold display made by Messrs. Sanders contained two "hanging groups" of the lovely Phalaenopsis Rimestadiana, carrying an aggregate of about thirty spikes of pure white flowers. Cymbidiums were a prominent feature and these were represented by large specimens of C. Ceres, C. Erica Sander in variety and C. Mary Sander, all carrying an abundance of sturdy spikes. Oncidium Marshallianum was associated with the Cymbidiums in effective fashion. Miltonias were shown well and included M. Venus and M. vexillaria in great variety. Brasso-Cattleya Shillianum and fine forms of Cattleya Mossiae made a brave show.

A few special Orchids were Brasso-Cattleya Salta, Phalaenopsis Grand Condé, P. Gilles Gratiot—two hybrids, Dendrobium acuminatum, Odontioda Prince Olaf, Miltonia Fletcheriana, Cymbidium Devonianum, C. Huttonii and the lovely Burrageara Windsor. A fine display but a trifle crowded.

The striking arrangement made by Messrs. Mansell and Hatcher attracted attention and admiration. In the centre, and raised, was a delightful grouping of Miltonias in great variety, including hybrids and varieties of M. vexillaria. Below this feature was a colony of Cypripedium bellatulum with a few examples of C. Maudiae and C. Curtisii var. Sanderae. Very fine were the spikes of Odontioda Flamingo O. rosefieldensis, O. keighleyensis, O. Edith Hodgson, O. Bradshawiana, O. Vuylstekae and O. Charlesworthii. These were grouped with Odontoglossums on either side of the Miltonias. The Odontoglossums were numerous and a few outstanding kinds were O. triumphans, O. Lena, O. Black Prince, O. crispum xanthotes, O. Italia, O. Cetus, O. Mirum and O. Horus. Lycaste aromatica, L. breviscapa and Chondrorhynca Chestertonii were noted along the front line.

A wonderful specimen of the interesting and beautiful Dendrobium acuminatum occupied the central position in the delightful group arranged by Messrs. J. and A. McBean. It was by far the finest example of this Orchid we have ever seen. It had eighteen long, drooping spikes carrying a total of three-hundred-and-sixty rose-red flowers and buds. If the Cooksbridge firm had shown nothing else this would have been an outstanding example of their cultural skill. The group was finely arranged, and contained a fine collection of Cymbidiums, Miltonias, Odontoglossums, Odontiodas, Miltonias and Lycastes, the whole making a charming effect. A few outstanding plants were Cattleya Susan var. alba, Miltonia Kennie var. Princess Elizabeth, Brasso-Cattleya The Globe var. Mrs. S. Gay, Brasso-Laelio-Cattleya Queen of the Belgians, Oncidium McBeanianum, Coelogyne pandurata, Dendrobium Victoria Reginae, Odontioda Grenadier, Miltonia Bleuana var. virginalis, O. Leeana var. Vivid, O. Madeline and Epiphronitis Veitchii.

Dr. F. T. Paul, Caldy, Cheshire, submitted Cypripedium bellatulum in variety, as well as C. concolor, C. Psyche and C. Chapmanii; there were sixteen plants, all in fine condition.

The largest display in the Orchid tent was made by Messrs. Charlesworth and Co., who had a group across the end of the tent, and extended into two short right-wings at right-angles. Odontoglossums were the outstanding feature of this fine exhibit, and in the centre of the group several dozen spikes of lovely forms of O. crispum were surrounded by hybrids of brilliant colour, and made a lovely display. The finest of the crispum forms was O. c. var. protistum (Fig. 194), of lovely form and fine size. The coloured, hybrid Odontoglossums, included O. Asmode, O. Norman, O. Toreador, O. Imperator, O. Nubia, O. Romulus, O. Matador, O. Eudora var. Aesculus—very fine, and O. Jamesianus var. Radium. Vanda suavis was finely represented, as were Coelogyne pandurata, Vuylstekeara Aspasia, and Miltonia William Pitt; Odontiodas and Cattleyas were also shown, but did not figure largely in this splendid exhibit.

Messrs. Black and Flory arranged their plants quite clear of the background of Palms and Ferns, producing a kind of stereoscopic effect. A fine feature of the display was the brilliance of the Cattleyas, and among these the finest were C. Prince Shimadzu var. King George, with a glorious gold and purple lip; C. H. B. Turner, C. Hardyana in variety, C. Mossiae in variety, C. Irene, C. Sohma, C. Chelsea var. scintillans, C. Canada var. Chelsea, C. Flammea and C. Dr. Lacroze var. Rosalind. Miltonia Kennie var. Rosalind, M. Doris, M. Bleuana, M. Gertrude West and M. Lena were used with advantage, and Cypripediums and Odontoglossums finished the front of the exhibit.

A bright and lightly-arranged display from Messrs. Stuart Low and Co. was much admired. This firm used Cymbidiums, Oncidiums, Bamboos and Palms in the background, while similar Orchids of lowlier stature rose from the Cattleyas and Odontoglossums. Brasso-Cattleyas were notably prominent, and represented by B.-C. André Maron, B.-C. Mirabilis, B.-C. Jupiter, B.-C. Apollo, B.-C. Baroness, B.-C. Empereur de Russie var. Purity, and B.-C. Leemanae. Good Cattleyas were C. Tityus and C. Skinneri, while Laelio-Cattleya Hyeana, L.-C. G. S. Ball—very fine—and L.-C. Canhamiana were not less beautiful. Rarer and interesting subjects were Cyrtopodium Andersonianum, nearly six feet high and with a head of yellow flowers; Epidendrum Parkinsonianum, Bifrenaria Harrisoniae, Zygo-colax Charlesworthii, Coelogyne pandurata and Cypripedium niveum.

Beautifully and lightly arranged were the Orchids exhibited by Messrs. Armstrong and Brown who hung Miltonias on their velvet background. This was a small display for this firm, but it was good, none the less. Prominent plants were Renanthera Imschootiana, Miltonia vexillaria var. Moensii, the glowing, rosy-crimson M. Armstrongii, M. Lord Lambourne, M. T. B. Armstrong, Odontioda Henryi, Orchidhurst var. O. Flamingo, O. Mr. R. Felton, Lycaste aromatica, Odontoglossum King Albert and O. Victory Supreme.

Messrs. Sutton Bros. contributed a group of Cypripediums, Brasso-Cattleyas, Miltonias, Dendrobiums and Cypripediums; the last were arranged along the foreground, and included C. Rossettii, C. Maudiae and C. barbatum; Ada aurantiaca and Dendrobium chrysotoxum also figured in this group.

Messrs. Cowan and Co. made a bold display wherein Brasso-Cattleya Shilliania, Brasso-Laelio-Cattleya Jupiter, L.-C. Aphrodite, L.-C. Hassallii var. alba, Cattleya Waltersiana and C. Mossiae were outstanding features. A very large-flowered form of Oncidium varicosum was associated with Cymbidiums, while Odontoglossums, Odontiodas and Miltonias figured at the ends of the display, and Cypripedium bellatulum, C. Curtisii var. exquisitum and C. beechense var. magnificum figured in the foreground.

Mr. Harry Dixon grouped Cattleyas and Laelio-Cattleyas in the centre of his display, and raised Lycaste aromatica, L. Skinnerii var. Ruby Gem, Cymbidium tigrinum, Cymbidium Devonianum and Dendrobium atroviolaceum above small plants of Odontoglossums, Odontiodas, Miltonias and Cypripediums.

Floral Committee.

Section A.—Mr. Henry B. May (in the chair), Mr. Arthur Turner, Mrs. Ethel M. Wightman, Mr. R. Findlay, Mr. J. T. West, Mr. Donald Allan, Mr. W. B. Gingell, Mr. J. M. Bridgeford, Mr. M. C. Allwood, Mr. D. Ingamells, Mr. R. B. Long, Mr. F. C. Langdon, Mr. J. B. Riding, Mr. William Howe, Mrs. Helen Lindsay Smith, Mr. J. F. McLeod, Mr. D. B. Crane, Mr. H. R. Darlington, Mr. Charles E. Pearson and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. W. J. Bean (in the chair), Mr. W. G. Baker, Mr. G. Reuthe, Mr. George Harrow, Mr. James Comber, Mr. T. W. Taylor, Mr. Eric M. Marsden-Jones, Mr. J. J. Crosfield, Mr. John Millais, Mr. A. Bedford, Mr. L. R. Russell, Mr. R. W. Wallace, Mr. Clarence Elliott, Lady Beatrix Stanley, Mr. G. Yeld, Mr. R. C. Notcutt, Sir William Lawrence, Bt., Mr. W. Irving, Mr. F. G. Preston, Mr. Amos Perry and Mr. N. K. Gould, Secretary.

First Class Certificates.

Magnolia Brozzonii.—A Soulangeana hybrid which has large, white flowers, lightly tinted and veined with rosy purple towards the base of each segment. Shown by Lionel de Rothschild (gr. Mr. A. Bedford), Exbury, Hampshire.

Rhododendron Vanessa.—The reason for the high award to this Rhododendron is not readily apparent. The bush is of spreading, shapely habit and flowers when comparatively young. We understand that it is a R. Souliei hybrid. The trusses are loose and carry medium-sized pink-shaded flowers which have carmine spots at the base. Shown by Lady Aberconway (gr. Mr. F. 3. Puddle), Bodnant, North Wales.

Awards of Merit.

Daphne tangutica.—A desirable Chinese, sub-evergreen, little shrub. It is of sturdy, erect habit and flowers freely. The alternate, lanceolate leaves are dark green. The flowers are white with bright rosy-purple exteriors and buds. Shown by Messrs. Bees, Ltd.

Paeonia Mlokosewitschii.—An uncommon herbaceous species. The foliage is luxuriant. The flowers are of a medium yellow tone and the calyx segments curved inwards. Shown by R. D. Trotter, Esq., Ockley.

Rhododendron Muriel Messel.—A very beautiful variety raised by crossing Loder's White with Loderi. The bright pink buds expand widely and are of lovely pink shades with carmine spots. The trusses are very large and shapely. Shown by Lt.-Col. L. C. R. Messel, O.B.E. (gr. Mr. J. Comber), Nymans, Handcross, Haywards Heath.

Ourisia alpina.—The ovate, serrate leaves make a dark green rosette from which spring the reddish-stemmed inflorescences. The lilac-pink flowers, which are borne in opposite pairs, have relatively long, purple stalks set in leafy bracts. Shown by Captain McEacharn, Galloway House, Wigtwonshire (see Fig. 199).

Primula hybrida var. Sir George Thursby.—A seedling from a cross between P. japonica and P. Lissadell hybrid. It is a vigorous, free-flowering plant, bearing whorls of large, deep rose-pink flowers which have irregular velvety-crimson zones. Shown by Mr. G. H. Dalrymple.

Dodecatheon splendidum var. Brilliant.—An improved variety of distinct garden value. It bears good spikes of bright rosy-purple flowers. Shown by Mr. Amos Perry.

Rhododendron Fortune's Triumph.—A compact, truss of large, pale pink flowers which have bright carmine spottings at the base. Apparently this is rather less tender than others of its type. Shown by G. H. Johnstone, Esq. (gr. Mr. S. Skelton), Treversands, Grampound Road, Cornwall.

Aponogeton leptostachyum var. lilacina.—A pretty little Pond-weed. The leaves are about two inches in length, and the small, forked inflorescences have tiny, rosy-lilac flowers. Shown by Mr. Amos Perry.

Rose Barbara Richards.—A very beautiful, fully double H. T. variety of good form. The large, fragrant flowers have broad, recurving petals of creamy-white colour with a biscuit-yellow flushing in the centre. Shown by Messrs. Alex. Dickson and Sons.

Statice profusa var. superba.—This is a greatly improved variety. It is exceedingly floriferous and the purple bracts are relatively large. Shown by Mr. W. Chandler, Rolvenden.

Begonia Mrs. J. Raeburn Mann.—A splendid, double-flowered, tuberous-rooted variety of glowing pink colour. Shown by Messrs. Blackmore and Langdon.

Rock Gardens.

It was fully evident that rock gardens retain their great popularity with both the exhibitors and the public, for the customary space at the Embankment end of the grounds was fully occupied with the gardens which attracted a large throng of admirers throughout the show.

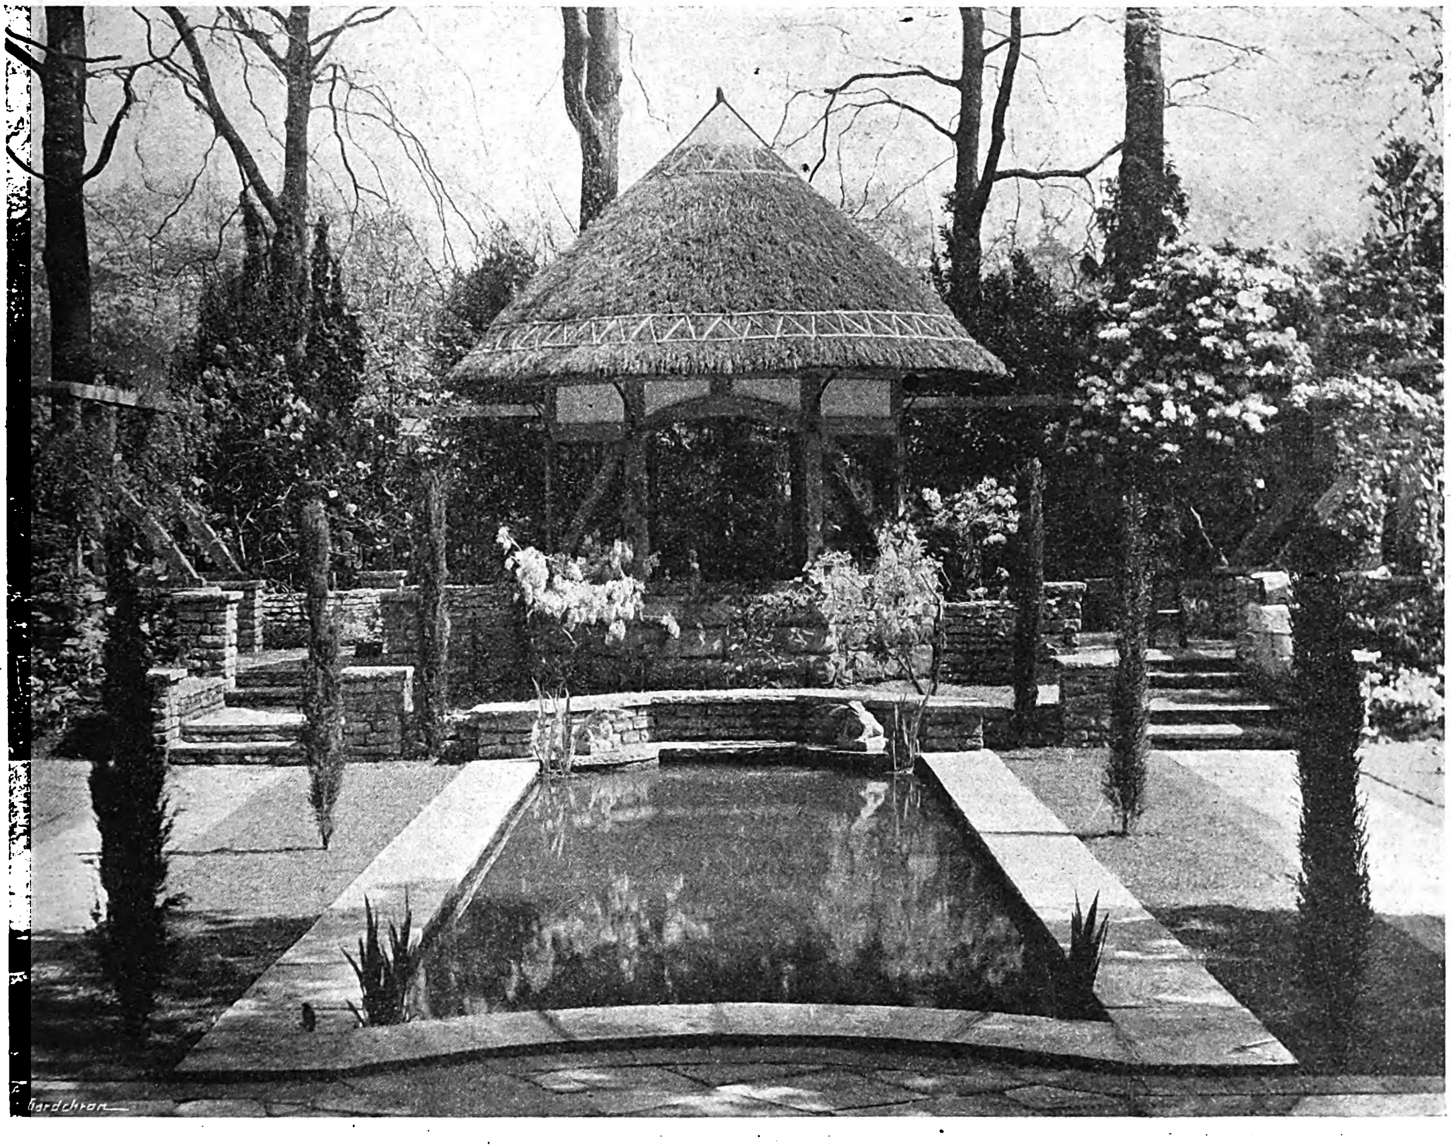

FIG. 196.—CHELSEA SHOW: MESSRS. R. W. WALLACE AND CO.'S FORMAL GARDEN.

No doubt, obedient to the expressed wishes of the Council of the Society, this year's rock gardens displayed a much greater diversity of material and treatment than those of recent years. The result would seem to have attained the object in view, but we feel that it must be conceded that this important feature of the Chelsea Show lost in general effectiveness. Viewed as individual efforts there was a certain gain, but the effect as a whole was not equal to that of recent years.

The rock garden of the Orpington Nurseries Co. was somewhat of the form of a shallow, grassy bay, backed by boulders of weathered stone, clad with mosses and lichens which gave an old-established appearance, while towards the front there was a pool. The principal plants used were dwarf Pines, Brooms and Azaleas, with Lithospermum Heavenly Blue, dwarf Irises and Saxifrages.

A sandstone rock garden with a background of Pines and deciduous shrubs was made by Messrs. W. E. Th. Ingwersen, Ltd. The chief alpines were Phlox compacta, Gentians, Androsaces, Geums and Aubrietias.

A spacious effect was obtained by Messrs. Hodgsons, Ltd., who had ample greensward in front, with weathered boulders and a waterfall at the back. Bright colour was provided by double-flowered Gorse, various Japanese Maples, Alyssum saxatile varieties, dwarf Phloxes and double Trollius.

A sandstone rock garden with a grassy mound in the middle was shown by The Hardy Plant Nursery. At the foot of the mound they had generous breadths of Iris stylosa and also used Japanese Azaleas, Thrifts, Sedums and Saxifrages.

A neat little rock garden was made by Mr. Ernest Dixon at the Avenue end. He planted various Saxifrages, Alyssum saxatile varieties, dwarf Phloxes, Alpine Auriculas and, towards the back, some Japanese Azaleas, Brooms and other shrubs.

A pleasant rock garden was made by Messrs. Tuckers, Ltd., with weathered boulders of moderate size. The disposition of the stones was distinctly good and, in the bright sunshine, the dry stream-bed was quite appropriate, and of natural appearance. In the background they grouped various low Pines, with Brooms and Azaleas. The general planting, though, perhaps, on a lavish scale, was bright and attractive. Prominent among the many plants were Saxifraga pyramidalis and various other Saxifrages, Meconopsis Baileyi, Alyssum saxatile varieties, many dwarf Irises, Geums, Gentians, Cheddar Pinks, Phlox Vivid and blue Aquilegias.

An uncommon design was adopted by Mr. Clarence Elliott in the bold outcropping of his rock garden, and the isolated boulder, surmounted by a mature specimen of Pinus montana over various Stonecrops found many admirers. The background was also treated very successfully, and here were prostrate Junipers, Brooms and Azaleas behind boulders which sheltered ample sweeps of Phlox Vivid, P. Douglasii var. Lilac Queen, P. G. F. Wilson, Viola gracilis var. Grandeur, Iris cristata, Oxalis enneaphylla rosea and various Saxifrages. A nook in the middle of the garden contained several rarer plants, particularly the dwarf Calceolaria Darwinii bearing its relatively large pouches of crimson, gold and white, which attracted the alpine enthusiasts. The general planting was wisely restrained, although sufficient

Perhaps the most imposing rock garden was that of Mr. G. G. Whitelegg, even although it did not contain the very largest boulders in the show. His exhibit was made up of large Cumberland stone piled up towards the back, and tumbling streams, with a pool at the front. Various Conifers were placed effectively in the background and elsewhere, and often these were associated with Brooms, Azaleas and other shrubs. In most instances the boulders were capped with either prostrate Junipers or masses of alpines, such as the dwarf Phloxes, Stonecrops and Saxifrages. In the foreground there were goodly patches of golden Trollius, Phlox Vivid and other sorts, Alyssum saxatile varieties and Daphne Cneorum.

Although it did not seem to have found great favour with the judges, the rock garden of Messrs. Pulham and Son had many admirers among the visitors. Towards the back there were pleasant boulders of Cumberland stone yielding a waterfall of natural appearance which tumbled down to a still pool. The plantings, which were done with knowledge and skill, included Daphne Cneorum, Phlox Vivid, golden Trollius, Saxifrages in variety, Lithospermum Heavenly Blue, several Dodecatheons, Sisyrinchiums, and a brilliant patch of Spanish Broom.

The largest stones in the show were the immense boulders used by Mr. Gavin Jones, who also had a waterfall which fed two pools. In one corner of his exhibit he had an effective planting of dwarf Irises, Gentians, Androsaces, Primulas and Saxifrages, while by the pools he placed Funkias, Primulas and other appropriate plants.

Stove and Greenhouse Plants.

Appropriately enough, the superb exhibit of Messrs. Sutton and Sons (Fig. 197) was placed in the middle of the large tent, where, on a considerable space, they displayed very many splendid plants, all of them grown from seeds. The general scheme of a series of bold mounds of flowers, and winding paths, provided many most delightful vistas. The tent rafters provided a fitting place for the display of an enormous number of plants of the drooping Begonia Lloydii, a plant which was also used to great effect, with a groundwork of moss, in masking the tent pillars. Well within the group there was a large mound of the magnificent Salpiglossis which Messrs. Sutton and Sons grow so well. The other principal mounds were of blue Cinerarias, both of the stellata and large-flowered types, large-flowered Calceolarias of great excellence, and Gloxinias. For many years the Reading firm has shown Streptocarpus of considerable excellence, but never before so finely as on the present occasion, while the tuberous-rooted Begonias were of much more than the usual quality. A surprise item was the pool where Gloriosa Rothschildiana rambled over the sides and hung its gorgeous flowers to be mirrored in the still waters, and the richly golden Richardia Pentlandii gave the appropriate bright colouring.

An extensive collection of tropical plants, set out by Messrs. L. R. Russell, Ltd., was one of the features of the show. Exceedingly well-grown Codiaeums (Crotons) were freely used, and these were mostly as tall, single-stemmed specimens furnished with beautifully coloured leaves from top to bottom. The principal sorts were Prince of Wales, Eugene Draps, Warrenii and Golden King. The many foliage plants also included vigorous, highly-coloured Dracaenas, and Alocasias in considerable variety, while in the foreground there were some exquisite Marantas. The principal flowering plants were Epiphyllum Gartneri, of which there were two splendid batches, Gloriosa superba and Gloriosa Rothschildiana, various Bromeliads, and Clivias.

A very meritorious collection of miscellaneous stove and greenhouse plants was shown by Messrs. John Peed and Sons. In this were well-grown Codiaeums and Dracaenas, and many Caladiums, of which the chief sorts were Mrs. C. Cooper, William Manning, Red Ensign and Triomphe de Comte, which have large, reddish leaves; Mrs. John Laing, Harry Coleman and Mercedes d'Argent, green and white-leaved varieties, and the nearly transparent Rio de Janeiro. Along the front, Messrs. John Peed and Sons placed very excellent plants of Gloxinia, Streptocarpus and Begonias, with Hydrangeas, Dracaenas and Lilium longiflorum var. giganteum in the middle distance.

The exhibit of Messrs. J. Carter and Co. was severely formal in outline, but the beauty of the many plants and their artistic placing successfully prevented any stiffness in effect. An ample centre was edged with a perfect grass border and surrounded with the ideal gravel walk which, in turn, was contained within four grass-bounded sections, and altogether made a garden of charm, grace, dignity and restfulness. In the centre, the tent pole was masked by graceful Bamboos, Palms and Acer negundo variegata, while around this were grouped excellent plants of Salpiglossis, well-furnished with large flowers of delicate texture and exquisite veining.

In the outer sections there were circles of Hippeastrums, Clarkias and Streptocarpus, surrounded by Gloxinias and larger mounds of stellata Cinerarias and Calceolarias of both the large-flowered type and the graceful Clibrani. The necessary relief was given by occasional plants of Cocos plumosus, specimen Codiaeums (Crotons), and raised vases of Sweet Peas.

An enormous collection of splendid Hydrangeas was exhibited by Mr. H. J. Jones. This plant does not lend itself easily to effective grouping, but Mr. Jones contrived, with great success, to make a very fascinating display. The rich pink varieties were represented by Duchess of York, H. B. May, Queen Mary, D. B. Crane, Florence Bolt, a new variety of a charming soft shade of colour, and the deep pink Lord Lambourne. Chief among those of blue shades were Blue Prince and Vicomte de Vitraye. Other varieties of value were Madame de Vries, white with light flushing; David Ingamells, rich pink, with lighter centre, and Neidersachsen, pale blue.

Messrs. Dobbie and Co. made a large bank of their Perfection strain of Calceolaria, which well illustrated its great value. The many plants showed great cultural skill, and bore large-pouched flowers in many beautiful colours

Large masses of Cineraria stellata, hybrid Schizanthuses and double scarlet Clarkia formed the background of the extensive group of Messrs E. Webb and Son. With this background were displayed Salpiglossis, Primula obconica gigantea, Cineraria Matador, Nemesia strumosa varieties, Statice Suworowii and large-flowered Calceolarias.

A neat group of large-flowered Calceolarias was arranged by H. P. Russell, Esq. (gr. Mr. G. Tydeman), The Nine Gables, Bexley Heath.

A collection of double-flowered Begonias of the high quality now expected from them, was displayed by Messrs. Blackmore and Langdon. As is usual, the flowers surpassed the Camellia in size, and were of perfect form and delicate colouring. Chief among those of pink shades were Queen of the Belgians, Mrs. H. Moncrieff, Mrs. T. Crawford, Lady Ann, Mrs. Reginald Caulfield and Mrs. R. R. Anderson. Varieties of orange colouring were fairly numerous, and the most prominent were Irene Tambling, Florence Bigland and Lord Lambourne, while the chief yellows were Mrs. J. Davidson and Mrs. J. L. Rushton. Mrs. F. Bedford, a beautiful creamy-blush, Princess Victoria Louise, pale salmon; Albatross, white; Sir H. Wilson and C. E. Pearson, scarlets, were also of great beauty. Raised above these excellent varieties were some valuable basket Begonias, such as Gladys, red; Bertha, pale salmon; Mollie, blush, and Lena, scarlet.

Many trusses of Zonal Pelargoniums were set up by Mr. W. A. R. Clifton. The chief doubles were Genetrix, Madame A. Roseleur, Captain Hazel and Lave, while prominent among the singles were Mrs. F. J. Searles, Somerset Lad, Willingdon Gem, Drummer Boy and Prince of Wales.

Next to their Carnations, Messrs. Stuart Low and Co. grouped miscellaneous stove and greenhouse plants, including Anthuriums of considerable merit, the fascinating Bottle Brush tree, Metrosideros robusta, Hippeastrums of merit, Gloriosa superba, several very floriferous Mimosas (Acacias) and Magnolias.

Formal and Other Gardens.

An unusual, yet very attractive garden was planned and made by Mr. Ernest Dixon. At the entrance was a wall garden with a sunken centre which provided fascinating circular recesses with stone seats for rest and contemplation. The raised portion was planted pleasantly with seasonable shrubs and border flowers, among which Alyssum saxatile in variety and Cheiranthus Allionii gave breadths of welcome colour.

A square, paved forecourt made by the London Gardens was planted with a dwarf Ageratum and pot-grown Mignonette, while the window boxes contained Hydrangeas.

Mr. James Macdonald made one of his perfect grass gardens with a central pool containing a leaden figure and enclosed by a neat Yew hedge. The lawn grass was of the richest green and innocent of even the most minute weed. Many of the best ornamental grasses added to the garden's attraction, and the four beds of Phleum pratense aurea and the six-feet-high plants of Eulalia japonica testified to the cultural skill of the growers.

An exceedingly bright and attractive garden of St. Brigid Anemones was laid out by Messrs. Reamsbottom. Except for the centre, which was of mixed colours, the beds were filled with distinct varieties. Victory, a glowing scarlet, with a pure white zone, made a great show, while the satiny-mauve Dorothy Plunket was exceedingly effective.

The Japanese garden designed and made by Messrs. W. Wood and Son, struck a new note at Chelsea and attracted a deal of deserved admiration (Fig. 198). An air of agreeable spaciousness pervaded the garden, which, also, so far as Europeans may judge, was characteristic. In any case it included the conventional temple, while the Seat of Honour, Prayer Stone and other essentials were included. The grassy hills and mounds were well-balanced, and almost all the trees and shrubs were of Japanese extraction.

At first sight, the garden which Messrs. William Cutbush and Son made gave the impression of being the featured golf putting-green beautiful, but it was much more than that. The influence was obviously Japanese. In the distance, green-capped hills yielded a tumbling stream which became a placid pool margined with Primulas, Spiraeas, Funkias, Brooms and other flowering shrubs and plants. The surrounding undulations were well handled, and the spacious shrubbery borders were valuable features.

An especially bright and effective garden was designed and planted by Messrs. J. Cheal and Sons. A central, rectangular lawn, bordered with flagstones and flanked with formal beds of the delightful dwarf Polyantha Roses, led to an ornate, brick-pillared pergola with an Andalusian well. Ample climbing Roses and Vines festooned the pergola, and behind was a generous border of flowering shrubs. The garden was bounded with long borders of various flowering shrubs, including a good variety of Japanese Azaleas, and such border plants as Astilbes, Verbenas, Funkias, Ranunculuses and Primulas.

The En-Tout-Cas Co. had a neat and pleasing garden with a tiled garden house on a raised terrace and borders of Mollis Azaleas. There were also a sunken lawn and an attractive curved pool.

The country garden made by Messrs. Baggesen included many appropriate features, such as the Heather-thatched corner seat, the dove-cote, the pump and trough, and the bee-skep. A winding stream with agreeable planting and borders of flowering shrubs were all in pleasant association.

A prim formality was the keynote of the garden laid out by the Garden Services. Paved paths and terraces, a semi-circular pool, level lawn and a rectangular garden house were the principal features, and these were enclosed by regular, undulating brick walls and borders of evergreen trees and shrubs.

A circular, thatched garden house, set in a curved stone terrace, with timber surrounds gave unto a pool into which a pair of gargantuan toads spouted streams of water, were the dominant feature of the garden of Messrs. Wallace and Co. (Fig. 196). Wistarias set in front of the garden house were singularly effective, while sufficient colour was provided by Azaleas of the various types, Rhododendrons, Brooms and Japanese Maples. There was a good background of evergreen shrubs, and in the corner behind the terrace were large specimens of Rhododendron and Magnolia, all in full bloom.

A pleasant and restful, yet flowery, garden was contributed by Messrs. W. H. Gaze and Son. The plaster-faced flint walls, lightly veiled with climbing Roses and Vines, and the well-filled flower borders, gave an old-world established air to the garden. The sunken centre contained a smooth green lawn and low retaining walls supporting an excellent border of blue and mauve flowers. As befits an exhibition garden, one end was open to provide a view of the whole; this had a neat Yew hedge, while at the further end the wall was broken by an artistic and handsome hammered iron gate.

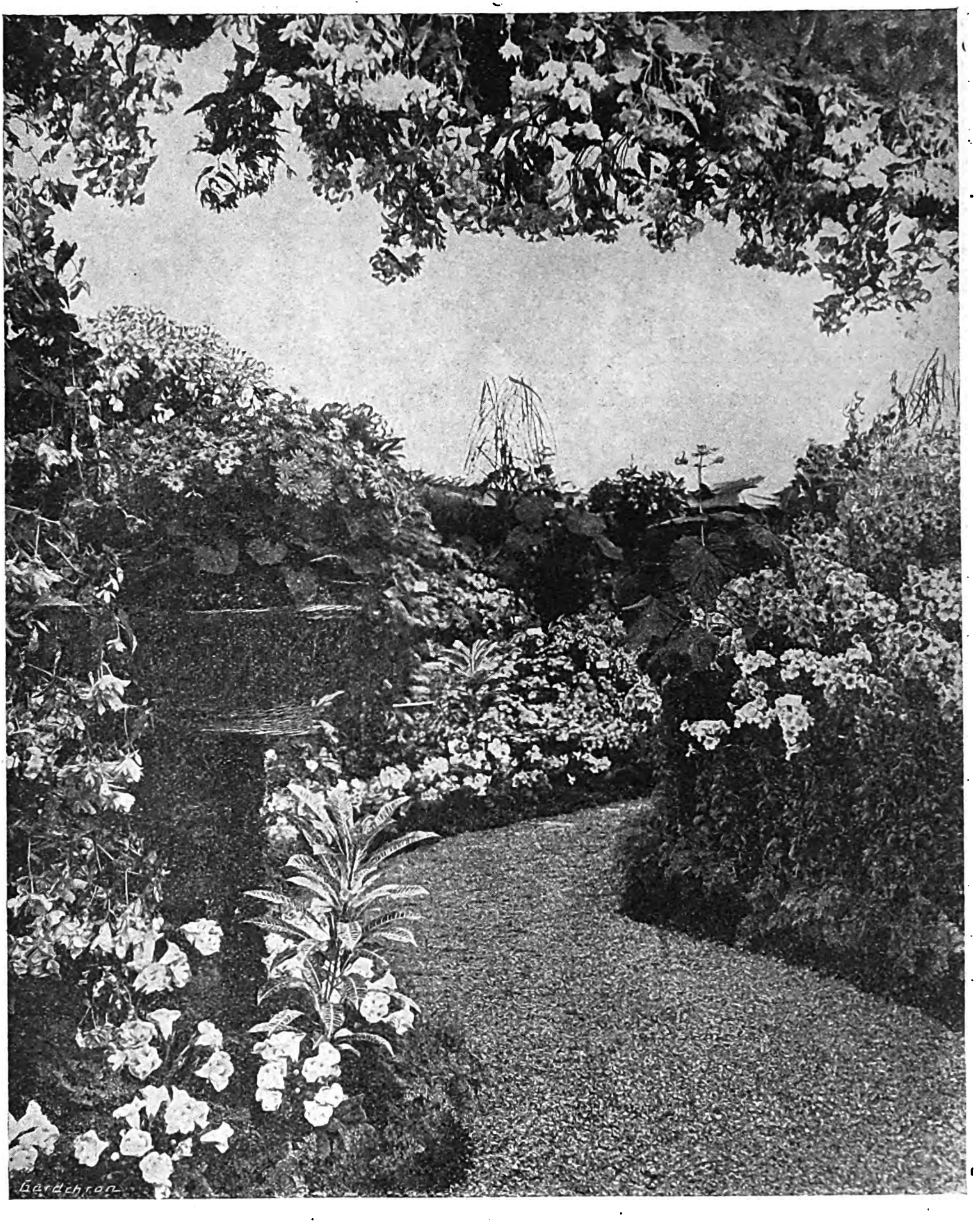

FIG. 197.—CHELSEA SHOW: PART OF MESSRS. SUTTON AND SONS' GROUP, AWARDED THE SHERWOOD CUP AS THE MOST MERITORIOUS EXHIBIT.

Irises.

Among the most charming displays in the tents was the Iris garden, in the form of a large circular bed and two triangular ones, flanked with turf, arranged by Messrs. G. Bunyard, and Co., Ltd. The circular bed was composed of numerous well-flowered plants of such lovely sorts as the lavender-blue Lady Foster, Yeoman, Misa, the popular Prospero, large and beautifully coloured; Magnifica, rose-lavender, with reddish-purple falls; Rosalind, lavender-pink; Luna, Glamour, Thuban, a new seedling, pale lavender-blue with purplish falls; Capella, also new, and Ambassadeur. In the triangular beds, an outstanding seedling was Merope with strong, erect stems bearing large flowers, with smoky maroon-tinted, pale standards, and velvety, reddish-purple falls; other good sorts including 27th Avril, the delicately coloured Souvenir de Letitia Michaud, Tenebrae, Flaming Sword, Vanessa, smoky-yellow with reddish-purple shaded falls, and not two feet high; the lovely Corrida; Lorely, Evadne, of exceptionally delicate shading, purplish-pink, light and suffused with gold; Princess V. Louisa, Amber, Leonata, Asia, and the richly-coloured, purple Souvenir de Madame Gaudichau. The above-mentioned represent but a few of the choicest where all were choice and of great merit.

Irises were included in Messrs. Wallaces' magnificent display of various subjects, two triangular beds being devoted to them, and both Flag and bulbous sorts being represented; among the former were Darius, Quaker Lady, Musa, pallida var. dalmatica, Sapphire, very good; Conchobar, Bruno, Sindjhat, the small flowered, golden Mrs. Neubronner; Souvenir de Mdme. Gaudichau, Duke of Bedford, Georgia, Germaine Perthuis, and Duke of Bedford, while the bulbous Irises embraced numerous varieties in shades of white, blue and yellow.

Bearded Irises were not in evidence in the display set up by Messrs. George G. Whitelegg, the lateness of the season probably being responsible for their absence; nor were they very abundant in the group of Irises from the Orpington Nurseries Co., Ltd., their place being taken by bulbous Irises, which, however gave colour to the displays.

The Bearded Irises in the former group embraced Ballerine, Ann Page, Seedling No. 37d, Lord of June, Halo, and a few others, the bulbous sorts displayed being British Queen, white; Imperator, Baron von Everdingen, white and yellow; and Cajanus, golden-yellow.

Irises of the Pumila section, including such free-flowering sorts as I. pumila var. cyanea, I. p. var. Snowcap, and I. p. var. Orange Queen, were included in the Orpington display, good Bearded sorts being Fro, Wedgwood, Tenebrae, Marquisette, Shekinah, Harmony, Magenta, Duchess Sarah and Gabriel, all very choice; among the most striking bulbous varieties we noted Cornelia van Everdingen, Yellow Queen Imperator and White Excelsior.

Carnations.

The Carnation specialists were again responsible for a grand display of these popular flowers, several magnificent groups attracting a great deal of attention.

As usual, Messrs. ALLWOOD BROS. were represented by a grand exhibit which comprised a circular mass of Perpetual-flowering Carnations, and two charming, triangular beds, supported by rock walls, of Border and Allwoodii sorts. Fine blooms of Maud Allwood, in massed formation, formed a central pillar in the display of Perpetual-flowering sorts, while the hanging baskets and large vases of the fragrant Mrs. A. J. Cobb, in splendid condition, added charm to the display. Wivelsfield Buttercup, Laddie, Mary Allwood, Wivelsfield Claret Improved, Rapture, Red Laddie, very fine, Guy Allwood, Spectrum and Circe Improved, now recognised as among the élite of the section, were shown in perfect condition, Guy Allwood, a lovely salmon-pink, being worthy of special note. White varieties were prominent in White Pearl and Wivelsfield White, while other good sorts which made special appeal were Shot Silk, Topsy, Butterfly, white, flecked red; Edward Allwood, Lady Hindlip and Harmony. Among Dianthus Allwoodii varieties, and they were many, we noted Madge, Beatrice, with comparatively large, bright pink blooms; Ann, Peggy, Joan, Prudence, palest shell-pink; Harold, pure white; Alfred, also white; Bryan, Pat, rich rose-red; Sybil, light pink; Barbara, Esther, Betty, pure white, with a red central zone; Maud, pale salmon-pink, and Sylvia; while among the many beautiful Border Carnations in this attractive display were Mary Murray, primrose-yellow; Lieut. Shackleton, Elaine; pure white; Grenadier, scarlet; Glamour, primrose-yellow; John Knox, deep crimson; Bookham White, Border Yellow. Rosetta, rich rose-pink; Peach Blossom, Orangeman, and Sussex Morn, Sussex Avondale, Sussex Scarlet, Sussex Pink, Sussex Old Rose, Sussex Yeoman, Sussex Purple and Sussex Maroon, classed as Perpetual Border Carnations. Also included in this exhibit were dwarf alpine pinks, among the most floriferous and attractive being Ariel, Wendy, Tinkerbell, Oberon, Pan and Titania. A very meritorious display. Messrs. Allwood Bros. also had a small group of specimen plants of their annual Sweet Wivelsfield, a plant with a future.

Messrs. LOWE AND GIBSON, LTD., had a charmingly arranged display of hardy Border Carnations, in many beautiful sorts, including Mary Murray, Eldorado, Border Yellow, Ida Gray, Royal Clove, Bookham Scarlet, Victory, Lady Hermione, Idwen, Mrs. J. L. Gibson, Linkman, Elaine and Bookham Rose, in such exquisite and varied colour shades as to make description extremely difficult; while Mr. C. H. HERBERT had a small collection of choice garden Pinks, among which we noted Othello, rich crimson and delightfully fragrant; Delight, pale salmon-pink; The Bride, pure white; Cupid, May Queen, Jester, Mrs. Herbert, Prince of Orange, large, bright salmon-pink; Falcon, Supreme, Cerise Queen and Model.

Perpetual-flowering Carnations were attractively staged by Messrs. STUART LOW AND Co., the centre of their large bank of magnificent blooms being composed of the beautiful pink Eileen Low and the rich crimson Philip Sassoon; other grand sorts being Spectrum, R. A. Nicholson, a bright scarlet 1929 novelty; White Pearl, Brilliant, Thomas Ives, Happidais, Topsy, Mrs. Ward Improved, and the lovely Malmaison, Mrs. Charlotte Knollys.

At one end of the second tent, Messrs. C. ENGELMANN, LTD., had a large, semi-circular bank of Perpetual-flowering Carnations of commanding appearance. At the back were enormous vases of such lovely sorts as Rouge, Laddie, Orange Sunstar, Topsy, Saffron—which occupied pride of place in the centre—and Red Laddie, while dotted about this exhibit were lovely vases of Mab, Hebe, Nigger, Citron, Spectrum, Circe Improved, Coral Glow, Sunny and Startler, the foreground being composed of such choice sorts as Ivory, white, with fimbriated petals; Yankee Girl, Velvet, Paleth, Wanda Mary Allwood, Arctic, Aviator, Marchioness of Salisbury, Wivelsfield White, Mrs. A. J. Cobb, Sceptre and Improved Ward. A very charming display, deserving of much praise.

Another attractive group of Carnations was set up by Messrs. KEITH, LUXFORD AND Co., who made special features of White Wonder, Topsy, Cupid, Coquette and Enchantress Supreme, other good sorts being Spectrum, Improved Ward, Saffron, Edward Allwood, Spectrum, Sir Philip Sassoon and Mikado.

Sweet Peas.

In the view of many experts the season has been far from favourable for Sweet Peas, both those grown under glass and the out-of-door plants; but taking the magnificent spikes which were shown at Chelsea as a criterion, their fears were unfounded, for the many blooms were of superb quality.

A magnificent stand of Sweet Peas was set up by Messrs. ROBERT BOLTON AND SON. A fifty feet run of space was filled with flowers of scintillating loveliness and of surpassing excellence. The varieties of orange colouring were very prominent, and these included Gold Crest, Mammoth, Colorado, and a beautiful seedling. The pink shades were well represented by Royal Pink, Cambria, Beatall, Magnet, and the glowing Mrs. A. Searles. Bluebell and the paler Powerscourt, with the richly-coloured Royal Mauve gave the needed deeper tone, and the essential white was the variety Model.

The prominent position in his collection was given by Mr. J. STEVENSON to the vivid variety Lustre. Other sorts of moment were Honour, the well-known Bullion, Purity and Treasure, while at one end were several large bowls of the beautiful Charm.

A pleasing display of Sweet Peas was made by Messrs. ALEX. DICKSON AND SONS who had large stands of Hawlmark Salmon Pink, George Shawyer, Mrs. A. Searles and Hawlmark Cream. Other good varieties in this collection were the purple Olympia, Grenadier, of rich scarlet colour, the lavender Powerscourt, that good garden variety Pinkie, Gold Crest and the Picotee-edged Sunkist.

A memorable display of Sweet Peas was arranged by Messrs. DOBBIE AND Co. Among the novelties were Idyl, cream-pink; Miss Delight, of the palest salmon-pink shading, and Clarion. In the middle background three vases of Pinkie well illustrated its great decorative value, while separated from it by the creamy Daffodil was a glowing mass of Flamingo. At either end were vases of Royal Sovereign, perhaps the richest orange variety, and the nearly perfect Bluebird; other varieties worthy of more than passing attention were Mary Rose, Hero, Lilac Queen, Charming, Prince of Orange, Youth, Magnet, Powerscourt and many more.

In their charming general exhibit, Messrs. CARTER AND Co. included many vases of beautiful Sweet Peas. Of the many excellent varieties we especially admired the rich orange Royal Sovereign, the purity of the white Invincible, Mandalay, of glowing rose-purple shade; the dazzling scarlet Grenadier, the pink-shaded Magnet, and the mauve Princess Patricia

Roses.

These, like the Orchids, had a tent specially devoted to them, an arrangement which again met with general approval, for the Rose tent presented a very attractive appearance, with beds of Polyantha sorts down the centre, and the walls lined with banks of, in most instances, blooms in very good condition.

The beds in the centre—two large rectangular ones—were laid out by Messrs. W. CUTBUSH AND SON, LTD., and were charming, consisting of numerous small beds, in formal design, each filled with magnificent specimens of floriferous Polyantha Roses, with here and there, rising above them, shapely standards of the same varieties, noteworthy among which were Juliana, flesh pink; Mrs. A. Hudij, flaming orange-scarlet; Chatillon Rose, Madame A. Kluis, deep rose; Yvonne Rabier, white; Ellen Poulson, Magnifique, Else Poulson, Lindbergh, bright salmon-pink; Scarlet Leader, Sunshine, Kersbergen, scarlet; Rudolf Kluis, bright red, and the brilliant Golden Salmon.

The corner group of Roses from the MADRESFIELD GARDENS, LTD., consisted chiefly of Polyantha varieties, such grand sorts as Lady Reading, Golden Salmon, Princess Juliana, Magnifique, Edith Cavell, Orange Perfection, Mary Casant, Locarno and Kersbergen, being well represented, while notable sorts, also Polyantha varieties, included in the charmingly arranged, floriferous group set up by Mr. J. H. PEMBERTON, included Magnifique, Edith Cavell, Kersbergen, Golden Salmon, White Echo, Superba and Ideal, with good standard specimens of the above varieties, together with Orleans, Lady Reading, Fratcheur and Ellen Poulson.

Messrs. DE RUITER showed specimen plants of the vivid, salmon-scarlet coloured Polyantha Rose Gloria Mundi, and Messrs. A. REEVE AND Co. had good plants of a fine salmon-pink dwarf Polyantha variety named Little Miss Dorrit.

Mr. GEORGE PRINCE included numerous Polyantha sorts in his group, which also contained excellent blooms of Shot Silk; the beautiful large, white-flowered Elizabeth Arden; Dame Edith Helen, Pax, Madame Butterfly, and the *Daily Mail* Scented Rose.

Mr. ELISHA J. HICKS arranged a very attractive exhibit in the form of mounds of Polyantha Roses, such as Golden Salmon, Minnie Kersbergen, Superba, Orange King and Frank Leddy, rising from a foreground of grand blooms of such lovely sorts as Dame E. Helen, Craigwell, Golden Gleam, Sunningdale, Mrs. Henry Morse and Charles P. Kilham. Rising above these were pillars of Mamam Cochet, White Maman Cochet, Mrs. F. Hobbs, and Lady Plymouth, while at the back were various grand specimen climbing sorts.

Another grand display of Roses was that arranged by Messrs. B. CANT AND SONS, LTD., who had a large corner bank of blooms. The background was of rambler sorts, and in front of these were massed heavily-flowered bushes of Hilda, Mrs. Beatty, Padre, Lady Wakefield, Madame Butterfly and Roselandia, while the front of the exhibit was lined with grand blooms of such choice Roses as Giant King, Phoebe, Covent Garden, Sovereign, and the large-petalled, single, golden-flowered Cecil.

In Messrs. CHAPLIN BROS.' enormous group, the background consisted of grand specimens of such excellent rambler Roses as Hiawatha, Dorothy Perkins, White Dorothy Perkins and Chaplin's Pink Climber. There were splendid standards of Excelsa and Lady Gay, and large mounds of W. E. Chaplin, Lady Inchiquin, Conqueror and others, while the groundwork of the display was of massed, floriferous specimens of dwarf Polyantha sorts, notably White Echo, Kersbergen, Golden Salmon, very fine, Locarno, Ideal and Lindbergh.

Messrs. WALTER EASLEA AND SONS, LTD., had a charming display on tabling, with ramblers at the back, the notable sorts being Red Explorer and Dorothy Perkins, while among the standards, the specimens of Orleans and La Reine Elizabeth were very fine, as also was the central mass of the dwarf Polyantha Golden Salmon, together with large vases of Charles P. Kilham, Florence Izzard, Florex and Mrs. Beckwith.

In the massed bank of Roses set up by Messrs. ALEX. DICKSON AND SONS, LTD., the most striking sorts, of which there were large baskets of specimen blooms, were Lucie Marie, Gladys Berskin, Swansdown, Edith Nellie Perkins, Flamingo, Imprés, Barbara Richards, which received an Award of Merit, and the beautiful, yellow-flowered Canary.

One of the grandest exhibits in the Rose tent was the display arranged by Messrs. FRANK CANT AND Co., in the form of a long bank, with Ramblers as a background, most attractive among these being Excelsa, Mary Hicks and Minnehaha. They had grand bushes of Mrs. A. R. Barraclough, Lady Inchiquin, Lady Forteviot, Margaret McGredy, Sir David Davis, Shot Silk, Patience and Mabel Morse, while the front was lined with Polyantha sorts, such as Golden Salmon, Kersbergen, White Echo, Paris, Superba and Orange Perfection. A very charming group.

Ferns.

Mr. **Amos Perry** was, as usual, the only exhibitor of Ferns, but his group, in the form of a square mound, crowned with grand specimen plants of such beautiful Ferns as Struthiopteris pennsylvanica and S. germanica, both with large, gracefully-spreading fronds, was very attractive and refreshing in its cool appearance. It included several of the beautiful Lastreas, notably L. japonica, L. felix mas var. fluctuosa gracilio, L. f. m. var. cristata, L. f. m. var. crispa; Royal Ferns such as Osmunda gracilis and O. regalis var. purpurascens; and other choice Ferns, notable among which were Adiantum pedatum, Athyricum plumosum var. elegans, O. p. var. polydactylum, A. regale, A. gemmatum, A. cristatum var. purpurascens, A. Craigii, A. setigerum var. cristatum, A. densum and A. laciniatum var. ramulosum, Polystichum aculeatum var. acutilobum and Adiantum flabellatum.

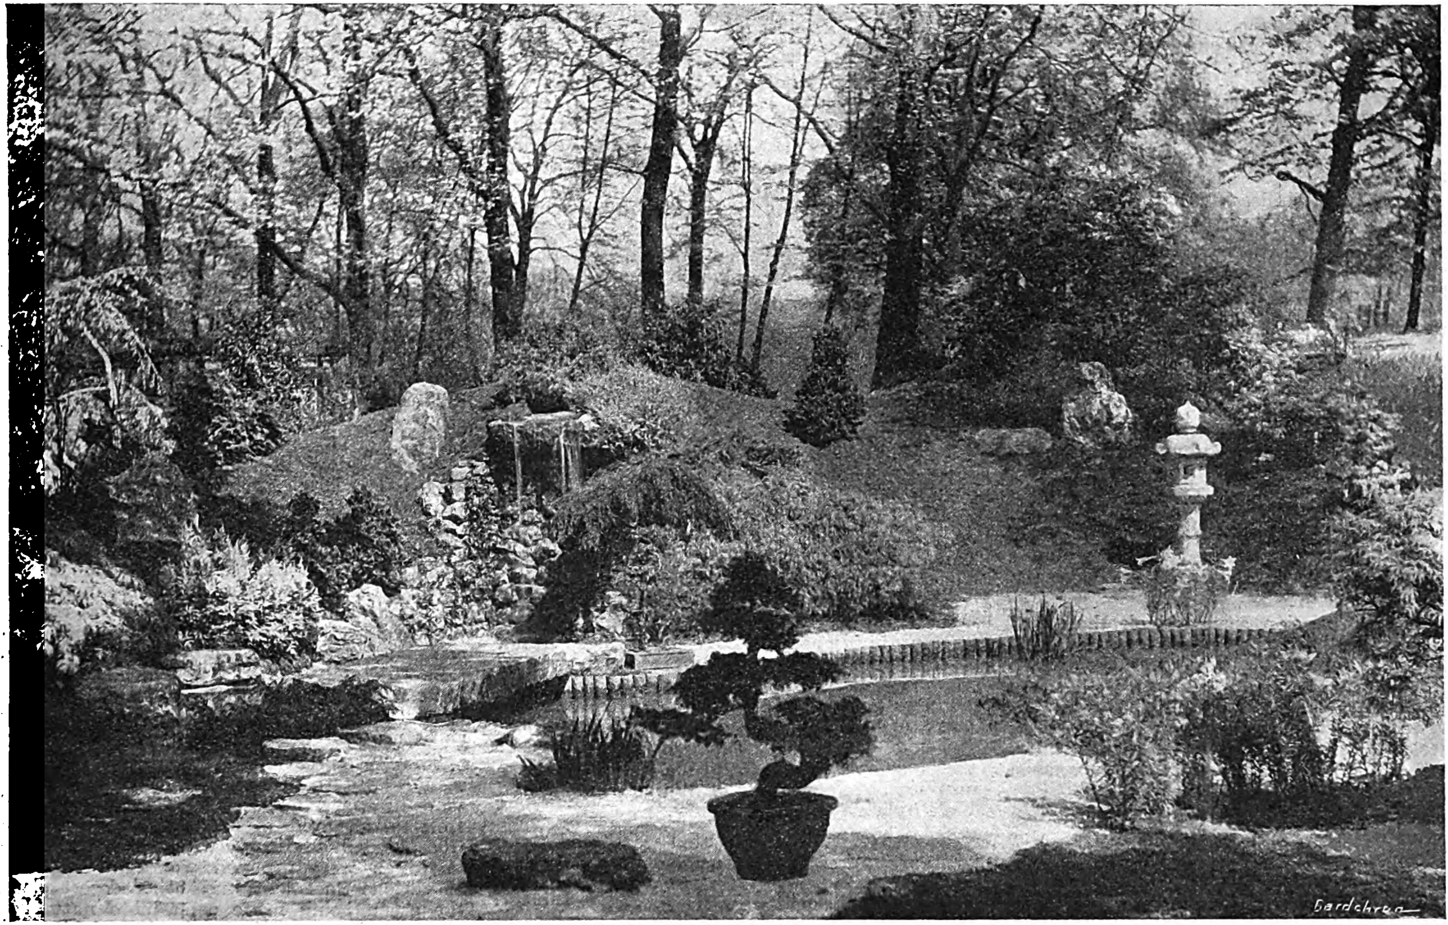

FIG. 198.—CHELSEA SHOW: MESSRS. W. WOOD AND SON'S JAPANESE GARDEN.

Rock Gardens on Tables.

In the history of Chelsea Shows nothing, perhaps, has shown greater development than the displays of rock gardening, and this remark applies equally as much to the displays on tables in the tents as to the larger demonstrations in the open. When one compares the way in which alpines used to be displayed at the shows in the Temple Gardens with what is now seen at Chelsea, the improvement can be fully appreciated, and the artistic arrangement displayed appealed particularly to those who have to be less ambitious than their fellows in the possession and furnishing of a rock garden, insomuch as they have to be content with something small.

There was a marked boldness about the display set up by **Lady Aberconway** and the Hon. **H. D. McLaren**, Bodnant, Tal-y-Cafn, North Wales, and here choice Rhododendrons, including R. Wiltonii and R. callimorphum with Azaleas Vaseyi and others were used as a background. In front, weathered stone was used with pleasing effect to make more natural the appearance of clumps of Meconopsis grandis and integrifolia, and Primula schionantha and P. Brownii, Cypripediums californicum, pubescens and others. It is not surprising that this extremely interesting exhibit of flowers, many of them rare, attracted a considerable amount of attention.

There seemed to be rather a shortage of flowering plants, and too many of the Coniferous family in the space occupied by Messrs. **John Scott and Co.**, and despite the tasteful placing of the natural stone used, the exhibit had rather a sombre appearance, which would have been obviated by the inclusion of more flowering subjects.

A good deal of taste was displayed by Mr. **Gavin Jones** in the arrangement of his rock garden. Stone was used in quantity without being overdone, and an ancient-looking Fir tree in the centre seemed to be by no means out of place. Peeping out of the pockets between the rocks were dainty little Phloxes, Primulas and Violas, with which the dense blue of Gentiana acaulis made a pleasing contrast. This is to mention only a few of the dainty little rock plants included in the exhibit.

Rather flat was the impression given by the rock garden arranged by Messrs. **W. E. T. Ingwersen, Ltd.**, and the stone employed looked as if it lacked the influence of the weather. The flowering plants and tiny Conifers were, nevertheless, nicely arranged, dwarf Phloxes, Primulas and Violas being particularly noticeable.

Mr. **G. Reuthe** set up a rock garden which did him infinite credit, and the way in which moss-covered stones, Conifers and flowering plants were arranged made the exhibit an extremely attractive one. Amongst the many things displayed were clumps of dwarf Azaleas and Cytisus kewensis, Irises in variety, Phlox setacea vars., Brightness and R. C. Chambers, Trollius in variety, with dainty little Saxifragas, Violas and many interesting gems of the alpine family.

Messrs. **J. Cheal and Sons, Ltd.**, occupied one side of a table with a choice collection of alpine plants interspersed with stones and making a pleasing colour effect. Aubrietias in variety were very pleasing, and the same can be stated of the Phloxes in variety, miniature Irises and Gentians. There was much indeed in this comparatively small display to interest any lover of rock plants.

A graceful Japanese Maple in the centre was a feature of the rock garden arranged by Mr. **G. E. P. Wood**, and around it, arranged in pleasing manner, were groups of many interesting plants which included Linum Lewisii, dwarf Irises and Phloxes, Aubrietias in variety, Verbenas, Violas in different colours, and the tiniest of pink Roses. Considered from any angle, this display stood out as being one of the most effective.

Messrs. **Tuckers, Ltd.**, used natural stone and granite chippings quite effectively in setting out their display of rock plants, among which were Primula japonica and others, Saxifraga, primuloides and S. Diana, Asperula suberosa, Polemonium reptans, Androsace lactea, Phlox Nelsoni, and the white Iberis Little Gem. Among the taller subjects, Aquilegia alpina and Phlox divaricata var. Laphami were used with pleasing effect.

Primulas of hardy character were the main feature of the bold display made by Messrs. Oliver and Hunter, and among the species were P. japonica, P. chionantha and P. sikkimensis. Meconopsis betonicifolia, and integrifolia made a pleasing display, and the rare Primula Giraldiana alba called for special comment. In clumps surrounding the extremely interesting collection of Primulas were many choice and dwarf alpines.

There was something daintily effective about the manner in which Mr. K. Therkildsen set up his small collection of plants amid stones and small chippings. Primula cortusoides, Aquilegia glandulosa, Saxifraga Cotyledon var. norvigica and Primula japonica were among the features of the exhibit, and another was that all the names were so plainly written that they could be easily read. Some of the exhibitors of alpines might take a hint from this. The Owermoigne Nurseries occupied a small space of tabling, with a collection of interesting plants in which Irises lutea and I. gracilis, Anemone fulgens and Armeria Merlin were quite effective.

The choice little Phloxes subulata rosea, Alice Wilson, Vivid, Little Dot and others were, in themselves, a feature of the interesting rock garden which was arranged with taste by Messrs. Maxwell and Beale. Other plants which attracted attention were Lithospermum Heavenly Blue, Achillea King Edward and a collection of hardy Primulas and Dodecatheons.

Messrs. W. Keep and Co. made a bold display with Violas in the pink of flowering condition, some of them in mass and others arranged among the stones which formed the rockery. One of the most effective of the latter was the very free-flowering, yellow Golden Wave.

There was a striking boldness about the way Messrs. Wells, Junr. arranged their rock plants in masses with not too much stone showing. Among these masses were Potentilla fragiformis, very effective, Lithospermum Heavenly Blue, Aubrietias The Queen and Lilac Queen, Gentianas verna and acaulis, Phloxes Samson and Douglasii, and nivalis, as well as alpine Poppies, Violas Clarence Elliott and Black Knight, Mimulus Whitecroft Scarlet and Primulas chrysopa, secundifolia and sibirica.

Alpine plants never seem to look their best when shown in pots, but nevertheless a good deal of the material which comprised the exhibit from C. Kirch, Esq., Beckenham, Kent, was extremely interesting. Particularly so were the many different and charming varieties of Androsaces, Saxifragas, Oxalis and Gypsophilas. In fact, the word choice seemed to be written all over this display.

Except that it was a little flat, the rock garden displayed by Messrs. M. Prichard and Son was very pleasing. Plants in bewildering variety were included and somewhat out of the common were Kalmia glauca, Lithospermum intermedium, Potentilla aurea, Edraianthus serpyllifolius var. major, Gazania montana, Haberlea rhodopensis and Rosa pumila alpina. Summed up in a few words, there was a wealth of material in this exhibit to interest lovers of rock plants.

Blocks of weathered stone were liberally and naturally used in making the rock garden from Messrs. Clarence Elliott, Ltd., but to state that the expanses of green moss with single plants made to look as if they were growing in it, were rather overdone, is only fair criticism. Very natural, however, were the little clumps of Phloxes Vivid, Douglasii, var. Lilac Queen, while Sempervivum Arachnoideum and Androsace Laggeri filling up crevices between stones, as well as Sedum spathulifolium purpureum, looked exactly as if they had grown there.

Japanese Maples, Azaleas and Cytisus in variety formed the centre of the display made by Messrs. Bowell and Skarratt, and sloping down to the edge of the table on either side were many dainty plants, noticeable among which were Polygala calcarea, Tulipa Batalinii, hardy Primulas, Cypripedium pubescens, Polemonium reptans, Phloxes and Saxifragas.

In the semi-rock garden exhibit which came from Messrs. Barr and Sons there were collections of Irises, including Curiosity, Burgundy, cristata, Ditton Purple and others, as well as Aquilegia glandulosa, Dodecatheon Belle Mauve, Polyanthuses, Aubrietias, Saxifragas and Trollius grandiflorus, the whole making a highly pleasing display.

Messrs. G. A. Clark occupied the end of one table with an exhibit which would have been more effective if it had been a little less crowded. Features in the display were Daphne Cneorum major, Meconopsis Baileyi and Phlox canadensis. A collection of little alpines in small pots which were only partially hidden by green moss was shown by Messrs. H. W. Jeans and R. M. Pritchard, but the method of the arrangement did not add to the attractiveness. A mass of Phlox Douglassii var. Lilac Queen and another of Cardamine pratense plena were the chief features.

There was a familiarity about the stones used and the way the plants were arranged among them, in the rockery set up by Messrs. Backhouse which was small but highly pleasing. The dainty Cyclamen repandum album was shown to very great advantage, and other features were Gazania splendens, Primula Forrestii and Viola gracilis var. lutea.

Messrs. Bakers set up an exhibit which was well worthy of their reputation. Conspicuous in it were fine specimens of Primulas Florindae, chionantha, Red Hugh, secundiflora, Veitchii, Wardii and others, and interspersed among them was a great variety of charming and popular plants, not the least interesting of which was Pentstemon Scouleri.

Mr. H. Hemsley filled one side of tabling with a mixed exhibit in which Rhododendrons, Azaleas and Japanese Maples formed a background, with alpine plants in variety arranged in front. The collection of alpine plants set up in bank-like form by Messrs. Carlile made a bright show, but it seemed as if an attempt had been made to crowd in too much material.

Masses of the yellow Linum arboreum, Aubrietias gloriosa, Dr. Mules, Church Knowle, Bonfire, with Phloxes Model and Douglasii, Erinus Dr. Harnele, Primula farinosa and Iris cristata, were features in a highly attractive rock garden exhibit arranged by Messrs. J. Waterer, Sons and Crisp, Ltd. Stone was used with effect, and the whole display was highly attractive. Quite a pleasing arrangement of rock plants was shown by Mr. Stephens Sims, and conspicuous in it were clumps of Saxifragas Edna, Sir Douglas Haig, Mrs. E. Piper and sanguinea superba. Iris pumila cyanea was also an attractive feature of the exhibit. Messrs. J. Robinson and Son set up a highly attractive rock garden, the chief feature in which was bold clumps of Iberis sempervirens, Phlox setacea var. atropurpurea, Viola gracilis var. Clarence Elliott and Viola hybrida Crimson Beauty.

Mr. G. G. Whitelegg used weathered stone with very great advantage to make natural and homelike, showy clumps of Phlox Vivid, Saxifraga Pompadour, Iberis Little Gem, Gentiana acaulis, Erinus carmineus, Armeria nana and other favourites. This was a very interesting exhibit.

Saxifraga pyramidalis made an effective centrepiece for a very charming collection of rock plants staged by Messrs. W. Wood and Son. Without being in any way overcrowded, the compact clumps of Saxifraga notata, Primulas Cockburniana, farinosa, and Craven Gem, and Phloxes stolonifera, lilacina, Vivid and Brightness showed to great advantage. Charming also were Anemone sylvestris, Potentilla aurea, and Aubrietias J. S. Baker, Russell's Crimson and rosea splendens.

Messrs. Kent, Brydon and Haigh used considerable taste in arranging their miniature rock garden, the chief feature of which was a clump of the yellow-flowered Primula Barrowby Gem, which was not included in many of the other exhibits. Primula sino-plantaginea was another plant in this collection which attracted considerable attention. Cytisus in variety, dwarf Azaleas, Violas, Primulas, Irises and other plants arranged in a pleasing manner, made up the exhibit staged by Mr. P. Gardner.

Small, but quite unique in character, was the rock garden, with water, set up by Mrs. Milford, Chedworth, Gloucestershire, and the Cotswold stone was used tastefully in making a temporary home for Phloxes, Gentians, Primulas, Incarvilleas and other plants.

While there was nothing out of the ordinary in the plants shown by the Misses K. and E. Hopkins in their rock garden arrangement, the rocks were employed judiciously in giving the exhibit a natural appearance.

Messrs. H. Langridge and Co. are to be commended on the way they used weathered stone in the making of their rock garden, and a pool of water in front had a very natural appearance. Conspicuous among the flowering subjects were Phloxes, Violas, Primulas, Potentillas, Aubrietias and Linum arboreum.

Saxifraga pyramidalis was the chief feature in the rock garden set up by Messrs. W. H. Rogers and Son, but pleasing also were clumps of Iris cristata and choice collections of Sempervirens, Antennarias, Phloxes and Violas.

The Central Garden Supplies occupied the end of one table with a collection of alpine plants arranged in undulating form, but with green moss as a groundwork, and without the use of stone. The display was attractive, as it differed in the character of the lay-out from other exhibits of similar character in other respects.

The stone used by Messrs. Pulham and Son in their rock garden had a very natural appearance, but a few more flowering plants in the crevices would have made the effect more pleasing. In making their rock garden, Messrs. Casburn and Welch used big stones with considerable advantage. The soil was hidden by small granite chippings, and the clumps of Campanula Stevenii, Androsace yunnanensis, Phlox amoena, Asperula suberosa and Viola Bluestone presented a pleasing and natural appearance.

Californian Plants.

Never before has such an exhibit as that staged by Mrs. A. Sherman Hoyt, of the California Conservation Committee of the Garden Club of America, been seen at a Chelsea Show, and nothing but unstinted praise is due to her for her remarkable display, which depicted typical Californian desert scenes, and which was housed in a special tent. It took the form of three sections, each partitioned off, representing, respectively, a "Desert Garden," "Death Valley," (Fig. 195) which is situated in eastern Central California; and a "Redwood Grove." These were so designed as to produce as natural an effect as possible.

The "Desert Garden," for instance, had a scenic background consisting of a composite view of the Armagosa, Mojave, and Colorado Deserts, situated in southern California, and this blended admirably with the actual garden in which were grouped wonderful specimens of various Succulent and other desert plants, the scene being made even more natural by the inclusion of typical animals and birds; in fact, no detail which would add to the natural effect seemed to have been overlooked—in the fore right-hand corner there was the small rock pool, common enough in novels, above which a notice, on a battered board, proclaimed "Poison Water; Beware," and bore the appropriate skull-and-cross-bones. And as to the plants with which this garden was furnished, there were lank, spiny specimens of Candlewood, Fouquieria splendens; large clumps, resting among rocks, of the Cluster Cactus, Echinocactus polycephalus, and tall specimens, of parched appearance, of Yuoca arborescens; with huge Prickly Pears, and several scrubby specimens of the grey-stemmed Creosote Bush, Larrea glutinosa, looking especially parched and lifeless. Other occupants of the desert which assisted in the making of this desert garden. were Atriplex himenelytra; the Organ Cactus, Lemaireocereus sp., Juniperus occidentalis, and the Smoke Tree, Dalia pubescens, described as, when in blossom, "a cloud of rich purple."

"Death Valley" presented an even more arid scene, due to the ground work of colemanite (crude borax), with a salt crater, lime stalactites, and other rock characteristics. Cacti were scattered about sparingly, and occupying a central position was a large Larrea glutinosa, around which prowled two coyotes, while the skeleton of a burro, and other smaller details, completed a scene which blended perfectly with the desert background, the whole being lit very effectively by artificial means.

Lastly, the Redwood Grove was admirable both from a scenic, and an educative point of view. The scene constituting the background represented a part of the Richardson Grove, and gave a very clear impression of the Redwood (Sequoia sempervirens) forest, the exhibit itself adding to the general interest of the scene by depicting the undergrowth met with under such conditions. There were various Ferns—Polystichum munitum, Woodwardia radicans, Gymnogramme triangularis, and the Liquorice Fern, Polypodium californicum, growing luxuriously about seedling Douglas Firs (Pseudotsuga Douglasii) in association with Ledums, in flower; Vacciniums, various species of Arctostaphylos, and numerous other subjects.

Mrs. A. Sherman Hoytis indeed to be congratulated upon the wonderful feature she provided, for the expense and labour entailed in transporting such an exhibit must have been enormous.

Narcissus and Tulip Committee.

Present: Mr. W. B. Cranfield (in the chair), Mr. L. J. Richardson, Mr. F. Herbert Chapman, Mr. W. Slinger, Rev. Rollo Meyer, Mr. W. Poupart, Mr. F. A. Secrett, Mr. H. G. Hawker, Mr. H. Smith, Mr. C. W. D. Needham, Sir A. Daniel Hall, Mr. Peter R. Barr, Mr. G. Monro, Mr. A. White and Mr. A. Simmonds, Secretary.

AWARDS OF MERIT.

Tulip Dorothy Ann.—This variety was exhibited by Sir **Daniel Hall**, Merton, Surrey, as a variety suitable for exhibition and cutting. It is a shapely English Tulip with broad, red segments, with a few white flecks and a white central zone.

T. Lady Ernle.—An early English variety for exhibition purposes, with segments of firm texture, orange-scarlet within, and paler, owing to the "bloom" on the outside. A very shapely bloom. Exhibited by Sir A. **Daniel Hall.**

T. Clos de Vougeot.—This was exhibited as a variety for cutting and garden decoration. It is an attractive Darwin variety, of good form, and with glossy, very deep crimson segments; also shown by Sir A. **Daniel Hall.**

Narcissus Khatmandu.—Exhibited as a Leedsii variety, as a show flower; this dainty Narcissus is pure white, both in the rather small perianth segments, and the frilled, flattened crown, which is, however, shaded in the centre with green. Shown by Mr. **Herbert Chapman.**

N. Triplex.—Another dainty little Narcissus, in this instance a semi-double one, exhibited by Mr. H. **Chapman.** The flowers are pure white, with spreading and slightly waved outer segments, and a flattened inner cluster of small ones.

N. Finality.—A lovely Poeticus Narcissus, with flowers of medium size, composed of slightly reflexed, waved, pure white perianth segments, and a small yellow cup, edged with red. It was exhibited as a variety suitable for cutting by Mr. F. A. **Secrett.**

N. May Glory.—Another Poeticus Narcissus, with oval, pure white perianth segments and a flattened, frilled, rich orange cup. Also shown by Mr. F. A. **Secrett.**

Tulips.

Tulips struck a dominant note in the tents, and among the many exhibits none was so striking as that set up by Messrs. **Barr and Sons**—a magnificent bank of flowers, in grand condition, seventy feet long and embracing some one-hundred-and-eighty varieties. The centre was composed of a mass of the richly-coloured Prince of Orange, with the palest pink Margaret on one side, and Amber on the other, while in front were large vases of Walter T. Ware, gold; Beauty of Bath, Zomerschoon, James Wild, an old English Tulip, flamed yellow and deep maroon, Fantasy and Erguste. To the right were splendid vases of Clara Butt, Ellen Willmott, primrose-yellow; Canada, pure white; Rev. Ewbank, Inglescombe Yellow, Fire Glow and Grand Monarque, while the left wing of this really magnificent display embraced Corydon, Farncombe Sanders, light scarlet and very striking; Capri, pale primrose; Bouton d'Or, golden-yellow; Louis XIV; Argo, orange and yellow; Themis, white; Baronne de la Tonnaye, rose-pink, shaded paler; and several flamed and Parrot Tulips, notably Lola, red and white; and Dainty Maid, reddish-purple and white. A very meritorious exhibit.

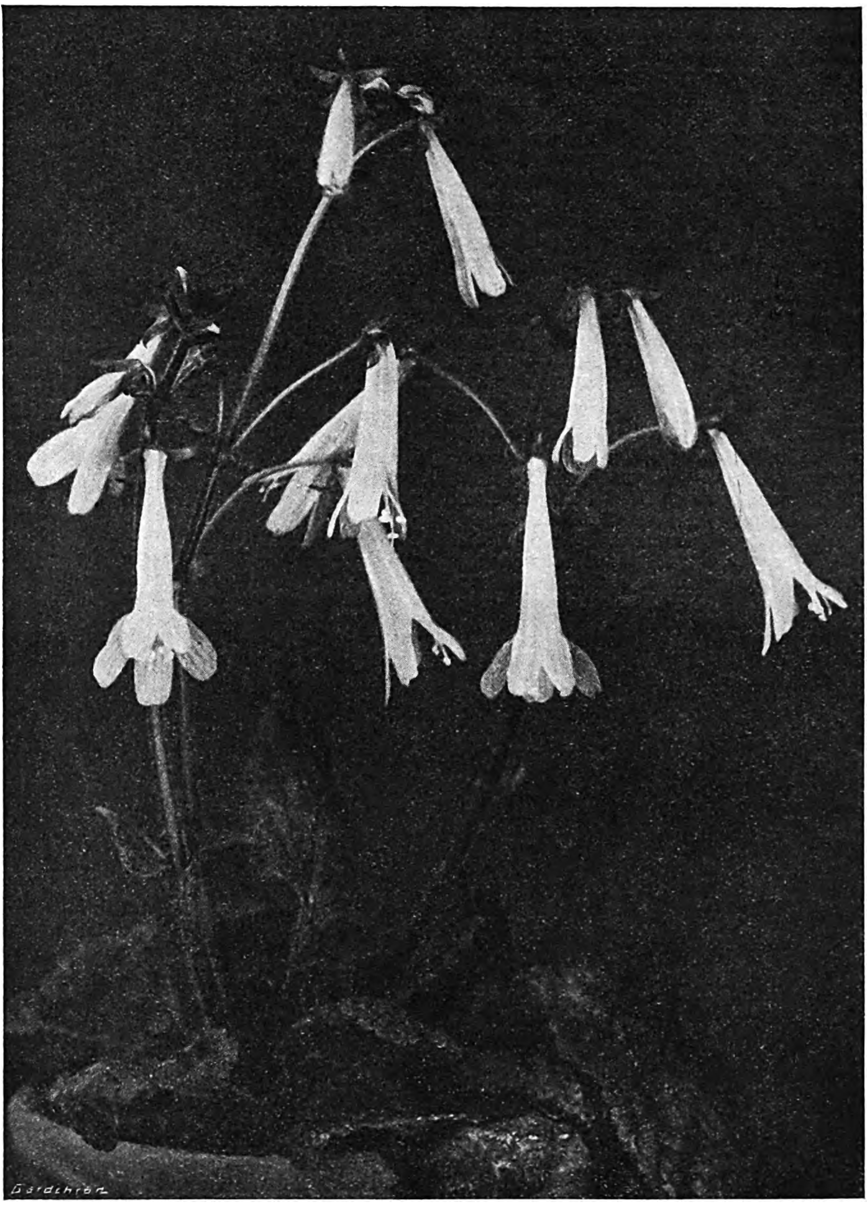

FIG. 189.—CHELSEA SHOW: OURISIA ALPINA.
R.H.S. Award of Merit, May 21. Flowers lilac-pink. Shown by Capt. McEacharn, Galloway House, Wigtownshire.

Another attractive group of Tulips was staged by Messrs. R. H. **Bath, Ltd.**, numerous varieties in many shades being represented by excellent blooms. At the back were tall sheaves of the quaint, bright yellow-flowered Tulip reflexa, together with Valentine, Olive, the scarlet-crimson Adolphe van der Hyde, and St. Simon, while other outstanding sorts in this collection included Le Reve, Inglescombe Yellow, Edith, Sir Trevor Lawrence, Mrs. Moon, Orient, Panorama, Baronne de la Tonnaye, Scarlet Perfection, and Aphrodite.

In the small but choice collection of Tulips displayed by Messrs. D. **Stewart and Son**, several beautiful Cottage and Darwin Tulips were represented, the most striking sorts being Prince of Orange, Amber, Louis XIV, Mrs. Moon and Golden Bronze, among cottage Tulips, and La Tulipe Noir, Rev. H. Ewbank, Viola, and Clara Butt, grand Darwin varieties.

Messrs. G. W. **Miller** had an interesting exhibit, composed chiefly of Tulips, but embracing also Polyanthuses, Trolliuses, such as Orange Princess, Earliest of All, Springfield Beauty, Etna and Queen Mary; Paeonies and various alpine plants, the most striking Tulips being Centenaire, Farncombe Sanders, Pride of Haarlem, and Clara Butt, together with City of Haarlem, Louise XIV, Bronze Queen, Ellen Willmott, Pink Beauty, Henry Clay, Faust, Nectar and King George V.

In the group set up by Mr. H. **Prins**, the three varieties of Narcissus—Fardiva, N. triandrus var. Snowball, and Belle Chinoise—the last-named being a pale biscuit-coloured, distinct Poetaz variety, acted as a foil to the numerous Tulips, noteworthy among which were Taurus, Lord Carnarvon, Oranges and Lemons, Mrs. Moon, Bronze Queen, Yardil, a cream, red-banded Darwin; Parisian Yellow, Vesta, palest primrose; Mississippi, vivid red; Mongolia, Artemis and Ohio.

Mr. **Herbert** G. **Longford** arranged numerous varieties of Tulips, well set off by

Lily of the Valley, bulbous Irises, and a few Narcissi, in a bank of moss and rocks, the outstanding Tulips being the golden-yellow Mr. Damis; Philippe de Commines, dark glossy crimson; Zary, yellow, feathered scarlet; Mrs. Moon, Boadicea, Columbus, Bronze Queen, Prince of Orange, Bronze Queen, and Alaska.

Tulips from Bronwylfa, St. Asaph, were also noteworthy, for, besides Tulipa Gesneriana var. lutea, Marconi, Maryanit, Farncombe Sanders, Zulu, and the lovely white Zwanenburg, in large sheaves, there were excellent vases of Inglescombe Yellow, Louis XIV, Carara, Cardinal Manning, Sophrosine, Mrs. Moon, La Merveille, Loveliness, andnumerous other lovely sorts.

Tulips, in excellent variety and good condition, were charmingly displayed by Mr. Alfred Dawkins, the background of light pillars of such beautiful sorts as William Copland, Farncombe Sanders, Madame Krelage, Laurentia, William Pitt, Princess Elizabeth, White Swan, and Professor Rawenhoff, and the corner pillars of Bartigon and Pride of Haarlem, acting as foils to the grand, yellow-flowered Mongolia, very fine; Louis XIV, Sieraad van Flora, rich rose; vitellina, pale primrose-yellow; Miss Blanch, Le Reve, Leda, Electra and many others, including several double-flowered sorts.

A small group of Tulips, but poorly arranged, was set up by Messrs. J. R. Pearson and Sons, Ltd., their best blooms, of excellent quality, being of Frans Hals, Mr. Damis, Fascist, Afterglow, Grenadier, Prince of the Netherlands, Dido and La Fiancee.

Tulips in splendid condition were also staged by the Rev. H. Rollo Meyer (gr. Mr. J. P. Izzard), Walton Rectory, Hertford, who had vases of grand blooms of Prince Albert, Boadicea, Baronne de la Tonnaye, Quaintness, Lucifer, Dom Pedro, Mrs. Moon and The President, together with Mongolia, Suson, Salaman, T. Gesneriana var. spathulata major, Isis, Inglescombe Pink, and Marconi.

The Welsh Bulb Fields were also represented by a charming collection of Tulips, tastefully arranged, the varieties constituting the background being King George V, Baronne de la Tonnaye, Prince of Wales, Jaune d'Oeuf and Inglescombe Pink, other noteworthy sorts including La Tulipe Noire, Cardinal Manning Louise de la Valiere, Marie Louise, Quaintness, T. Gesneriana var. lutea, Louis XIV., Ronald Gunn and Parisian Yellow.

In conjunction with Long-spurred Aquiligias, St. Brigid Anemones, and a few Irises, Messrs. Daniels Bros. had a bright display of Tulips, consisting of tall pillars of Feu Brilliant, Hamlet, Scarlet Perfection, Vesta, Siren, Mark Graaf of Baden, Zwanenburg, Adonis, Madame Lethiery, Nectar and other brilliantly coloured sorts, rising above baskets of grand blooms of Gen. de Wet, Pink Beauty, Don Pedro, Feu Ardent, Golden Bronze, La Tulipe Noire, Orient, Garibaldi and Preciosa, the whole making a very attractive display.

Fruit and Vegetable Committee.

Present: Mr. A. H. Pearson (in the chair), Mr. H. S. Rivers, Mr. J. Cheal, Mr. F. Bostock, Mr. J. Wilson, Mr. R. H. Hall, Mr. H. Prince, Mr. H. Basham, Mr. E. Neal, Mr. A. Bullock, Mr. G. Weston, Mr. F. Jordan, Mr. W. J. Earl, Mr. A. Poupart, Mr. H. V. Taylor, Mr. Fred G. Treseder, Sir W. H. Lobjoit and Mr. A. N. Rawes, Secretary.

The only exhibit before this Committee was a new Tomato, called Bide's N.C.O., well-fruited plants of it being exhibited by Messrs. Bide and Sons, Ltd. It was recommended by the Committee for trial at Wisley.

Vegetables.

No Chelsea Show would be complete without a display of vegetables by the Hon. Vicary Gibbs, Aldenham House, Aldenham, and the magnificent collection by which he was represented on this occasion did much to emphasize the skill, both as an exhibitor and a grower, of his gardener, Mr. Edwin Beckett. Few vegetables and salads were not represented, and many uncommon subjects were included, such as the Morel (Morchella esculenta), the Red Currant Tomato, numerous ornamental Beans, Egg Fruits in several varieties, and Ornamental Peas. There were grand heads of Broccoli, Tomatos in many varieties; Cucumbers of perfect form; Rhubarb, Mushrooms, Potatos, French Beans, also in numerous varieties, Marrows, Peas, Turnips, Spinach, Broad Beans, Capsicums, Carrots, Lettuces, Oxalis tuberosum, Aubergines, Kohl Rabi—in fact, few vegetables or salads would appear to have been omitted from this marvellous display. This was the only exhibit of vegetables in the show.

Fruits.

Originality was the keynote of the display of Apples set up by Messrs. G. Bunyard, Ltd., the black cubes upon which the Apples were perched suggesting an attempt to produce a futuristic effect, a style of exhibiting not to be encouraged. However, the Apples themselves were in splendid condition and worthy of note, having been stored, according to a small notice, in a thatched, wooden fruit room, without ice or other artificial cooling. The varieties displayed, as stated, in excellent condition and beautifully coloured, were Blenheim Pippin, Cox's Orange Pippin, Upton Pyne, John Standish, Rosemary Russet, Orlean's Reinette, Wagener, Claygate Pearmain, Belle de Boskoop, William Crump, Edward VII, Reinette du Canada, Newton Wonder, Mornington Pearmain, Brownlees's Russet, Adam's Pearmain, Barnack Beauty, and several others, all excellent for so late in the season.

Strawberries were shown by Messrs. Laxton Bros., who had large mounds of fruiting plants of King George, Duchess of York, and The Duke, the two last-named appearing to be very heavy croppers; and appetising baskets of perfect fruits of, besides those mentioned above, Maréchal Foch, Laxton's Primate, and Acquisition—a splendid exhibit, portraying the very acme of Strawberry culture

Pot fruits, embracing Nectarines, such as John Rivers and Cardinal, of both of which there were several well-fruited specimens; Peaches, notably Duke of York, and a seedling (Kestrel Peach × Lord Napier Nectarine); and Citruses in variety, were exhibited by Messrs T. Rivers & Sons, the group also containing excellent specimens of several varieties of Plums and Cherries, among the latter, Guigne d'Annonay being specially worthy of note.

Messrs. Bide & Sons exhibited fruiting plants of their new Tomato, Bide's N.C.O., a strong growing, heavy cropping, red-fruited variety, carrying large trusses of well-shaped fruits of medium size.

Awards by the Council.

CHALLENGE CUPS.

The Sherwood Cup.—For the most meritorious exhibit in the Show.—To Messrs. Sutton and Sons, for greenhouse plants.

The Cain Cup.—For the best exhibit shown by an amateur.—To Lady Aberconway and the Hon. H. D. McLaren, for a mixed group of less common plants.

SILVER CUPS.

To Messrs. Dobbie and Co., Ltd., for Sweet Peas; to Messrs. Hodsons, Ltd., for a rock garden; to Sir Jeremiah Colman, Bart., for Orchids; to Messrs. Sanders, for Orchids; to Messrs. J. Cheal and Sons, Ltd. for a garden; to Messrs. W. H. Gaze and Sons, Ltd., for a garden; to Messrs. Frank Cant, for Roses; to Messrs. Chaplin Bros., Ltd., for Roses; to Messrs. L. R. Russell, Ltd., for stove and greenhouse plants; to Messrs. Blackmore and Langdon, for Begonias; to Messrs. James Douglas, for Auriculas; to Messrs. Blackmore and Langdon, for Delphiniums; to Messrs. A. Charlton and Sons, for trees and shrubs; to the Donard Nursery Co., for shrubs and conifers; and to Mr. G. Reuthe, for shrubs.

MEDALS.

Gold Medals.—To Messrs. Clarence Elliott, Ltd., for a rock garden; to Mr. Gavin Jones, for a rock garden; to Mr. G. G. Whitelegg, for a rock garden; to Messrs. R. Bolton and Son, for Sweet Peas; to Messrs. G. Bunyard and Co., Ltd., for Irises,; to Messrs. Barr and Sons, for Tulips; to the Hon. Vicary Gibbs, for vegetables; to Messrs. H. G. Alexander, Ltd., for Orchids; to Messrs. Charlesworth and Co., Ltd., for Orchids; to Messrs. J. and A. McBean, for Orchids; to Messrs. J. Carter and Co., for Sweet Peas and other florists' flowers; to Messrs. R. Wallace and Co., Ltd., for a mixed group of Lilies, Irises, Rhododendrons and hardy plants; to Lady Aberconway, and The Hon. H. D. McLaren, for mixed group of less common plants; to Messrs. Engelmann, Ltd., for Carnations; to Messrs. Allwood Bros., for Carnations and Pinks; to Messrs. R. Wallace and Co., Ltd., for a garden; to Messrs. Sutton and Sons, for greenhouse plants; to Messrs. R. and G. Cuthbert, Ltd., for Azaleas and other shrubs; to Messrs. Hillier and Sons for Cherries, Crabs and shrubs; to Messrs. G. Jackman and Son, for Clematis; to Messrs. R. C. Notcutt, for Lilacs, Brooms and other shrubs; to Mrs. A. Sherman Hoyt, for an exhibit of Californian Desert Plants and a Californian Redwood Forest scene.

Silver-Gilt Hogg Medal.—To Messrs. Laxton Bros., for Strawberries.

Silver Hogg Medals.—To Messrs. G. Bunyard and Co., Ltd., for Apples; to Messrs. T. Rivers and Son, Ltd., for fruit trees in pots.

Silver Knightian Medal.—To Messrs. S. Bide and Sons, for Tomatos.

Silver-Gilt Flora Medals.—To Messrs. Pulham and Son, for a rock garden; to Messrs. Tuckers, Ltd., for a rock garden; to Messrs. R. and G. Cuthbert, Ltd., for Azaleas; to Mr. W. C. Slocock, for Rhododendrons; to Messrs. John Waterer, Sons and Crisp, Ltd., for Rhododendrons; to Messrs. Black and Flory, for Orchids; to Messrs. Cowan and Co., for Orchids; to Messrs. Stuart Low and Co., for Orchids; to Messrs. Gasburn and Welch, for plants and dwarf shrubs for the rock garden; to Messrs. A. and W. Perry, for a mixed group of herbaceous plants, Irises, and Lilies, etc.; to Messrs. Ben R. Cant and Sons, Ltd., for Roses; to Messrs. Alex. Dickson and Sons, Ltd., for Roses; to Messrs. En-Tout-Cas Co., Ltd., for garden; to Messrs. M. Prichard and Sons, for herbaceous plants; to Messrs. John Waterer, Sons and Crisp, Ltd., for herbaceous plants; to Messrs. W. Fromow and Sons, for Japanese Maples; to Messrs. L. R. Russell, Ltd., for trees, shrubs and climbers; to Messrs. W. Watson and Sons, Ltd., for Brooms; to the Yokohama Nursery Co., for Japanese dwarf trees and Kurume Azaleas.

Silver Flora Medals.—To Mr. W. E. T. Ingwerson, for a rock garden; to Mr. F. Street, for Rhododendrons; to the Orpington Nurseries Co., Ltd., for Irises; to Messrs. Mansell and Hatcher, for Orchids; to Messrs. Clarence Elliott, Ltd., for rock garden plants; to Mr. C. Kirch, for alpine plants; to Messrs. W. H. Rogers and Son, Ltd., for rock garden plants and dwarf shrubs; to Messrs. John Waterer, Sons and Crisp, Ltd., for rock garden plants and dwarf shrubs; to Messrs. W. Cutbush and Son, Ltd., for Roses; to Messrs. W. Easlea and Sons, for Roses; to Mr. W. Yandell, for Violas; to Messrs. Bakers, Ltd., for Astilbes; to Messrs. Carter Page and Co., Ltd., for Dahlias; to Messrs. Wilson and Agar, for hardy perennials; to Mr. T. Robinson, for Dahlias and Ageratum; to Messrs. R. Green, Ltd., for Bay trees; to Messrs. Harrods, Ltd., for clipped Box and Bay trees; to Mr. John Klinkert, for topiary

Silver-Gilt Banksian Medals.—To Mr. H. F Fletcher, for Tulips; to Mr. G. G. Whitelegg, for Azaleas; to Messrs. R. Gill and Son, for

Rhododendrons and shrubs; to Messrs. Alex. Dickson and Sons, Ltd., for Sweet Peas; to Messrs. Armstrong and Brown, for Orchids; to J. J. Joicey, Esq. (gr. Mr. J. Mackay), for Orchids (This exhibit also won the Cup offered for award for the best exhibit of Orchids shown by an amateur in a space not exceeding sixty square feet); to Col. W. Kemmis (gr. Mr. J. W. Chapman), for Primulas; to Mr. Gavin Jones, for rock garden plants; to Mr. W. Wells, jun., for rock garden plants; to Messrs. Bees, Ltd., for shrubs, herbaceous and rock garden plants; to Messrs. B. Ladhams, Ltd., for alpine and herbaceous plants; to Mr. G. Reuthe, for rock garden plants; to Messrs. Lowe and Gibson, for a group of border Carnations; to Messrs. W. Cutbush and Son, Ltd., for a garden; to Mr. Ernest Dixon, for a garden; to Messrs. W. Wood and Son, Ltd., for a garden; to Mr. Elisha J. Hicks, for Roses; to Messrs. E. Webb and Sons, Ltd., for a mixed group of Cinerarias, Schizanthus, Primulas and annuals; to Messrs. Dobbie and Co., Ltd., for Calceolarias; to Messrs. H. J. Jones, for Hydrangeas; to Messrs. A. and W. Perry, for ferns; to Mr. G. H. Dalrymple, for Lupins; to Messrs. Hewitt and Co., Ltd., for Delphiniums; to Messrs. Bakers, Ltd., for Delphiniums, Trollius and other herbaceous plants; to Messrs. M. Prichard and Sons, for herbaceous plants; to Messrs. G. Bunyard and Co., Ltd., for Paeonies; to Messrs. M. Prichard and Sons, for rock garden plants. ; to Messrs. J. Cheal and Sons, Ltd., for trees and shrubs; to Messrs. W. Cutbush and Son, Ltd., for clipped trees and Hydrangeas; to Messrs. Fletcher, Bros., Ltd., for hardy trees, shrubs and conifers; to Mr. W. J. Marchant, for trees and shrubs; to Messrs. R. Veitch and Son, for shrubs; to Messrs. John Waterer Sons and Crisp, Ltd., for trees and shrubs.

Silver Banksian Medals.—To Rev. H. Rollo Meyer, for Tulips; to Mr. W. C. Slocock, for Rhododendrons; to Mr. J. Stevenson, for Sweet Peas; to Mr. G. H. Dalrymple, for Primulas; to Messrs. Bakers, Ltd., for rock garden plants; to Messrs. Clarence Elliott, Ltd., for trough gardens; to Messrs. H. Langridge and Co., for rock garden plants; to Messrs. Maxwell and Beale, for Primulas and rock garden plants; to Messrs. W. Wood and Son, Ltd., for rock garden plants; to Messrs. Barr and Sons, for a mixed group of Irises, herbaceous and rock garden plants; to Messrs. John Peed and Son, for stove and greenhouse plants; to Mr. H. P. Russell, for Calceolarias; to Mr. H. Clarke, for Violas; to Messrs. Hewitt and Co., Ltd., for shrubs; to the Hollambys Nurseries, for trees and shrubs.

Flora Medals.—To Mr. Ernest Dickson, for a rock garden; to Messrs. H. and W. Evans, for a rock garden; to the Orpington Nurseries Co., Ltd., for a rock garden; to Messrs. R. H. Bath, Ltd., for Tulips; to E. R. Ashton, Esq. (gr. Mr. C. V. Kent), for Orchids; to Mr. S. J. Goodliffe, for a mixed group of shrubs, herbaceous and rock garden plants; to Messrs. Stuart Low and Co., for Carnations; to the Garden Services, for a garden; to Messrs. Stuart Low and Co., for Hippeastrums, Australian shrubs and other greenhouse plants; to Studley College, for Campanula calycanthema; to Messrs. E. F. Fairbairn and Sons, for Dahlias; to Messrs. Kelway and Sons, for hardy plants; to Mr. Charles Turner, for shrubs.

Banksian Medals.—To Mr. T. M. Endean, for Cacti; to Mr. H. Dixon, for Orchids; to Messrs. Daniels Bros., Ltd., for mixed group of Aquilegias, Irises, Anemones and Tulips; to Mr. G. W. Miller, for hardy plants; to Mr. C. H. Herbert, for Pinks; to Mr. James MacDonald, for grasses; to Messrs. Reamsbottom and Co., for Anemones; to Messrs. W. Wood and Son, Ltd., for herbaceous plants; to Messrs. D. Stewart and Son, for trees and shrubs; and to the Marsden Hardy Plant Nurseries, for Shrubs.

⁂ *Our remarks on the Trees and Shrubs, Roses, Hydrangeas, Formal Gardens, Educational exhibits and Horticultural Sundries, etc., will be published in our next issue.*

HOME CORRESPONDENCE.

Glossiness in Flowers.—In your issue of April 27 (p. 314), Mr. T. Wilson very kindly takes up my recent challenge (*Gard. Chron.*, March 23, p. 220), namely, to bring forward a flower with petals as glossy as those of the yellow Buttercup. He names the scarlet Oriental Poppy as a possible rival, and asks me to judge. These Poppies are not yet in bloom, so a definite pronouncement must, for the present, be withheld; but I should like to point out to anyone challenging the supremacy of the Buttercup in this respect, that in making the comparison the petal in question should be held up to the light alongside that of one of the glossy, yellow Buttercups. The lustre then, I fancy, of such a petal as that of the Oriental Poppy will appear comparatively dull, although satiny, beside the mirror-like sheen of the Buttercup. Further, it must be borne in mind that the gloss of the Buttercup petal is confined to the exposed part of the petal, *i.e.*, the distal part of the upper (ventral) surface; and is, moreover, sharply marked off from the dull basal portion. When shininess occurs in other flowers it is usually most evident at the base of the petal, gradually becoming less so distally. The nearest approach—and only a feeble one— to the Buttercup petal that I have as yet come across, is that of Saxifraga Cymbalaria. The upper part of this yellow petal is somewhat glossy and gives, with iodine, a slight starch reaction. *J. Parkin.*

FRUIT GARDEN.

NOTE ON THE APPLE BLOSSOM WEEVIL.

In spite of the cold weather during February, the Apple Blossom weevil (Anthonomus pomorum, (L.) Curt.) appears to be more common than usual this spring in many Kentish orchards. It is evident, therefore, that severe weather does not destroy this troublesome insect.

A few adult weevils were found in the Apple plantations as long ago as the first week in March. On March 9, hundreds of weevils were noticed sitting on the tops of the spiles of a Chestnut fence which surrounds an Apple orchard. This date would appear to mark the beginning of the general migration period, during which the weevils leave their winter quarters, and find their way to the Apple trees.

From the second week of March onwards the weevils have been wandering about amongst the branches of the trees, seeking shelter under loose bark and in the cracks during cold, frosty weather.

During April the weevils were more active, and pairing took place upon the trees, mainly on warm, sunny days.

Some interesting observations concerning the habits of the Apple Blossom weevil during the time elapsing between the general spring migration, and the egg-laying period of the weevil (which commences when the blossoms have reached the " cluster cup " or " pre-pink stage ") have been made.

In an average season the weevil feeds to some small extent upon the developing leaflets prior to the egg-laying season. This season, however, the weevil has been observed feeding on the leaves to a very considerable extent during the past five weeks. This may be accounted for by the fact that the egg-laying period has been delayed owing to the later blossoming of the trees.

The weevil feeds upon both surfaces of the leaves. A portion of epidermis of the leaf is removed in the first instance, and finally a small hole is bored right through the leaf. These small holes in the leaves caused by the weevils, are to be found very commonly in most plantations, and many growers consider they are the result of caterpillar attack, which, however, is not the case in a good many instances. This season the weevils have been found to feed mainly during the night, and to some extent during the late evening. Very few have been seen feeding during the day time.

Observations show that the weevils fly readily during the night, and isolated specimens have been attracted to the light of a small electric lamp.

Some varieties of Pears, mainly Conference, have been attacked by the Apple Blossom weevil this year, and " capped blossoms " are only too common in many Pear plantations in the Maidstone district.

The Apple Blossom weevil is difficult to control, since wet sprays, soil insecticides and poultry do not check it to any extent. However, large numbers of weevils may be caught in sack bands, placed around the trees in such a manner as to allow the weevils to crawl into the sacking. On standard trees the sacking should be placed from two to three feet from soil level. Where bush trees are concerned, the sacking should be tied around the trunk as near to the branches as possible.

It is important to remember that the sack bands should be in position by the first week of June, and be left unattended until November or December, when the sacking should be removed carefully and burned, or boiled if required for use again. *A. M. Massee, East Malling Research Station.*

SOCIETIES.

ROYAL GARDENERS' ORPHAN FUND.

The Annual Festival Dinner of this exceedingly useful charity was held at the Savoy Hotel, Strand, on Wednesday, May 15, under the presidency of Samuel Wallrock, Esq. There was an unusually large attendance, and those present to support the Chairman included Mrs. S. Wallrock, Lord Monkswell, Sir E. Mountain, Sir Percy C. Simmons, Mr. and Mrs. Edward Sherwood, Mr. and Mrs. George Monro, Mr. and Mrs. W. Cuthbertson, Mr. Leonard Sutton, Mr. Noe, Sutton, Mr. and Mrs. J. Cull, Mr. and Mrs. D. Ingamells, Mr. and Mrs. J. F. McLeod, Mr. and Mrs. J. M. Bridgeford, Mr. and Mrs. Howard, Mr. Peter R. Barr, Mr. and Mrs. G. Barr, Mr. A. Dawkins, Mr. and Mrs. F. Secrett, Mr. and Mrs. Jolis, Mr. J. C. Allgrove, Mr. R. B. Leech, Mr. and Mrs. C. H. Curtis, Mr. T. Pateman, Mr. and Mrs. J. B. Linford, Mr. and Mrs. A. C. Harris, Mr. Rowe, Mr. Rayner, Mr. H. Cowley, Mr. and Mrs. G. F. Tinley, Mr. and Mrs. A. Ward, Mr. and Mrs. G. Woodstock, Mr. and Mrs. R. A. Witty, Mr. and Mrs. J. F. McLeod, Mr. H. Miles, Mr. and Mrs. A. Dimmock, Mr. and Mrs. Robins, Mr. and Mrs. Hannibal and Mr. A. W. Metcalfe.

At the commencement of the proceedings the Chairman read a telegram he proposed to send to H.M. the Queen at Windsor, as Patroness of the Fund, expressing thankfulness at the recovery of H.M. the King.

Later in the evening a reply was received from Her Majesty.

In proposing " The Royal Gardeners' Orphan Fund," the Chairman said that everyone present knew what happened to a plant if it was neglected in its early days, and if the same thing happened to a child, that child would die either from neglect or disease, or be severely handicapped. He asked those present to consider what their own childhood would have been without parents to care for them when they were helpless. The orphans of to-day were citizens of the future of this great Empire, and he hoped and believed some of them would be gardeners, but 5s. a week was only equal to 1s. or 1s. 6d. before the war—about enough to buy dog biscuits—and no one had any right to see a child in want. He instanced cases of orphans cared for by the Fund, but urged that gardeners should make an effort to look after the orphans of men of their own craft. He hoped that after that night the gardeners' motto would be not " Wake up, England," but " Wake up, Gardeners." Mr. Wallrock said he had departed from what he thought was the practice of former Chairmen, and he appointed stewards to collect. He knew things were bad and money was tight—but he had never known them otherwise—and on behalf of the little children he thanked those who had so ably assisted him, and coupled with the toast the name of Mr. Edward Sherwood, the Treasurer.

Mr. Sherwood, in replying, said that the first Festival Dinner was held in 1888, and during the war when the dinners could not be held, the Fund suffered accordingly. It had been his ambition to increase the allowance to 10s. a week. He was glad to say that a step in the right direction had been made, and the Easter allowance had been increased to 7s. 6d. He read extracts from letters from guardians of orphans expressing appreciation of this increase. He also referred to the economical management of the Fund, the cost being only between £300 and £400 a year. He thanked those owners of gardens who had thrown them open for the benefit of the Fund, and those who had collecting boxes. He expressed regret at the losses the Fund had sustained by the deaths of valued helpers—Lord Lambourne, Mr. H. J. Jones and Mr. C. Dixon.

Mr. G. Monro expressed his pleasure in being selected to propose the toast of "The Visitors." There was a time, he said—a dark and dreary time—when the two gardening Charities did not have ladies at their dinners. The Committee were fishermen who, having baited their hooks with a good dinner, hoped to catch the fish of their visitors' continued interest in the Fund. Referring by name to the distinguished visitors, Lord Monkswell, Sir Percy Simmons and Sir Edward Mountain, he suggested that Sir Percy Simmons, as a member of the Bridge Committee of the L.C.C., should see that the market people were easily able to get their produce across the river to Covent Garden.

In responding to this toast, Sir Edward Mountain said he was glad that when the Chairman had made the remark that money was tight he was not proposing the toast of the visitors. Although everyone could not tell the botanical names of Orchids, everyone could love the scent of a Rose. God gave us beautiful things, and he gave us gardens, and a man who loved his garden had the right spirit in him, but whatever men had done in their gardens, they were doing a better work by looking after the orphans of gardeners.

In proposing the toast of "The Chairman," Sir Percy Simmons said that he was a man of courage, as he had shown in the way he had approached his friends for support for the Fund. He referred in glowing terms to Mr. Wallrock's garden at Stanmore, and to his growing influence in the horticultural world. When rising to reply, the Chairman had a great reception; he said no man had any right to take on a job unless he intended to do it thoroughly; he had done his best, and he hoped when the Secretary read out the list, those present would not think he had done too badly.

The Secretary, Mr. A. C. Bartlett, then announced that donations received came to the fine sum of over £1,500, and he stated that the Chairman's heroic efforts to secure the financial success of the festival had been eminently successful.

The Chairman's personal list included his own donation of one hundred guineas; Mr. W. Cuthbertson, £100; Messrs. Sutton and Sons, £50; The Marquis of Winchester, £21; Lord Riddell, Sir Edward Mountain, Bt., Sir Percy C. Simmons, Lady Catto and Messrs. Barr and Sons, £10 10s. each; Mr. W. Wells, junr., £7 7s.; Messrs Pulham and Sons and Messrs. Barr and Sons, £6 6s. each; Mrs. W. Cuthbertson, Lord Dewar, Lord Bearsted and the Knight of Kerry, £5 each. The Chairman's Stewards' lists:—Mr. Edwin Beckett, £40, including £15 15s. from the Hon. Vicary Gibbs; Mr. J. C. Allgrove, £22 6s. 6d., including £5 5s. from himself; Mr. W. H. Holloway, £17 13s. 9d; Mr. W. H. Lees, £10, including £5 from himself; Mr. Harold Tucker, £9 1s. 6d. Total of Chairman's list, £832 1s. 9d.

General List:—Messrs. Hurst and Son, £52 10s.; Messrs. Rothschild and Sons, £26 5s.; the Royal Horticultural Society, £21; Mr. W. L. Bradbury, Mr. W. T. Paulin, Mr. Noel Berridge, and Messrs. Corry and Co. £10 10s. each; Messrs. Stewart and Co. £7 7s., and Mr. R. B. Leach and Mr. E. T. Willis, £6 6s.; Mrs. May Campbell, Mrs. Ethel Shepherd, Mr. W. E. Churcher, Mr. W. Marshall, Messrs. Nutting and Sons, Mr. W. F. Read, Mr. Alfred Dawkins, Mr. Charles Heidsieck, Messrs. Waterer, Sons and Crisp, Messrs. W. Cutbush and Sons, The Southport Flower Show Committee, The Horticultural Trades Association and *The Gardeners' Chronicle*, £5 5s. each, and from *The Gardeners' Chronicle* collecting box, £5 10s. 6d.; Mrs. Edwin Tate, Lord Leverhulme, Sir Otto Beit, Bt., Mr. Gerald W. E. Loder and Mr. W. Mitchell, £5 each.

The Fund's Stewards:—Mr. J. M. Bridgeford, £78 5s., including The Associated Seed Growers, Inc., U.S.A., $50; Messrs. J. Bodger and Sons, £5 5s.; Messrs. Watkins and Simpson, £5 5s.; Mr. Alfred Watkins, £5 5s.; Mr. J. M. Bridgeford, £5 5s.; and Mr. A. H. Howard, £5 5s. Mr. J. F. McLeod, £30, including £5 from Mr. D. B. Crane; Mr. J. E. Dixon, £25; Mr. F. Moon, £21, including £5 5s from Sir James Caird; Mr. A. W. Metcalfe, £13 13s; and Mr. A. Rayner, £12 12s.

Covent Garden List, per Mr. D. Ingamells.—Mr. George Monro, C.B.E., £21; Mr. F. A. Secrett, £21; Mr. J. Poupart, Mr. David Ingamells, Mr. Harry Miles, Mr. J. L. Kinnell, Mr. John Cull, Mr. M. Larsen, and Mr. A. C. Harris, £10 10s. each; Mr. H. F. Hannibal and Mr. Raymond Rochford, £7 7s. each; Mr. R. T. Bates, £6 6s.; Mr. John Firmin, Mr. A. Dimmock, Mr. Walter Turner, Messrs. W. T. Ware, Ltd., Mr. John Kirk, Mr. John B. Linford, Mr. R. A. Witty, Mr. A. H. Stevens, Mr. W. Maxwell, Mr. A. H. Maxwell, Mr. Frank Ladds, Mr. H. J. Edwards, Mr. Alfred Ward, Messrs. Charlesworth and Co., Mr. A. Robins, Mr. A. Staddon, Mr. H. O. Larsen, Mr. Frank Ridley and Mr. A. Bainbridge, £5 5s. each.

A capital programme was arranged by Mr. Ralph Norris; the tables were pleasingly decorated chiefly with Roselandia Roses and yellow Arums; the dinner was excellent, and the speeches short. The toast of the Secretary, Mr. A. C. Bartlett, given with musical honours and proposed by Mr. Nicholls, was followed by Auld Lang Syne and the National Anthem.

Obituary.

John Collins.—The death occurred on Sunday, May 5, of Mr. John Collins, who for forty-seven years was gardener to the late Sir Mark Oldroyd, at Hyrstlands, Dewsbury. Mr. Collins, who retired in July, 1927, was a highly respected man in the district, being a member of the old Dewsbury Borough Liberal Association, and a member of Batley Liberal Club.

Albert Harding.—On Saturday, May 4, Mr. Albert Harding, of Nab Lane, Mirfield, gardener to Mr. J. Barraclough, Bank House, passed away after an illness from which he had suffered a considerable time. He was a familiar figure in Mirfield where he was held in great respect.

ANSWERS TO CORRESPONDENTS.

CANTALOUPE MELONS.—*E. H. M.* Cantaloupe Melons may be grown in unheated frames without a hot-bed, and are then of superior flavour to imported fruits. Frame Melons cannot be produced in less than fifteen weeks from seed-sowing to the ripe fruit; now is a good time to commence, as the heat and light so essential to success are gradually on the increase. The compost most suitable is a loam of somewhat heavy nature with a little old lime-rubble or charcoal added; rich, light soil will enable the plants to fill a frame with rampant growth, but this growth will not finish the fruits. Sow the seeds in small pots or direct on the mounds of soil in the frames. Although Melons appreciate water and moisture when growing, they should be planted about two inches higher than the level of the surrounding compost. Two plants to a light are sufficient, and three breaks from each plant will be ample; when the shoots nearly touch the sides of the frame remove the growing points, as this will induce the laterals to produce flowers and fruits, and when about the size of Walnuts, six to eight fruits to a light, and of uniform size, should be selected for the crop, and the remainder removed. Stop the growths at the first joint beyond the fruit, and also those from which surplus Melons have been removed. By this means, and by constantly pinching the fresh laterals, the premier leaves will have plenty of room to develop and still allow sun and air to reach the surface of the bed. Raise the fruits on inverted pots; top-dress the roots with fresh compost and bone-meal; ventilate the frame carefully on bright days; syringe the plants early in the day when the frame is hot; and feed with warm liquid manure twice a week while the fruits are swelling. When the fruits have attained full size and are approaching ripeness, feeding must be discontinued, and clear water only given in diminished quantities, with less syringing and more air until the fruits are ripe.

NAMES OF PLANTS.—*A. E. W.* 1, Rhododendron Manglesii; 2, R. Halopianum, both hybrids of R. Aucklandii.—*H. W. H.* Symphytum tuberosum.

STOCKS SUFFERING FROM FOOT-ROT.—*A. B. H.* The Stocks are attacked by a species of Phytophthora, which causes foot-rot in many plants. The spread of the fungus in the seed-boxes may be prevented by watering the seedlings with Cheshunt Compound. It is unlikely that the same fungus is attacking the Brassica seedlings. They are probably infected with the damping-off fungus, due to Pythium debaryanum. Infection of cultivated plants may arise by the use of virgin soil in which Cruciferous plants were growing. Infected soil should be steam-sterilised (180°F. for three hours) before it is used for seed-sowing.

TULIP DISEASE.—*J. W.* Naphthalene would not be injurious to summer bedding stuff at the rate of two ounces to the square yard if dug in to a depth of six inches, so that the fumes would rise and kill the millipedes in the soil, including the snake millipedes which are often very destructive to the roots and tubers of many plants, especially the millipede named Blanjulus pulchellus. To get rid of the fungus, Botrytis Tulipae, it would be desirable to remove nine to twelve inches of the top soil of the bed, shovelling up all the loose soil loosened by the spade, in order to get rid of the sclerotia of the fungus that may be on pieces of decayed bulbs or even in the soil. The old soil should be buried where it would not be disturbed for some years. That could very well be done now, and two to three ounces to the square yard of naphthalene dug six inches into the soil in autumn, about a fortnight before planting the bulbs, so that fumes would be rising to protect the bulbs from millipedes. Old garden soils containing much humus, are liable to be infested with both the above enemies.

VINE LEAVES UNHEALTHY.—*T. B. S.* The leaves sent for examination were very thin and small for basal leaves, and were so dried up that it was impossible to diagnose the trouble accurately. Without more information in regard to the compost, construction of the border, and as to whether you grow any other plants in your vinery, it is impossible to arrive at a correct conclusion of the injury, It rather points to thrips, which may be introduced by other plants, or it may be any of the various diseases that vines are subject to. Pay careful attention to ventilation and atmospheric conditions, and dust the leaves with dry flowers of sulphur which cannot injure the vines and may easily improve their condition.

Cereal Symbiosis.

IT is long since the even tenour of the way of botanical research has been so brusquely disturbed as it is by the pronouncement that our cereals provide the staff of life, not by their unaided efforts but by collaboration with certain fungi. This, in fact, is the assertion made by Messrs. Jodidi and Peklo.[*] The assertion is one which, in spite of its surprising nature, cannot be dismissed because of its lack of verisimilitude. The views put forward by the authors are, briefly, as follows:—The aleurone grain layer of cereals—a layer rich in proteins which occurs just beneath the husk of Wheat or other cereal grains—contains certain glutens which are peculiar to cereals and other grasses. They are not found in other plants. Gluten is a complex protein peculiar to cereals. It occurs in the aleurone grain layer and other parts of the endosperm of Wheat, etc., and one of its constituent proteins is known as "prolamin," which possesses the property, unusual in proteins, of dissolving readily in alcohol. It has, of course, been supposed, hitherto, that this aleurone grain layer which constitutes a store house of proteins, is produced, like other parts of the grain, by the unaided efforts of the Wheat plant. It has, however, been known for a long time that fungal hyphae occur in the tissues of certain grasses as, for example, English Rye Grass (Lolium perenne), with at least as much frequency as fleas in the coat of a dog, and it has often been suggested that fungi, of which these hyphae are parts, are always associated with this grass; are, in fact, symbiotic. It has even been suggested that, like the bacteria in the nodule of Leguminous plants, the symbiotic fungus of Rye Grass possesses the power of fixing nitrogen. Mr. Peklo, who has made a close study of these hyphae, has succeeded in isolating them from the grains of Rye Grass and in cultivating the fungus in the laboratory. From its detailed appearance Mr. Peklo comes to the conclusion that it is a member of the fungus family of Smuts, some of which live parasitically upon cereals and work much destruction. Similar fungi appear to exist also in the grains of Wheat and other cereals. The authors claim, indeed, to have seen the hyphae of these fungi penetrating the aleurone grain layer and suggest that it is the fungus and not the grass plant, which produces the aleurone grains. If this, indeed, be so, mankind will have to transfer its acknowledgment of indebtedness for its daily bread from the Wheat plant to the fungus, or rather, will have to divide his gratitude between the two partners of this symbiosis. In confirmation of their remarkable conclusions, Messrs. Jodidi and Peklo claim to have shown that the fungus isolated from the Rye Grass grain and grown in artificial media, actually makes the same protein—prolamin—as occurs in the gluten of the Wheat grain. This evidence seems well-nigh conclusive, but, needless to say, when facts so subversive of current ideas are put forward, even although they are apparently well attested, credence remains coy, preferring to await the independent confirmation of the strange news, rather than to accept unhesitatingly the new discovery. We may state, however, in the meantime, that the conclusions reached by Messrs. Jodidi and Peklo, if proved to be well-founded, will rank among the most important of recent years. Symbiosis which we knew already to be capable of so much, would then seem to be like Habakkuk, *capable de tout*, and Ceres will cease to be a goddess in her own right, and single, but mated with an hitherto unknown deity, Myxomycetes, and owing her power to that union!

Bluebell and Chestnut Sunday.—Sunday, May 26, was Bluebell Sunday at Kew and Chestnut Sunday at Bushey Park. Had also the Laburnums, Lilacs, Thorns or Wistarias a Sunday in their honour, a journey to Kew on the same day to see either of the families named would have been worth while, for each and all were a feast of colour. Between twenty-six and twenty-seven thousand people passed through the turnstiles at Kew, large numbers bringing lunch and tea baskets for a picnic in the grass or woodland. Although producing glorious sheets of colouring beneath the trees in the Queen's Cottage Grounds and elsewhere in the woods, the Bluebells at Kew are not so vigorous this year as usual. In common with most of the vegetation at Kew, they are feeling the effects of a shortage of rain.

May-flowering Tulips at Kew.—One of the numerous floral treats in store for visitors to Kew during the Chelsea Show was a display of May-flowering Tulips in the series of flower beds between the Palm House and pond. Somewhere in the neighbourhood of ten thousand bulbs, timed to flower at one time, gave a feast of colour of great beauty. Various spring flowers are planted as a groundwork for the bulbs, these including Wallflowers, Violas and Aubrietias. They, however, play but a small part in the effect as a whole, which is dominated by the brilliant, massed colours of the Tulips. The best of the Darwin Tulips include Clara Butt, delicate blush-rose; Loveliness, bright rose; Le Notre, rosy-pink; Psyche, delicate rose-pink; Madame Krelage, deep rose; Suzon, soft rose; and La Candeur (White Queen). Conspicuous among the May-flowering Cottage Tulips are Inglescombe Yellow; vitellina, primrose-yellow; Golden Bronze, Panorama, madder-red, tipped golden-bronze; Medea, carmine, shaded salmon; and St. James, reddish-mahogany. The four last-named are very effective Breeder Tulips for bedding.

Honour for Mrs. Sherman Hoyt.—The Council has awarded Mrs. Sherman Hoyt an Honorary Life Fellowship of the Royal Horticultural Society and, we understand, will award her special "Congratulations," in addition to the Gold Medal she received for her exhibit of Californian plants at Chelsea Show.

Harding Silver Cup for Paeonies.—The fourth of a series of cups presented by Mrs. Edward Harding is offered for award in 1929 for the best exhibit of three flowers of each of six varieties of Paeonies shown by an amateur. Banksian Medals in silver-gilt and silver are offered by the R.H.S. as second and third prizes. The competition will take place at the fortnightly show at the Society's new hall, in Greycoat Street, on June 25, and all exhibits must be ready for judging by 11 a.m. that day. Entries for the competition must be made on forms obtainable from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1, by whom the completed forms must be received not later than by the first post on Tuesday, June 18.

Captain F. Kingdon Ward.—We regret to announce that Captain F. Kingdon Ward, now in the Far East, is ill, at a place named Moung. Beyond the fact of his illness, no news has been received for several days. We trust that "no news is good news," and our readers will join us in sympathy with Mrs. Kingdon Ward, and in hopes for the speedy recovery of her intrepid husband.

A Novel Afforestation Proposition.—Mr. W. P. Templeton, a Parliamentary candidate in Banffshire, sets forward a rather novel proposal in the form of a scheme for planting trees on rough agricultural land. On farms there are three kinds of land—arable and pasture, and rough ground which is not good for cultivation or pasture. He believed it would be possible for the Government to grant some subsidy to the farmers for the purpose of planting trees on rough land—seventy-five per cent. of the cost of the trees—which would be the property of the tenant and the farm, and would be saleable to his successors according to growth. He had brought his suggestion before the Scottish Office, and he believed it would not be difficult to persuade whatever Government may be in power to see the benefit of such a scheme in the north-east of Scotland. He felt the proposal would be of more advantage than the big afforestation schemes, good as they are, and he intended to go fully into the matter. From enquiries he had learned that after a period of ten years the trees did not require anything like careful attention. The work could be done by the farmers at times when they were not engaged in other work. The result would be a national asset and an economic use of rough land.

"Hardy and Half-hardy Plants."—Under this title Mr. A. W. Darnell, Hampton Wick, Middlesex, has commenced the publication of a monthly magazine for amateur and professional gardeners. Judged by its first issue, this is a delightful production, and one that differs in style from the average horticultural weeklies. It is a kind of horticultural *Bot. Mag.*, but of demy quarto size, which enables the editor to display life-size reproductions of very many plants. The new work aims at giving illustrations and descriptions of beautiful and interesting plants suitable for outdoor culture in the British Isles. Each issue is to contain not fewer than twenty-one life-size reproductions, one being in colour. Lithography is the process used, and is applied to the letterpress as well as the illustrations. No similar work has been attempted. We heartily congratulate Mr. Darnell upon the success of his first issue, and trust that he will receive sufficient support to enable him to continue. All the reproductions are from his own brush and pen and contain a detailed accuracy that is very pleasing. Mr. Darnell is known to our readers, as many of his plant drawings have been reproduced in these pages, and he is responsible for the horticultural monograph of "The Genus Primula," now appearing. The only criticism we have to offer is that a summary of the history of each plant would add to the interest of *Hardy and Half-hardy Plants* and make it more valuable as a work of reference. The price is 2s. 6d. monthly, thus for 30s. a subscriber would in one year procure an album of first-rate illustrations of no fewer than 250 hardy and half-hardy garden plants.

---

[*] "Symbiotic Fungi of Cereal Seeds and their Relation to Cereal Proteins," by S. L. Jodidi and Jaroslav Peklo. *Journ. of Agric. Research*, Vol. 38, No. 2. Washington, D.C. January 15, 1929.

Vegetation of the Great Barrier Reef.—Mr. G. Tandy, who, with Mr. F. S. Russell, conducted an expedition to Low Islands, gave a preliminary account, illustrated with lantern slides, of the vegetation of the Great Barrier Reef, at a recent meeting of the Linnean Society. He stated that Low Islands present a very interesting set of problems for the botanist. As one comes from the southward they are the first of the "low and wooded" islands of the early navigators to be encountered. The arrangement of a Mangrove swamp to windward (with Rhizophora mucronata the dominant) and a more or less vegetated cay of coral sand to leeward, is found in considerable numbers northwards from here. To understand the formation, the behaviour of the South-east trade wind (pretty constant here from April to November) must be considered. In early morning it will be at S.S.E. and light, but as the day goes on it will shift to E.S.E. or even E. and freshen. This means that the heaviest seas will commonly be on the north side of the Mangrove island. Here the drift of the coral shingle is driving the Mangrove back. On the lee side of the swamp, however, they are extending in a westerly direction. The Vice-President congratulated Messrs. Russell and Tandy on the results of their labours and on the very interesting story of the expedition. Dr. A. B. Rendle, expressed his congratulations on the successful results of the expedition, and as a botanist referred more particularly to the botanical results. He mentioned that, although the botanical department of the British Museum had to suffer the loss of Mr. Tandy's services, while he was absent with the expedition, the rich material he had brought back would be of great value in elucidating the symbiotic relations of life on a coral reef.

Legacies to Gardeners.—The late Mr. Jenneson Taylor, of Brookside, Sunderland, who died on March 24, left £100 to his gardener, Mr. A. Brown, if in his service at the time of his death.—The late Miss Clara Tilbury Tarner, of St. John's Lodge, Tilbury Place, Brighton, who died on February 1, left £100 to her head gardener, Mr. David Turner, and her late gardener, Mr. Robert Hillier, and £200 to her gardener, Mr. Charles Poughton.—The late Mrs. Alice Ann Dalton, of Park House, Catham Park, Bristol, who died on March 4, left £300 each to her gardeners, Mr. Robert H. Jennings and Mr. James H. Sayers.—The late Mr. Hugh Hathorn Nicholson, of Spital Hall, Spital, Cheshire, who died on February 7, left £100 to his gardener, Mr. George Hancock, if still in his service.

Nice Horticultural Exhibition.—A successful exhibition, organised by the local horticultural Society, took place at Nice from March 30 to April 3, and at the same place and time the tenth Congress of the French National Horticultural Federation was held, under the Presidency of M. Alfred Nomblot. The exhibition was excellently arranged by M. Giuglaris, head of the parks department at Nice, who is also the Secretary of the Society. The jury had for its president the Comte de Kerchove de Denterghem, Governor of East Flanders, and President of the Ghent Royal Botanical and Horticultural Society. The Premier Grand Prix d'Honneur, offered by the President of the Republic, was awarded to the firm of Flandria, at Bruges; and a second Premier Grand Prix, offered by the Prince of Monaco, was won by M. Dental, with the produce of his nurseries at Golf Juan. The Nice Municipality's special prize was awarded to Messrs. Vilmorin-Andrieux, of Paris, and that of the Council of the Alpes-Maritime to MM. Maiffret frères, Beaulieu-sur-Mer. The judges were amazed at the quality and variety of the exhibits, considering the unprecedented cold of the winter and spring, and were greatly interested in the many beautiful public and private gardens which were visited at the close of the exhibition and congress.

Mr. C. H. Cooper. — Recently appointed chief assistant to Mr. J. Roberts, the Superintendent of the Public Parks and Cemeteries at Chesterfield, Mr. C. H. Cooper is already well-known as a capable gardener and successful exhibitor. In his early years he served under Mr. Nash and Mr. Pearce at Badminton, and then passed on to the gardens at Clonna, Sydney, Gloucestershire. Two-and-a-half years later Mr. Cooper went to Bignell Park, and eventually gained experience at Maer Hall, Staffordshire and at Swinfen Hall, in the same county. Later, he became indoor foreman at Polesden Lacey, Surrey, and then general foreman at Blyth Hall, Nottingham, where a year later he became gardener and remained in that position until the death of his employer. Desiring to engage in public gardening, he obtained his present position at Chesterfield. While at Blyth Hall, Mr. Cooper proved a most successful cultivator and exhibitor of Chrysanthemums, fruits and vegetables, his successes including a sixteen-guinea challenge cup for Chrysanthemums, two silver cups won outright after winning them in three consecutive years, two gold medals, the George Bunyard Silver Medal, and forty-nine first, fourteen second, and eleven third prizes.

MR. C. H. COOPER.

Tree-felling Competition.—The Executive of the Northern Branch of the Royal Scottish Arboricultural Society, whose headquarters are in Inverness, is to be congratulated on the fine success that has attended its inauguration of a tree-felling competition—the first of its kind in the north—which took place at Dalcross, on the Earl of Moray's estate, some ten miles from Inverness, on Saturday, May 18. Superb weather prevailed, the material provided for the competitors was of the best, and intense interest was taken in the day's proceedings. Eighteen teams entered from eight counties, and great enthusiasm was evinced. A large gathering watched the proceedings, including Colonel Neil Fraser-Tytler of Aldourie, the President of the Branch. The conditions were that each team, consisting of two competitors, had to fell and trim two trees—a Larch and a Spruce—and marks were given them for setting in, cutting low, axemanship, throwing the tree between pegs set twelve feet apart, the cleanest break, freedom from injury to the timber, and for trimming and snedding. The competition proved a highly practical and successful demonstration in forestry work, and, as Colonel Fraser-Tytler said at the close, the competitors showed remarkable skill and aptitude in their work. Mrs. Rose, of Kilravock, presented the prizes to the winners as follows :—(1) £5, J. Lyons and J. Davison, Dumdreggan Sawmills, Invermoriston; (2) £3, Finlay MacKay and Alexander Finlayson, Brahan Estate, Conon Bridge; (3) £2, A. Grewar and R. Coutts, St. Clair, Dores. Messrs. Colin Moir and J. Tough, Strathconon, won the prize for the best-kept tools. Those well-known foresters, whose names are household words in forestry circles in the north, Messrs. Gilbert Brown, Feaks, R. Anderson and John Clark, were the judges, while Mr. Alexander Ross, Forres, judged the tools. The whole formed a capital display, and Major David Ross, Inverness, the Secretary of the Branch, deserves hearty congratulations upon the very complete arrangements he made for the contest.

Memorials to Sir William Schlich.—On Thursday, May 23, honour was done to the memory of the late Sir William Schlich, Inspector-General of Forests to the Government of India, and afterwards Professor of Forestry as Oxford University, when Dr. F. W. Pember, the Vice-Chancellor, unveiled a bronze portrait plaque memorial to him at the Oxford School of Forestry, an institution which Sir W. Schlich was instrumental in founding. A second memorial to him will also be established, the Forestry Commissioners having agreed to the proposal of the Memorial Fund Committee that the area of forest, to be named the Schlich Forest and situated, if possible, within easy reach of Oxford, be made available for experimental work. In this forest a group of Oak trees will be planted and maintained in Sir William's memory. Sir W. Schlich was one of the leading authorities on silviculture, and it was through his endeavours that a Chair of Forestry was inaugurated at Oxford University. His *Manual of Forestry* is well-known as a standard treatise.

Wintry Spring in the Arnold Arboretum.—The *Bulletin* of the Arnold Arboretum, dated April 27, states that "the atrocious weather of the past two weeks had a disastrous effect on plants that happened to be in full blossom. Plants may be very hardy, but it is not to be expected that their tender blossoms can withstand snow, sleet, hail, several degrees of frost, and high winds. Often as not the first flowers of spring suffer for their daring, but this year they have been punished most severely. When the first *Bulletin* went to press two weeks ago the group of Rhododendron dauricum mucronulatum on Bussey Hill was a wealth of rosy-purple, thousands of blossoms being fully open; the Star Magnolias in front of the Administration Building were sheeted in white, and the Manchurian Apricot was in full bloom. Before the *Bulletin* appeared in type every expanded blossom had been destroyed. Not before have the flowers of R. dauricum mucronulatum suffered so severely as this year; every open or partially open flower was absolutely ruined. The Magnolia blossoms were browned and resembled sodden, brown tissue paper, and the flowers of the Manchurian Apricot were killed. The Forsythias, whose blossoms are accustomed to a good deal of buffeting each spring, have suffered far more than is usual, and their lustre and beauty has gone from them, although late expanded buds are now doing their best to enliven the branches. Fortunately, only a few subjects had burst into bloom, otherwise the tale of woe would have been even sadder. The return to cold, boisterous and stormy weather has had a retarding influence on all vegetation. It has also greatly hindered spring work; much of the land in the Arboretum lies low, and this has been flooded, making it impossible to do any transplanting or even to cultivate the ground. The probability is that this stormy spell will be followed by hot weather, which means that the spring season will be unusually short. The unseemly weather has had the curious effect of advancing the blossoming period of some plants while retarding that of the majority. For example, on Bussey Hill a Pear tree (Pyrus ussuriensis) is in full blossom, preceding, instead of its usual practice of succeeding, the earliest flowering Cherry. In the Arboretum the first blossoms are just opening on the Sargent Cherry; at North Easton, which in spring is usually a week behind us, this Cherry is in full bloom and, so too, is it across the Parkway from the Arboretum. While the Cherry blossoms have remained virtually at a standstill during the past two weeks, the buds on the Lilac bushes have grown considerably, and there is great promise of a fine crop of flowers. After a careful survey it is comforting to note that although the first flowers of spring have had a rude awakening and suffered heavily for their haste, no material damage has been done to those which had not progressed beyond the bud stage. If from now on normally decent weather prevails, there will yet be a rich harvest of spring flowers."

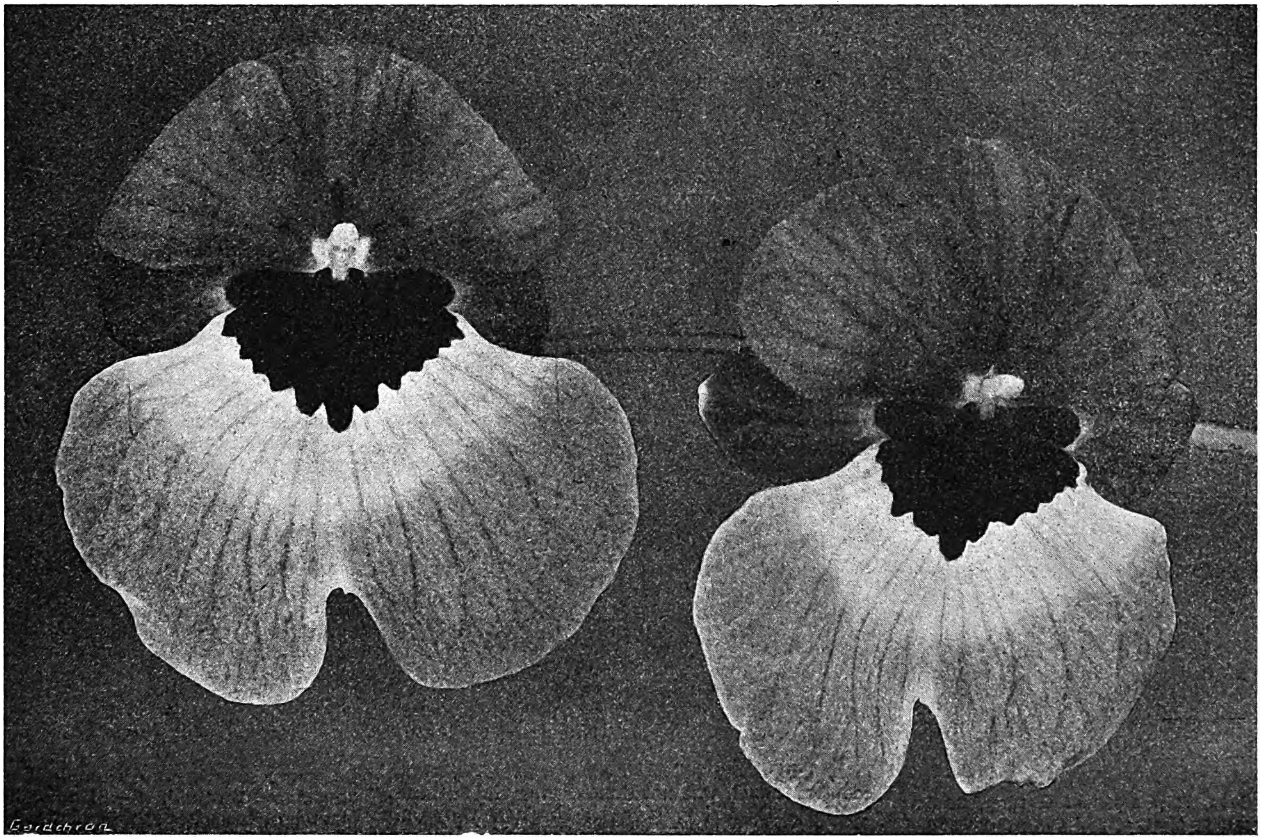

FIG. 200.—MILTONIA T. B. ARMSTRONG.

R.H.S. First Class Certificate, Chelsea Show, May 22. Flowers, red, rose, white and black. Shown by Messrs. Armstrong and Brown.

(see p. 383.)

Hightown Common.—We learn that Hightown Common, a beautiful tract of heathland some forty acres in extent, adjoining the New Forrest and situated near Ringwood, is to be acquired for the Nation and vested in the National Trust. It is proposed to erect on the land a memorial to the late Lord Eversley, who was instrumental in securing this lovely area for the public.

The Royal Society's Conversazione.—Exhibits of a highly scientific nature, and covering a wide field, were displayed at the conversazione held by the Royal Society at its headquarters at Burlington House, on May 15. There were two exhibits of interest to horticulturists. Miss D. M. Cayley, of the John Innes Horticultural Institute, had a series of specimens demonstrating the transmission, by bulb grafting, of the virus responsible for "breaking" in Tulips, while the Rothamsted Experimental Station staged an interesting exhibit of plants toxic to animals and fish; these included several tropical Leguminous plants, such as Derris and Tephrosia, extracts of the toxic principles being displayed in several instances. The exhibit also included English-grown Pyrethrum (Chrysanthemum cinerariaefolium), and the products yielded by it.

Chiswick House Estate.—On Thursday, July 4, Prince George will open the grounds of Chiswick House, some sixty-six acres in extent, to the public. The grounds, together with the historic house, were purchased from the Duke of Devonshire by public subscription, and are now under the care of the Brentford and Chiswick Urban District Council. We were privileged to see the grounds during the present week, when the Wistarias on the walls and along the front of the famous Camellia house were wonderfully beautiful, while Rhododendrons, Horse Chestnuts, Hawthorns and Lilacs added their quota of beauty and fragrance to this fine old-world garden, where the trees in general and the Lime Avenue and the Cedars in particular, are particularly good.

Forest Development at Thetford.—What will, it is stated, be the largest forest in England, is rapidly materialising in the vicinity of Thetford under the auspices of the Forestry Commission. Some 15,999 acres of what was once barren, waste land have already been planted with Pines, Larches and Fir trees, and it is estimated that the forest, when completed, will stretch for sixteen miles over Norfolk and Suffolk, and will provide some of the best timber in the country, the land being specially suitable for the growing of Coniferous trees.

Appointments for the Ensuing Week.—Monday, June 3: Harrogate and District Horticultural Association's meeting. Tuesday, June 4: Royal Caledonian Horticultural Society's meeting; Three Counties Agricultural Show at Gloucester (three days). Wednesday, June 5: National Carnation and Picotee Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. Thursday, June 6: Iris Society's Show (two days); Bideford and District Horticultural Society's meeting. Friday, June 7: Manchester and North of England Orchid Society's Annual Meeting. Saturday, June 8: Derbyshire Horticultural Association's meeting; Leeds Paxton Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Emigration.*—We are not anxious to give advice to emigrants, although continually solicited to do so. A man's temperament, means, habits and peculiarities exercise so great an influence upon his destiny, that it requires a considerable acquaintance with him for even the most sagacious friend to know where in the wide world he is more likely to be successful than at home. It will, therefore, be easily understood why we shrink from the responsibility of saying that which may determine, whether for good or for evil, the future destiny of any correspondent. Nor is it easy to know what value to attach to the reports which reach Europe concerning distant colonies. That statements are very often over-coloured—unintentionally, perhaps—is certain. Nor can it well be otherwise; for if it is natural for a man to eulogise the country in which he has created his fortune, it is equally his interest to say whatever will attract thither the population which will increase the value of his property. And, on the other hand, he who fails assigns his want of success to anything rather than his own unskilfulness, imprudence, or lethargy. The one exaggerates what is good, and overlooks the reverse; the other exaggerates what is evil and forgets the unquestionable good. *Gard. Chron., June* 3, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Coelogynes.—Many species of this genus which require warm growing conditions, such as C. Dayana, C. Lawrenceana, C. Sanderiana, C. pandurata and others, are now producing flower scapes simultaneously with the new growths, and will require an increased supply of water at the roots each time the compost appears dry, to prevent the pseudo-bulbs shrivelling. Those that have pendent flower spikes—C. Dayana and C. Massangeana—should be grown suspended from the roof, so that their flowers may be seen to the best advantage. A moist and buoyant atmosphere should be maintained and shade provided from strong sunshine, every encouragement being given to assist the development of good flowers. The plants should not remain dry at the roots for long periods, and the flowers will remain in perfect condition for a long time if, when they commence to expand, the plants are given cooler and drier quarters. When flowering is finished, any necessary repotting may be done, using well-drained receptacles and a compost of three parts Osmunda fibre and one part Sphagnum-moss, with a little fibrous loam for the strong rooting kinds, adding crushed crocks to keep it porous. Some of the scandant growers, like C. Meyeriana, are best grown on a block or a Teak-wood raft. Careful watering is necessary until the roots are well established; the surroundings should be kept moist, but moisture should not be allowed to collect in the new growths or decay will set in. Coelogyne cristata and its varieties, that have passed out of flower and are growing freely, should receive attention at the roots. Unless the plants are deteriorating or are overgrown, top-dressing will be sufficient, just removing all decayed bulbs and sour compost, and then working in the fresh compost around the roots; secure any loose leads in position with wire pegs, and syringe the plants occasionally in suitable weather. These Orchids will thrive in an intermediate temperature, allowing more light and air as the pseudo-bulbs develop.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Peaches and Nectarines.—These have set a plentiful crop of fruits, and a good season is anticipated. Very few curled or blistered leaves have been noticed, although the nights during April, while the trees were in blossom, were very cold. It will now be safe to remove protective material from the trees and to remove at intervals, or stop, superfluous shoots. All the badly placed and small fruits should also be removed, three or four of the best placed being retained on each branch. Finally, these should be reduced to one when the trees have passed through the stoning period. When reducing these fruits, and when feeding, the vigour of each tree must have due consideration. Those that are inclined to make gross growths should be allowed to carry more fruits than weakly ones; and food, which should be withheld from the strong, should be judiciously applied to those that are not so vigorous. Give the trees and borders a thorough drenching with water, with a hose, to promote clean, healthy growth, and assist in keeping red spider in check. Afford frequent applications of liquid horse- or cow-manure, and apply a mulching of half-decayed manure, to keep the soil moist and cool, to the outward stretch of the roots. The applications of liquid manure may be continued until the fruits show indications of ripening, after which clear water only should be given.

Protecting Fruits from Birds.—Preparations should now be made to protect the Strawberry crop with netting against birds. Do not wait for the fruits to show colour, but place the nets in position at once. The most convenient method of protecting these fruits is to have a boundary of wire-netting, one-inch mesh, supported by strong six-feet stakes, driven well into the ground, and from the tops of these, strands of single wire stretched from side to side and from top to bottom, forming a rough meshwork to support the ordinary fish-netting. This method requires less netting, makes the crop more secure from birds and vermin, and enables the gathering of the crop to be accomplished more easily. Mice are sometimes very troublesome, especially in gardens where the walks are edged with Box. The earliest opportunity should be taken to poison these pests before the fruits commence to ripen, for after that, poison in any form should not be used. If, however, they continue to give trouble, recourse should be had to the "break-back" type of trap.

Raspberries.—The same protective measures must be taken for these fruits as for Strawberries, but there is no need yet to have the nets placed in position. Water is very necessary for both crops, but particularly so for the Raspberry. The season continues to be very dry and the soil is lacking moisture to a great degree. Every endeavour should be made to give this crop one or two good soakings of clear water, to be followed by applications of well diluted liquid manure. Where there is a surplus of suckers between the rows, these should be thinned, by pulling them out rather than by cutting them off at the soil level. Lawn-mowings spread, not too thickly, on both sides of the rows will help to conserve moisture and prevent the germination of annual weeds.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Summer Bedding.—All plants for summer bedding should be thoroughly hardened off preparatory to being planted in their flowering quarters. Many plants receive a severe check at this stage as a result of sudden exposure to outside conditions; therefore, see that all are hardened off gradually, even if, as a result, planting has to be delayed a few days. Where beds have been filled with spring-flowering plants, these should be cleared and dug so soon as the occupants are past their best. It is advisable to enrich the soil by applying well-decayed manure or decomposed vegetable matter, if such was not done during the autumn. If the soil is dry, give the beds a thorough soaking of water a day or two before planting. By this date it will be safe to plant the majority of bedding plants in their flowering quarters; but, with the more tender kinds, such as Begonias, Heliotrope, Petunias and Salvias, it is advisable to defer planting for a week or so in some districts, in case ground frosts occur. So far as practicable, take advantage of dull, showery weather for planting subjects from boxes or frames; those grown in pots may be transplanted without undue disturbance of their roots at any time; if dry at the roots, give a good watering. Plant them firmly, and when the soil is moderately dry, hoe the beds to create a loose surface, which will act as a mulch and prevent evaporation of moisture. Continual watering is not to be recommended, but during hot, dry weather a light spraying overhead during the evening will be beneficial and assist the plants to become established. Where large beds have to be furnished, Pentstemons and Antirrhinums give satisfactory results. Of the former, the varieties known as Castle Forbes and Lady Mary Hope are among the best of the scarlet sorts; both are good growers and very free-flowering, especially the former. Day Dream is probably the best pink Pentstemon for the purpose. These require liberal treatment in the way of manure and close attention to watering; if dry conditions prevail for any length of time it will be found beneficial to apply a mulch of well-decayed manure over the surface of the bed. For large borders or beds on sloping banks, the tall forms of Antirrhinums are effective; for the medium or small-sized beds, the intermediate sorts are most useful, while for carpeting Rose beds, the dwarf section is admirable. Where intermediate Antirrhinums are used, it is a good plan, especially if the bed is of large dimensions, to employ Gladioli of a different colour as dot plants; these, if started in five-inch pots as previously advised, will be in good condition for planting by early June. Large beds of Pentstemons are also better if interplanted with Gladioli, provided they are of suitable colour shades.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Vines.—The cold nights and sudden bursts of hot sunshine during the day make it extremely difficult to maintain steady conditions. Early Grapes will now be colouring and possibly causing some anxiety as to "finishing"; some relief may be obtained from careful surface feeding, together with a slightly lower temperature, with a little extra air at night. As the Grapes approach ripeness they will require cooler conditions with liberal ventilation and less moisture, but, with the whole of the summer yet to come, the floors and walls must still be well damped and syringed once or twice a day when the weather is favourable, to admit of a free circulation of fresh air. Red spider, too, often puts in an unwelcome appearance at this stage, and demands immediate attention; if solitary leaves are attacked they may be sponged at once with soapy water, as sulphur cannot be employed conveniently at this stage. The midseason varieties in succession houses are now swelling their fruits freely and should receive liberal supplies of warm, diluted liquid manure applied to the inside borders and sprinkled over the paths and surface of the beds so soon as the sun leaves the roof on fine evenings. Night air should be given about 8 p.m., and shut off early next morning, when damping will precede airing for the day; the maximum day temperature of 80° to 85° should always be approached gradually by slight additions of air while the temperature is on the rise, and, similarly, reducing must be carefully followed on converse lines. As Grapes swell most when early afternoon closing is practised, the house should be closed in time for the temperature to reach 90°, with plenty of atmospheric moisture. As a little steady artificial heat is necessary, fires should be started in time to let the temperature fall gradually to 70° at 9 p.m., and to 65° the following morning. Although thinning may be considered finished, it will be well to look over large bunches after stoning is finished, especially of Gros Colmar, which is very deceptive. Pinch back the strongest laterals and regulate the foliage to maintain a free circulation of air between it and the glass; weak lateral growths need not be finished very close. Muscats in early houses will have been finally thinned and should have similar treatment in every way save one, and that is the degree of heat. The temperature may range 5° higher than would be good for Black Hamburgh, although Gros Colmar will withstand and enjoy it. Late Muscats, which are this year later than usual, will now be in flower. Do not be in a hurry to tie the flower trusses down close to the wires, as large bunches often set better with their points up towards the glass. See that the roots are kept in an active condition in warm, moist borders, with brisk heat and plenty of fresh air.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Hippeastrums.—Seed-pods on the earliest plants of Hippeastrums will, in all probability, be ripe, and should be gathered and the seeds sown without delay, for fresh seeds germinate readily in a warm house. The seed receptacles should be clean and well-drained, and the compost should be of an open nature; distribute the seeds thinly and evenly over the surface of the soil, which should have been well watered previously and allowed to drain, and cover the seeds chiefly with clean, sharp sand. After sowing, place the receptacles in a warm house, cover them with a sheet of glass, and shade from bright sunshine until germination takes place. Young plants sown last year should be potted on as they require increased root space; they should be transferred to the larger receptacles with as little disturbance of the roots as possible. After potting, grow them in a light house and in a temperature similar to that in which they were growing previously. The house should be closed and the atmosphere made moist so early as the outside conditions will allow, so as to keep them in active growth. Old plants that have flowered this season should be kept growing freely and the roots liberally supplied with liquid manure. As growth approaches maturity, the plants should receive more air, and so soon as they show signs of requiring rest, water should be withheld gradually and the plants exposed fully to the sun to ensure well-ripened growths.

Chrysanthemums.—Chrysanthemum plants that are being grown to produce large exhibition blooms will now be ready to be placed in the pots in which they are to flower, but before proceeding with this operation they should have been hardened sufficiently to withstand cold winds, otherwise, when the plants are arranged in rows, some of the lower foliage may be lost. The receptacles may be from eight inches to ten inches in diameter; the larger size being more suitable for strong-growing varieties. The receptacles should be clean and well-drained, Cover the crocks with turf from which most of the fine soil has been shaken, for it is essential that the drainage should be as perfect as possible for Chrysanthemums. The compost should consist chiefly of good, strong loam, adding leaf-mould, manure from an old, spent Mushroom bed, and to each barrow-load of soil one four-inch potfull of bone-meal, the same amount of soot, and a little Chrysanthemum fertiliser; some grit or burnt ashes from the garden bonfire will tend to keep the compost open. The compost is best prepared and the ingredients thoroughly incorporated several days before it is used. Firm potting is necessary to ensure good, short-jointed growths which are essential to produce the best results, therefore the compost must be in suitable condition for it to be made firm. Should the soil be on the wet side, rather delay the operation for a day or so than attempt to ram soil that is on the wet side. The shoots should be tied to stakes secured to wire. Careful watering is necessary at this stage, and provided the young plants receive a full supply before potting, they will, in all probability, not require any more for two or three days, when they may be watered in with a fine-rosed can; spraying the plants several times daily is to be recommended, especially if the weather is hot and dry. Although careful watering is recommended, the plants must never suffer through drought. Green and black aphis are sometimes troublesome, but these pests are easily kept in check by spraying with a nicotine wash, but see that the spray reaches the crown of the plant for it is here that the aphis attacks and harms the young leaves.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Asparagus.—Strong growths will now be pushing up. Keep the beds clear of weeds and encourage weak plants by applying a quick-acting fertiliser. Soot is a useful Asparagus stimulant. Beds that were planted during the spring should now receive a light mulch of half-decayed horse manure. The Asparagus seedlings may be thinned before overcrowding takes place, while the surface soil should be stirred with a Dutch hoe and, should dryness at the roots be apparent, water the seedlings well.

Peas.—A further sowing of late Peas should be made—the variety The Gladstone being suitable. Earlier-sown Peas are now growing fast since the change in the weather, and supports should be given, the height of the stakes depending, of course, on the height of the variety; in any case, stakes a few inches higher than the approximate height of the individual variety should be employed.

Marrows.—These may now be planted. If hand-lights are available, these should be placed over the plants for a week or two until they get a hold of their new soil, when the hand-lights may be removed. Keep a few plants in reserve under cover in case late frosts injure those planted out.

Maize.—If the Maize plants, which were raised under glass, have been thoroughly hardened off, they should now be planted out in ground that has received a good dressing of farmyard manure. Allow three feet between the lines and eighteen inches between the plants. Maize delights in warmth, therefore a sunny position should be selected, and the plants should be well supplied with moisture at the roots in the growing season. As growth advances, secure each plant firmly to a stout stake.

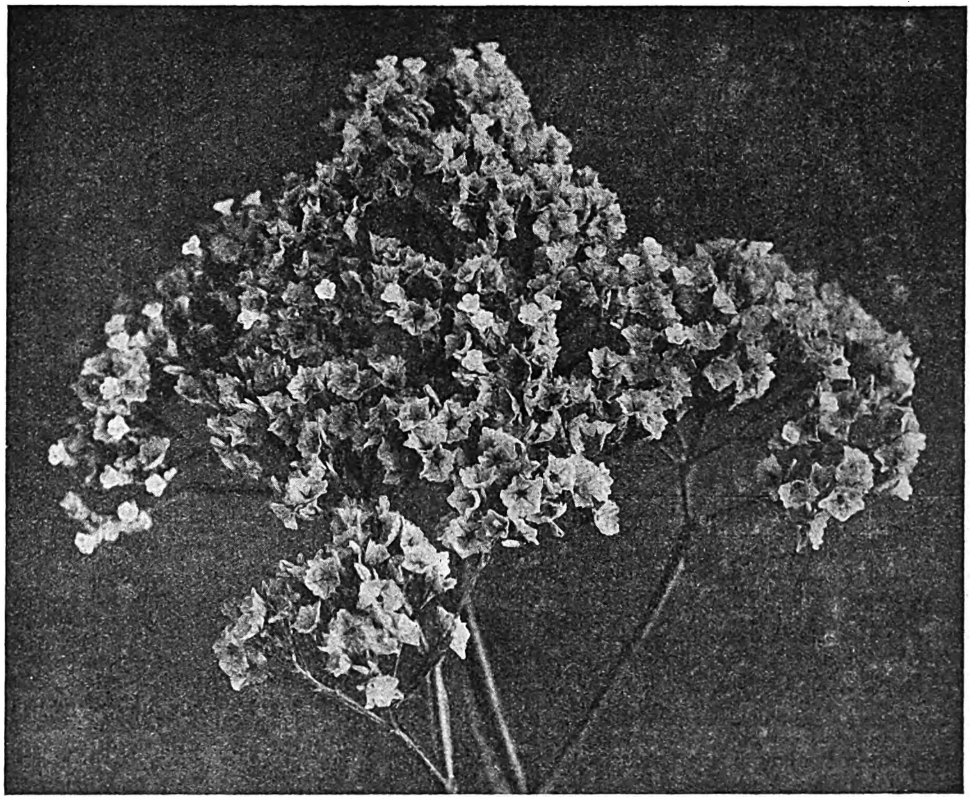

FIG. 201.—STATICE PROFUSA VAR. SUPERBA.

R.H.S. Award of Merit, Chelsea Show, May 22. Flowers blue and white. Shown by Mr. Chandler, Rolvenden Nurseries, Rolvenden. (see p. 385.)

French Beans.—Another sowing of these may be made; allow plenty of room between the plants as nothing is gained by overcrowding.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Vegetable Marrows may now be planted out-of-doors in very rich soil or, better still, on a heap of manure; give plenty of water at all times, and peg down the young growths if exposed to wind. A sowing of a good early Cauliflower should be made to fill up any spare ground, and to supply a late crop, given favourable climatic conditions. Keep the ground occupied by growing Potatos well cultivated between the rows until the haulms almost meet, when they should be earthed up finally. On heavy, retentive soil the ridges should be raised to a sharp peak, so as to throw off the rain water, while on light land a flatter top is preferable. Maintain a steady supply of Lettuces by planting frequently, as Lettuce plants soon bolt in hot weather; small sowings of all salads should be made at intervals of ten days or so. The last sowing of late Peas should be made at an early date, as these seldom come to maturity if sown later. Hoe frequently among all crops when the ground is dry and remove weeds in the rows by hand before they attain any size.

Fruit Trees.—As Apples pass out of flower they should be sprayed with arsenate of lead or orchard spray fluid to prevent attacks by the many foliage and fruit destroying pests which assail them at this stage. If heavy crops set, the fruits should be thinned severely, one fruit on a spur being quite sufficient; if large specimens are wanted even more drastic thinning is necessary. A good top-dressing of any well-balanced artificial manure, hoed into the surface, should prove beneficial, as also will a mulch of farmyard manure on light soils. Where Pear trees are subject to black spot, spraying with a weak solution of lime-sulphur (one in a hundred) should be done at intervals, and a sunless day or evening should be chosen for the application so as to avoid injuring the foliage.

Strawberries.—Spring-planted stock for fruiting next year should have all flowers and runners removed as they appear, but if there are any blanks in the rows, runners from adjacent plants should be retained to fill them. Stir the surface soil frequently to encourage free growth.

Planting Annuals, etc.—All half-hardy annuals and perennials, including Dahlias and Begonias, may now be planted in their summer quarters if properly hardened off. Have the ground well broken up and enriched with plenty of organic manure for the above-named, but many annuals, such as Verbenas, Phlox Drummondii, Chrysanthemums, Lobelia and others, make less growth, and are more floriferous on only moderately rich soils. Only water these when absolutely necessary.

INDOOR PLANTS.

HERBACEOUS CALCEOLARIAS.

Although, perhaps, not grown so much in private establishments as they were a few years ago, herbaceous Calceolarias, if grown well, always make a brilliant display with their richly-coloured, showy flowers, and they are particularly useful for the embellishment of the conservatory or flowering-plant house during April, May and June. Seeds of a good strain may be purchased from any of the leading seedsmen; a particularly fine strain for those who dislike the usual brilliant showy colours, is Sutton's Art Shades, which embraces delicate soft shades only. The seeds should be sown in May, June or July, in well-drained pans, nearly filled with rough, turfy loam, surfaced with a compost of finely-sifted loam, leaf-mould and silver-sand. Water the soil with a fine-rosed can and sow the seeds immediately, no covering being required except a sprinkling of silver sand. Place the pans in gentle heat, cover with a sheet of glass, and carefully shade them from sunshine. Germination should take place within a fortnight, and when the seedlings are large enough to handle, prick them off into pans or boxes of rich, light soil. When pricking off the seedlings, every care should be taken of those which are weakly, it being an established fact that these usually produce the most attractively coloured flowers.

When of sufficient size, pot the seedlings singly in sixty-sized pots, using a compost of light, rich loam, leaf-mould and silver sand; place them upon a shelf in an airy greenhouse and afford shade from bright sunshine. At no stage of growth should these Calceolarias be coddled or placed in strong heat; when well growing, a cold frame, with plenty of air, will suit them admirably.

So soon as the plants are well rooted they may be placed in their flowering pots, using a similar compost as before, but of a rougher nature, with an addition of old Mushroom-bed manure passed through a half-inch sieve, and a sprinkling of Clay's fertiliser. Stand the plants in a cold frame, admit air freely when possible, spray them overhead during hot, dry weather, and give shade from bright sunshine. As winter approaches, cover the frames at night if frost is anticipated, and later remove the plants to a cool greenhouse where frost can be excluded during severe weather.

So soon as is necessary, tie the growths to neat supports; pinching is not advisable as the plants make fine, bushy heads if allowed to grow naturally. Watering with weak soot-water, alternated with liquid cow manure, may be practised with beneficial results so soon as the flower buds appear. At all stages of growth a sharp watch should be kept for greenfly, to which the plants are subject, and which must be destroyed by fumigation so soon as it appears; also, if the plants are kept in a dry atmosphere and a high temperature, red spider and brown spot will disfigure them very quickly; therefore they should be grown in a cool, moist, airy situation at all stages.

Propagation may also be effected by means of cuttings, but the strains of herbaceous Calceolarias now in cultivation are so very fine, that it is labour wasted to trouble with cuttings, as the great majority of plants raised from good seeds will prove extremely satisfactory.

It is hardly possible to maintain a succession of plants in flower, as they usually bloom in May if sown as previously mentioned; the earlier the sowing, the larger the plants when in flower. *A. T. Turner.*

STREPTOSOLEN JAMESONI.

This well-known greenhouse climber is a native of north Peru, where it was discovered at an elevation of 6,000 feet by Mr. William Lobb, while plant collecting for the late firm of Messrs. Jas. Veitch and Sons, Chelsea. Messrs. Veitch exhibited plants in bloom before the Royal Horticultural Society in June, 1847, and again in 1848, under the name of Browallia Jamesoni. Eventually, it was declared a distinct species, and was given its present name—Streptosolen (*streptos*, twisted; *solen*, a tube—a reference to the corolla tube of the flower). Loudon, also, refers to it as Browallia Jamesoni. He describes it as "a showy shrubby plant four to six feet in height, bearing corymbose cymes of yellow flowers." The colour of the flowers is best described as being deep yellow, shading to deep orange with age. Moreover, the colour deepens in accordance with the amount of sunlight the plant receives.

Somehow, this fine plant did not appear to have become popular, and soon fell out of cultivation. It was re-introduced, however, about 1882, and has, since then, been more or less common, being frequently met with even as a summer bedding subject, trained as standards or loose pyramids, the pots being plunged up to their rims in the soil.

The cultivation of Streptosolen Jamesoni is comparatively simple, as it can be grown quite successfully in nine-inch or ten-inch pots. The plants are trained in standard form with stems six feet in height.

It thrives best in a compost of three parts good loam, one part leaf-mould or peat, half-a-part of dried cow manure, and enough coarse sand to keep the whole open. The pots should be well-drained, and the plants grown in a light, sunny greenhouse with a night temperature of from 45° to 50°.

But to see this evergreen flowering plant in all its glory, it should be grown as a pillar subject and planted out in a suitably prepared border, or trained against the back wall of the conservatory where it may obtain ample headroom and abundance of light. So treated, and if the growths are allowed to hang down in a natural manner, there is not a more striking subject for the conservatory than this Streptosolen when it is in bloom.

The flowers, which are produced freely in terminal heads, commence to open about the end of February, and continue to make a most brilliant show until well into June. When the flowering period is over, the shoots should be spurred back well, but where extension is desired, a few of these growths, having first been shortened slightly, should be laid in to form the framework.

The plants should be encouraged to make clean healthy growth, by strict attention to watering and syringing, and the application of stimulants, and occasional fumigations to keep greenfly in check.

The propagation of Streptosolen Jamesoni is quite simple and may be carried out now, or in July. Young shoots, three or four inches in length, taken from the main stems, root readily in any sandy mixture, if given a little bottom heat and kept shaded. The young plants should be afforded much the same treatment as are Fuchsias in the first year. *H. H. C., Reading.*

TREES AND SHRUBS.

SHRUBBY SPIRAEAS.

The genus Spiraea contains a very large number of shrubby species, many of which are charming, elegant foliaged and free-flowering shrubs, highly valuable for garden decorative purposes. They vary in height from the fifteen to twenty feet of S. arborea and S. Lindleyana, to the eight inches of S. decumbens, a dwarf, trailing species suitable for covering rocks. Like so many other Rosaceous shrubs, a considerable number flower in the spring, S. Thunbergii being one of the first, but many flower during the summer and autumn, and few other genera of shrubs provide such a lengthy season of flowering, for a selection of species can be made to maintain a floral display from March to October. These Spiraeas are useful for extensive planting in shrubberies, or for forming bold masses in the pleasure grounds and on the outskirts of the woodland garden, and many of them are admirably adapted to waterside planting.

In the matter of cultivation the Spiraeas present no difficulties; most of them are moisture-loving, but they make good growth and flower profusely in almost any deep, well-worked soil, although it may be noted that a few species, including the early-flowering S. Thunbergii and the summer-flowering S. Douglasii, do not grow so well on calcareous soils. They respond freely to liberal treatment, however, and an occasional top-dressing of manure encourages the production of long, new growths, which seldom fail to give an abundance of blossom. Strong, clean growths, however, cannot be permanently produced on plants which are left unpruned, and the importance of pruning is worth emphasising. These Spiraeas fall naturally into two groups for pruning purposes:—(1) those which flower in spring on growths of the previous year, and (2) those which flower later in the year on the current season's growths. The first group, to which belong such species as S. arguta, S. bracteata, S. discolor, S. Henryi, S. prunifolia var. fl. pl., S. media (syn. S. confusa), S. Thunbergii and S. Veitchii, and which should be pruned immediately after flowering, is generally more neglected than the second group, which includes such species as S. Aitchisonii, S. arborea, S. japonica and its varieties, S. Douglasii, S Lindleyana and S. salicifolia, as these latter are best pruned during the dormant season and are seldom overlooked. The correct treatment for these latter plants is to remove old wood and weak shoots which can be dispensed with entirely, shortening the remaining vigorous growths to prominent buds, so that the resulting new shoots can grow freely and produce their flowers when developed. Similar treatment applies to the early-flowering species, but the operation is carried out during the active growing season and, if done immediately after flowering, the goowth of vigorous new shoots is encouraged, and these have ample room for development and time for ripening to produce the succeeding year's flowers.

Of the numerous Spiraeas available, each with its peculiar attraction, and all useful where space can be found for them, the following should find a place in every collection. S. Aitchisonii, a native of Afghanistan, with immense panicles of the pure white flowers, produced in July and August; S. arguta, known as The Foam of May, and one of our most beautiful spring-flowering hybrids, its closely-set, dainty, white flowers wreathing the branches from end to end; S. canescens, a tall, elegant, Himalayan species, with long, arching branches covered with small, pale pink or white flowers in June and July; S. discolor (syn. S. ariaefolia), a North American species forming a large, but graceful bush, its plume-like panicles of creamy-white flowers appearing in July; and S. japonica var. Anthony Waterer, one of our finest shrubs for front-row massing, producing a succession of rich, carmine-red flowers from July to October.

S. Menziesii var. triumphans should be included, for it is one of the most beautiful of the late-flowering Spiraeas, its vigorous growths being terminated in spikes of rich, rosy-red flowers from July to October, and, of course, S. prunifolia var. fl. pl., a very floriferous, free-growing shrub with long, arching stems, clothed with double-white blossoms in April and May, must be planted; also S. salicifolia var. paniculata, with growths four or five feet high producing a wealth of pink-tinted blossoms from July onwards.

S. Thunbergii, a neat Chinese species, the first to flower in March, and excellent for autumn colouration; S. Van Houttei, a tall, elegant, shapely grower of French origin, producing a wealth of white blossoms in May and June; and S. Veitchii, a handsome, June-flowering species and one of the best of the newer Chinese introductions, are all worthy claimants to positions. *W. A.*

FORSYTHIA INTERMEDIA VAR. SPECTABILIS.

The Forsythias are beautiful, early-flowering shrubs of easy cultivation, and F. suspensa is a widely-grown and popular garden shrub, its long, arching branches making it an ideal subject for furnishing pergolas or pillars.

F. intermedia var. spectabilis, however, is not so well known, nor so widely grown, although it is probably the most beautiful and showy of all the Forsythias. Raised in Messrs. L. Späth's Baumschulenweg Nursery, in the early years of the present century, it soon achieved popularity and proved its ability to withstand the severe winters of northern Germany and produce its glowing masses of rich, golden-yellow flowers in spring with unfailing regularity.

Of much stiffer habit than F. suspensa, it makes an ideal bush and is effective either as a single specimen, when its uneven growths give the plant a picturesque appearance, or in groups, when the wonderful profusion of flowers provides a beautiful display which lasts for several weeks in early spring. It is easily propagated by cuttings, which may be rooted in gentle heat during July or August, and it should be planted in good loamy soil in a sunny position. *A. M. H.*

HARDY FLOWER BORDER.

DORONICUM COLUMNAE AND D. PARDALIANCHES.

At a time of the year when there is not an over-abundance of flowers in the garden, Doronicum Columnae, with its profusion of yellow, Composite flowers, is most welcome. Requiring no special treatment and being perfectly hardy, it thrives well in almost any soil, and is easily propagated by division. Its flowers are borne on stems from one foot to eighteen inches in height and are yellow; the leaves are toothed and slightly pubescent, the radical ones being stalked and almost kidney-shaped, and the lower stem leaves auricled, while the middle ones are cordate-spathulate or simply cordate. The upper leaves are ovate-lanceolate and clasp the flower stems.

Another useful species is Doronicum Pardalianches; it is a much coarser growing perennial than D. Columnae, and differs from the latter in being more hairy, the flower stems more corrugated, and the radical leaves heart-shaped. There are also fewer stem leaves, and the upper ones are sessile and clasping. The flower stems attain a height of eighteen inches to two-and-a-half feet, and the flowers are larger, although not produced so profusely as those of D. Columnae.

This species is reputed to be poisonous, as the name Pardalianches or Leopard-strangler suggests.

Both of the above-mentioned Doronicums are herbaceous perennials and natives of Europe, flowering in early spring and summer. *Reginald E. Moore, University Botanic Garden, Cambridge.*

FLOWER GARDEN.

OENOTHERAS.

The genus Oenothera contains many beautiful species of value for summer and early autumn flowering. They are mostly suitable for the margins of shrubberies or mixed borders, a few of the dwarf species doing best on the rock garden, where they attract attention by reason of their large, showy flowers, which have the added charm of delicious fragrance. They are of easy culture, but are moisture-loving plants and thrive best in soils of a sandy nature which contain a good proportion of organic matter to enable them to retain moisture. Natives chiefly of North America and the north-west portion of South America, they are quite hardy in this country.

O. biennis, the common Evening Primrose, is a North American biennial now naturalised over a wide area in this country and throughout western Europe, and has given rise to several garden forms; of these, O. b. var. grandiflora (Lamarckiana) is, perhaps, the best-known, and is a widely-grown border plant of considerable decorative value, reaching a height of six feet under favourable conditions, and producing its large, pale yellow flowers throughout the summer.

O. glauca var. Fraserii is a fine plant for the front of the border, its yellow flowers, freely produced above cushions of ovate, denticulated leaves, being very effective, while O. fruticosa is a taller plant with bright yellow flowers produced in spicate racemes from June to September.

O. missouriensis is an attractive species of trailing habit, the margins of the leaves being covered with white, silky down. O. marginata (syns. O. eximia and O. caespitosa) is probably the most beautiful Oenothera, its exquisite, pure white flowers and wonderful fragrance endowing it with enchanting beauty and interest. The flowers generally open singly in the evening and last but a day, but they follow each other in quick succession so that the flowering season extends from June to September.

O. speciosa is a tall species with suffruticose stems bearing fragrant, white flowers which become reddish as they fade; they are freely produced from June to October and are useful for cutting, while O. Youngii is a dwarf plant of compact habit, bearing deep, golden-yellow flowers of great effectiveness, and is particularly suitable for a forward position in the border.

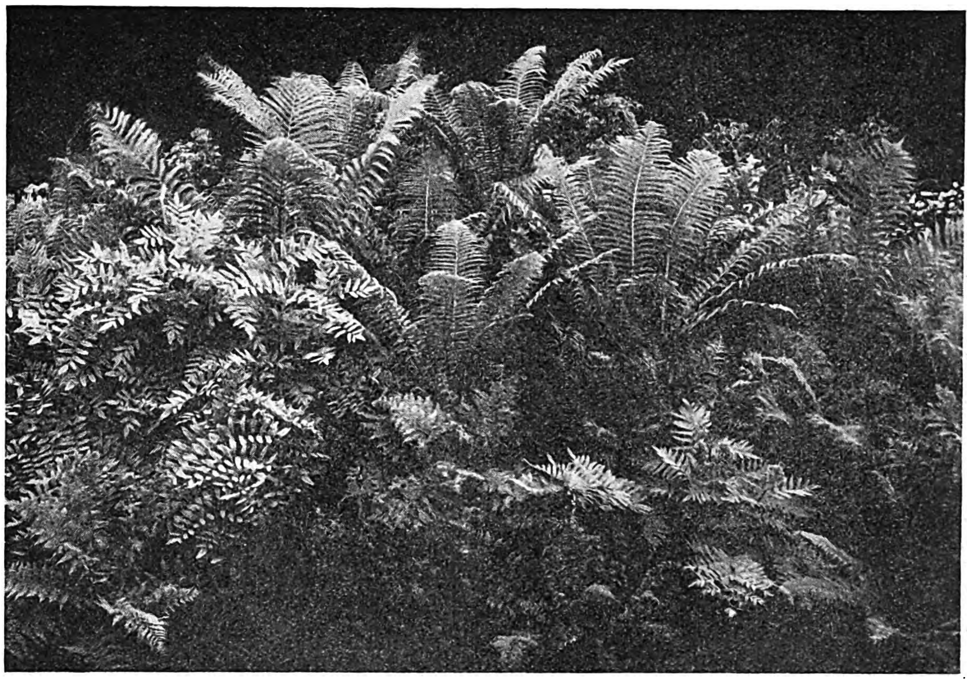

FIG. 202.—CHELSEA SHOW: MR. AMOS PERRY'S HARDY FERNS.
(see p. 389.)

There are several annual Oenotheras which are very effective, particularly in the evening, among them being O. acaulis, with large, white flowers; O. bistorta var. Veitchiana, yellow, with slight, crimson blotches; O. rosea, with rose-coloured flowers, and O. Drummondii, with yellow flowers. *A. M. W.*

BULB GARDEN.

PUSCHKINIAS.

In the garden it is necessary to look a long way ahead and to be constantly preparing for the future. One way by which this may be done is to take a note at, or soon after, the time when they are in bloom, of good plants which should be added to the garden at the proper season. Looking through the garden on April 27, the pretty little Puschkinias were still in bloom; these bulbous plants are allied to the Scillas or Squills, but are quite distinct in appearance although the popular name of Striped Squill has been bestowed upon them. They are principally natives of the Levant and have been named in honour of Pouschkin, a Russian botanist.

There is some little confusion regarding the name of the species which is the one almost monopolising the market, and which is the only one available to the many. It is usually held that its proper name is P. scillioides, and some assert that it is synonymous with P. libanotica, while others make them separate species. Viewed from a gardening point of view, this is really immaterial, so long as we get the plant we want, and this we may do by asking for P. scillioides or P. libanotica.

The Puschkinias grow to six inches or a little more in height, with channelled, lanceolate, green leaves and good-sized heads of many flowers, each nearly an inch across. They vary in colour from white to palest blue, generally lined with deeper blue, and are highly attractive. I have in my garden a plant with almost self-white flowers. There are a few varieties, but the really distinct form is compacta, which has been grown in some botanic gardens as P. libanotica var. compacta. This has larger and denser heads of flowers, but although desirable, is less graceful than the other or typical form.

P. scillioides is not by any means an expensive plant, and were there more demand for it, more bulb dealers would stock it than at present. Bulbs may be procured in early autumn and planted in light, rather sandy soil in a sunny position at a depth of from three to four inches and about the same distance apart. It may also be naturalised in grass. *S. A.*

NARCISSUS GRAELLSII, WEBB.

There is a figure of this charming little Hoop-petticoat Narcissus in the *Bot. Mag.*, t. 6,473, executed about 1870, but which, however, does the plant, as it is grown at Kew, a great injustice. The figure makes it appear to be a poor form of N. Bulbocodium, to which section it belongs.

Hailing from the Sierra de Guaderrama, the bulb is globose, and half-an-inch to three-quarters-of-an-inch in diameter, from which arise in spring narrow, linear leaves of varying length, from two to six inches, and usually two to four to the bulb. The flowers are carried singly in a sub-erect manner as in N. Bulbocodium, on short pedicels a quarter-of-an-inch to half-an-inch in length, arising from the base of a spathe which completely enfolds the ovary at the apex of a stem two to four inches in height. The ovary is somewhat boat-shaped, and three-eighths-of-an-inch long, from which arises the perianth tube an inch or more in length, funnel-shaped, and about half-an-inch in breadth at the open end, and greenish-yellow in colour, the green continuing through the centres of the segments to their apex, giving an unusual green and yellow striped effect. The segments are distinctly lanceolate, about three-sixteenths-of-an-inch in breadth at their points of attachment, six in number, and roughly two-thirds as long as the corona, carrying themselves erect until the flower nears maturity, when they tend to fall and cling around the base of the corona. The corona is half-an-inch long by as much in breadth, creamy-yellow in colour, very slightly frilled and having a fine, membranous appearance, caused by the transparent veins which run up the side. The flower has a distinct, funnel-like appearance due to the fact that the lines of the perianth tube are carried on by the corona. The whole is enhanced by the stamens, six in number, the anthers of which are of a rich golden-yellow colour, some three-sixteenths-of-an-inch in length, and attached by their centres to the tips of the filaments, the latter protruding in a declinate manner a quarter-of-an-inch from the outer rim of the corona; the style is of the same colour as the filaments but is even longer, with a slight upward tilt at its apex.

This Narcissus appears to be a very strong grower, judging by its behaviour at Kew, and once stock in sufficient quantity has been secured, it ought to be an admirable plant for the rock garden, for it produces two or three flowers to the bulb, and does well in any well-drained position in good loam. *A. Edwards, Kew.*

SCILLA ITALICA.

The Italian Squill, Scilla italica, may well be numbered among the smaller bulbs which are sadly neglected, especially nowadays, when rock gardening is so popular, as this Scilla is an excellent little subject for the rock garden, so well as being delightful in the grass or near the front of the border. It is recorded as having been first introduced in 1605, and is figured in the *Botanical Magazine*, t. 663.

S. italica is a really charming little Squill with strap-shaped leaves, six to eight inches in length, and dense, conical racemes of blue flowers, which are produced in April or May. Its height is given as about nine inches, but, as a rule, the stature is only about six inches. There is a purple-flowered variety, and other forms recorded are S. italica var. alba, white, and S. italica var. rubra, red. Although plentiful in a wild state, S. italica is little seen in gardens of this country, and is practically absent from bulb catalogues, nor have I ever seen the purple variety, purpurea, or the red or rose one, rubra, although the latter has been figured.

The white variety, S. italica var. alba, although not in bulb dealers' lists, is cultivated in a very few British gardens. The writer obtained it years ago, and lost it, but has again succeeded in securing it through the courtesy of a friend. It is very beautiful, with its conical heads of pure white flowers, and is quite hardy, but rather slow of increase, and is much prized by those who possess it. It is to be hoped that S. italica may once again come into the market. *S. Arnott.*

ALPINE GARDEN.

GYPSOPHILA REPENS VAR. MONSTROSA.

While Gypsophila repens is commonly cultivated in alpine collections, it is not so often that the lovely variety monstrosa (recorded as a hybrid with G. Stevenii, a plant, in itself, of no great decorative value) is met with. The reason for this can only be that it is unknown to many, for it is as easy to grow as G. repens, and is equally as easy to propagate, as it produces an abundance of shoots which, if secured as cuttings and inserted in a sand bed in a cold frame or under a bell-glass, from about mid-summer onwards, root readily and form good flowering plants by the following season.

G. repens var. monstrosa is, as its name would suggest, a monstrous form of the type, for it forms a bushy mass of much-branched flower stems from about nine inches to one foot high, and two feet or more through, furnished with a profusion of white flowers, sometimes faintly tinged with pink, and suggesting an exceptionally vigorous and bushy Tunica. Coupled with this charm of blossom is attractiveness of foliage, which, for a comparatively dwarf Gypsophila, is very ample and of a striking glaucous-grey, furnished by the typical waxy covering.

This lovely Gypsophila is hardy, free-growing and a good perennial, provided it is planted in full sunshine; it is ideal for planting in sunny crevices of cliffs or rock walls, or for furnishing beds in positions where it is not likely to smother more delicate subjects. *M. W.*

THE GENUS PRIMULA.

(*Continued from p.* 763.)

MOUPINENSIS (Franch.). Moupine P.

(Petiolares-Sonchifolia.)

A dwarf, perennial species with a loose tuft of thin, membranous leaves with egg-shaped or oblong-egg-shaped, blunt blades one-and-a-half inch to two-and-a-half inches long, tapering to a short, winged stalk, or almost stalkless; margins furnished with sharp, irregular, saw-like teeth; both surfaces more or less smooth. Flower stem about three inches tall, usually sparsely covered with yellow meal; it bears a terminal umbel of several pale rose-coloured blossoms. Corolla about one inch across, divided into five broadly heart-shaped, notched lobes; tube funnel-shaped, about three-quarters of-an-inch long, more than twice as long as the calyx.

Grows in elevated mountain pastures and on the margins of thickets, in north-western Yunnan, western China, and also in south-eastern Tibet.

Culture: Good loam and peat, in a damp, half-shady spot, is indicated.

MULIENSIS (Hand.-Mazz.). Muli P.

(Nivales.)

This truly magnificent, aromatic species produces a tuft of lance-shaped or oblong-lance-shaped, pointed leaves, nine to fifteen inches long, tapering to a broadly winged stalk; margins furnished with small, sharp teeth; upper surface smooth, green, under surface coated with snow-white or sulphur-coloured meal. Flower stem stout, fifteen to eighteen inches tall, bearing from four to nine fragrant blossoms on mealy stalks one to one-and-a-half inch long. Corolla nearly two inches across, varying in colour from rich rose-purple to rose-lavender, purple and violet, with sulphur meal in the throat; lobes broadly egg-shaped, notched, or at times toothed; tube yellowish-grey, funnel-shaped, about one inch long. Flowers in June.

Grows in moist, half-shady situations, on the margins and in forests and thickets of mixed deciduous and evergreen trees, especially Rhododendrons, on the mountains in various parts of Szechuan, from 11,000 to 12,000 feet above sea-level.

Culture: Grow it in rich, somewhat heavy loam, in a damp, semi-shady spot, well-drained in winter.

MULTICAULIS (Petitm.). Many-stemmed P.

(Malacoides.)

This dwarf annual is a sub-species of P. Forbesii. It forms a sparse tuft of green, orbicular-ovate leaves half- to three-quarters-of-an-inch long, heart-shaped at the base, contracted into rather slender, downy stalks about half-an-inch long; margins cut into shallow, rounded lobes, edged with sharp teeth; both surfaces clothed with minute, white hairs, more dense on the underside. Flower stems numerous, two to four inches tall, smooth bearing an umbel of ten to fifteen violet or rose coloured blossoms on slender stalks half- to three-quarters-of-an-inch long. Corolla concave, about a quarter-of-an-inch across, with heart-shaped, notched lobes; tube cylindrical, slightly longer than the calyx.

The name of the province in western China in which this plant was collected has not been recorded.

Culture: This Primula would probably succeed under the same cultural conditions as P. Forbesii.

MUSCARIOIDES (Hemsl.). Mossy P.

(Muscarioides.)

This attractive species, which is apparently biennial in cultivation, forms a rosette of somewhat fleshy, rich green, obovate-spathulate leaves three to five inches long, rounded at the tip, narrowed at the base into an obscure stalk; margins edged with broad, rounded, shallow teeth fringed with minute hairs; upper surface somewhat sparsely covered with minute hairs, underside more or less smooth. Flower stem erect, six to fifteen inches tall, frequently coated with yellow meal and bearing a dense, many-flowered spike, three-quarters- to one-and-a-quarter inch long, of deflexed, deep purplish-blue or deep reddish-blue-purple blossoms on very short stalks. Corolla narrowly funnel-shaped, about three-eighths-of-an-inch long, with egg-shaped or nearly square, slightly notched lobes; tube cylindrical, about three-eighths-of-an-inch long. Flowers in August and September. Introduced in 1906.

Grows in damp alpine pastures and in moist meadows by streams, in north-western Yunnan and south-eastern Tibet.

Culture: Grow it in peat and good rich loam in an open, well-drained position, abundantly supplied with moisture when the plant is in growth.

MUSCOIDES (Hook. f.). Moss-like P.

(Minutissimae.)

A very minute perennial species forming dense, moss-like tufts composed of tiny rosettes of egg-shaped-oblong or spathulate leaves from one-sixteenth to one-tenth-of-an-inch in length, stemless and dilated at the base; margins recurved and coarsely toothed; both surfaces more or less smooth and non-mealy. In some specimens the leaves are oblong and the teeth are confined to the tip. Flower stem almost wanting; flowers stalkless from the centre of the rosette. Corolla white or very pale blue, about a quarter-of-an-inch across, divided into five short, narrowly egg-shaped or heart-shaped, notched lobes; tube slender, cylindrical, about twice as long as the calyx. Not in cultivation.

Grows in wide patches intermingled with other extremely dwarf vegetation, in open places and in shallow soil over limestone rocks in the Kankola Pass, Sikkim Himalayas, at about 15,000 feet above sea-level.

Culture: As for P. minutissima.

MYSTROPHYLLA (Balf. f.). Hidden-leaved P.

(Dryadifolia.)

A beautiful, prostrate, evergreen species with a woody, elongated rootstock as much as six inches in length, densely clothed with the dried remains of previous season's foliage. The dense rosettes or tufts of deep green leaves have papery, elliptic, nearly circular or heart-shaped blades borne on distinct stalks twice the length of the blade, in all about three-quarters-of-an-inch long; margins furnished with rounded teeth or small lobes; upper surface sparsely clothed with minute, meal-producing hairs, underside coated with yellow meal. Flower stem under half-an-inch long, slender, erect, coated with yellow meal, bearing a solitary violet blossom immersed in the foliage on a very short stalk. Corolla flat, nearly one inch across, with wedge-shaped, bifid segments; tube cylindrical, about three-eighths-of-an-inch long. Flowers in July.

Grows in clefts in rocks and on the ledges of cliffs near Tsarong, in south-eastern Tibet.

Culture: As for P. dryadifolia.

NANA (Wall.) Dwarf Petiolate P.
(Petiolaris-sonchifolia.)

A beautiful, dwarf perennial species with the habit of the common Primrose. The somewhat small rootstock produces a rather sparse tuft of obovate-spathulate, nearly sessile or shortly stalked leaves one inch to two inches long, with their margins edged with irregular, sharp, saw-like teeth; upper surface bright, deep green frequently tinted bronze at the margins, underside paler and slightly mealy. Flower stem almost obsolete or very short, bearing about half-a-dozen Primrose-like, pale purple or lilac blossoms with a broad, white eye and a yellow mouth to the tube; they are supported on slender, slightly hairy stalks three-quarters-to one-and-a-half inch long. Corolla about one-and-a-quarter inch across, with broadly heart-shaped, entire or toothed, somewhat reflexed lobes; tube cylindrical below, slightly dilated upwards, longer than the calyx. Flowers in March and April. In cultivation in 1888 but now lost.

Grows in alpine pastures in the Himalayas, from Garwhal to Bhutan, at 10,000 to 14,000 feet above sea-level.

Culture: Good, friable loam and peat in an open, well-drained spot, abundantly supplied with water when in growth, with protection from damp in winter, is indicated.

NANOBELLA (Balf. f.). Lesser Pom-pom P.
(Bella.)

A very beautiful miniature species with tiny rosettes of spathulate leaves about three-eighths-of-an-inch long, with rounded or nearly diamond-shaped blades, blunt at the tip, gradually narrowing at the base into narrowly-winged, wedge-shaped stalks; margins edged with irregular or regular, sharp or rounded teeth; upper surface green, underside reticulate and coated with yellow meal. Flower stem about half-an-inch tall, slightly coated with yellow meal and bearing one deep bluish-purple blossom immersed in the foliage. Corolla about three-quarters-of-an-inch across, with overlapping, egg-shaped lobes cleft to the middle; tube funnel-shaped, equalling or slightly longer than the calyx, with a dense tuft of white hairs in the throat. Flowers in July. It is considered a sub-species of P. bella by Professor Wright Smith.

Grows in rocky mountain pastures on the Lichiang Range, in north-western Yunnan.

Culture: As for P. bella. *A. W. Darnell.*

(To be continued).

ADDITIONS TO THE LINDLEY LIBRARY.

The following books were added to the Royal Horticultural Society's Lindley Library during the last three months of last year:—

Aengelen, Petrus van. *De verstandige hovenier, over de twaelf maenden van't jaer* . . . Illus. 4to. Amsterdam, n.d. [16—].

Anderson, James R. *Trees and Shrubs: food, medicinal and poisonous plants of British Columbia.* Illus. 8vo. Victoria, B.C., 1925.

André, Ed. *Plantes de terre de bruyères, description, histoire et culture des Rhododendrons, Azalées, Camellias, Bruyeres, Epacris, etc.* 12mo. Paris, n.d.

Annals of Botany. Index vols. 31-40 (1917-26). 8vo. [1928].

Archer-Hind, Mrs. Laura. Trans. *See* Gothein, M. L.

Bailey, L. H. *The Garden Lover.* 8vo. New York, 1928.

Barrett, Otis Warren. *The Tropical Crops.* Illus. 8vo. New York, 1928.

Beal, Alvin C. *The Gladiolus and its Culture.* Illus. 8vo. New York, 1927.

Berlin. *Deutsche Botanische Gesellschaft.*—Berichte. Vol. 46. Illus. 8vo. Berlin, 1928.

Bolus, H. M. Louisa. *Notes on Mesembrianthemum and some Allied Genera* . . . Part I. Illus. 8vo. Cape Town, 1928.

Bostock, Frederick. *Examples of Lorette pruned Apple and Pear bushes.* Planted November, 1925, 2 and 3-year-old trees. Sm. 4to. Northampton, 1928.

Bower, F. O. *The Ferns (Filicales)*, treated comparatively with a view to their natural classification. Vol. 3: The Leptosporangiate Ferns. 8vo. Cambridge, 1928.

Brenchley, Winifred E. *Inorganic Plant Poisons and Stimulants.* 2nd ed. 8vo. Cambridge, 1927.

Britton, N. L. *Flora of Bermuda.* Illus. 8vo. New York, 1918.

Britton, Nathaniel Lord, and Millspaugh, Charles Frederick. *The Bahama Flora.* 8vo. New York, 1920.

Brookes, Gilbert. *The Complete British Gardener.* . . . 12mo. 1779.

Brown, E. T. *The Easy Gardening Book.* 8vo. 1927.

Cariot, Abbé. *Etude des fleurs: botanique élémentaire, descriptive et usuelle.* 6th ed. Vol. iii: *Flore horticole et dictionnaire.* 12mo. Lyons, 1879.

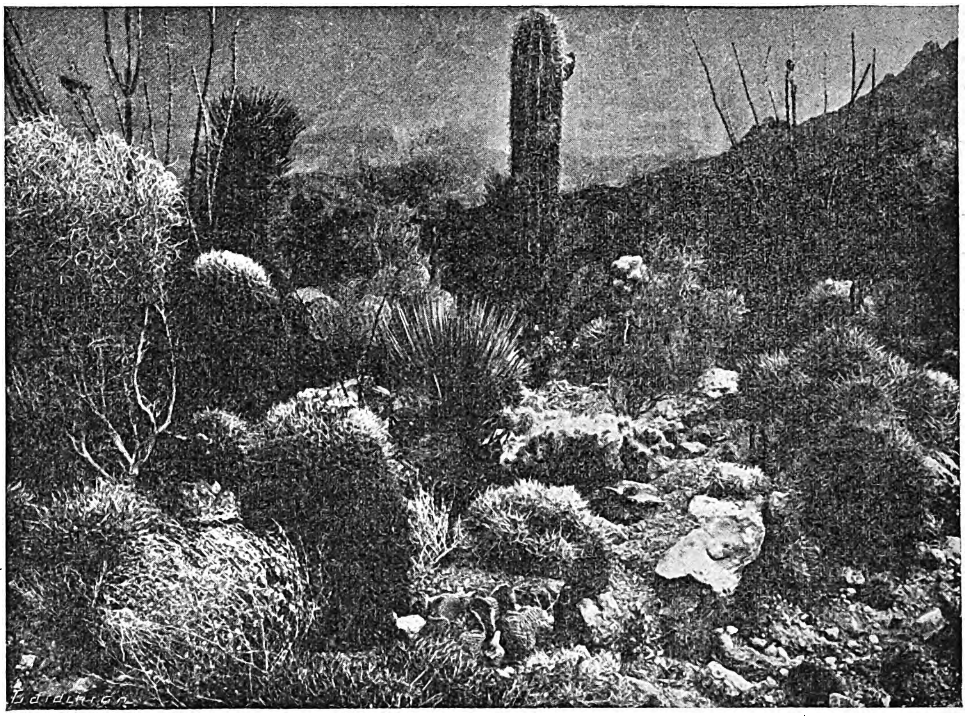

FIG. 203.—CHELSEA SHOW: A "DESERT GARDEN."
Exhibited by Mrs. A. Sherman Hoyt.
(see p. 390.)

Carpenter, George H. *The Biology of Insects.* Illus. 8vo. 1928.

Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten. Zweite Abteilung . . . Herausg. von . . . O. Uhlworm, etc. Vol. 74. Illus. 8vo. Jena, 1928.

Chanter, Charlotte. *Ferny Combes.* A ramble after Ferns in the glens and valleys of Devonshire. 3rd. ed. Col. pls. 8vo. 1857.

Chasset, Louis. *Essai de détermination des fruits (Poires).* Illus. fol. Villefranche, 1928.

Cochet-cochet, and Mottet, S. *Les Rosiers.* 3rd. ed. Illus. 12mo. Paris, 1909.

Cockayne, L. *Monograph on the New Zealand Beech Forests.* Part II: The forests from the practical and economic standpoints (N.Z. State Forest Service, Bull. 4). Illus. 8vo. Wellington, 1928.

Connoissance et culture parfaite des belles fleurs. 12mo. Paris, 1696.

Correvon, H. *Flore coloriée de poche à l'usage dans les montagnes de la Suisse, de la Savoie, du Dauphiné, des Pyrénées, du Jura, des Vosges, etc.* 2nd ed. Col. pls. 8vo. Paris, 1898.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

TULIPS.

SINCE J. G. Baker published his revision of the Tulipae in these pages* forty-six years ago, no sustained attempt has been made towards a closer consideration of the genus as a whole than Baker or his predecessors were able to make, and we are, apparently, not appreciably nearer to the birth of a monograph on the genus than was Baker himself. Dykes had the preparation of a monograph as well as a handbook of Tulips in mind for some years before his death, and as all those must who would prepare a monograph worthy of the name, had made a beginning by first-hand acquaintance with all the species and quondam species he could obtain. That he had gone a long way towards the achievement of his object was manifest when his collection of Tulip species was distributed a year or two ago. Dyke's premature death did not altogether close the door for the time to the scientific study of the genus he had in hand, for when he moved his collection of Tulips from his Charterhouse garden to that of the John Innes Horticultural Institution at Merton, his enthusiasm for the genus attracted W. C. F. Newton, of the staff of the Institution, who was willingly drawn into collaboration with Dykes in his study of the genus, and, so far as his health permitted, continued it after Dyke's death until he, too, was called.

Had these men lived, both botany and horticulture would have been the richer as the result of a brilliant association. By the time they were cut off, however—Dykes in 1925, and Newton two years later—the fruits of the work each had done and the knowledge they had gained had not taken definite shape on paper. Such fragments that exist of Dykes' exploratory work on Tulips are shortly to be published by his widow, and a summary Newton had prepared shortly before his death for a revision of the genus is now given to the world by Sir D. Hall in his recently published work on the Tulip.†

In his proposed revision, Newton followed Boissier in his division of Tulips into two main sections characterised by the presence or absence of hairs on the base of the stamens. Boissier named the first Eriostemones and the second Leiostemones, and in each there are groups of species which Newton evidently regarded as so closely related that he would have segregated some of them into clones and reduced them from specific rank. The difference between clonal rank and specific rank is well explained by Sir D. Hall, and as the term clone, although in common botanical use in the United States of late years, is comparatively new to non-technical horticultural readers here, we may offer the explanation that it represents the perpetuation of some peculiarity in a plant, by vegetative propagation, that is, by division, by offsets or bulbils, where they are formed, as in some bulbous plants, or by cuttings, but not by seed. The plant which gives rise to a clone—a "sport," for example—is itself the produce of seed resulting from the mating of the germ cell of a pollen grain with the ovule of a plant, and as many plants are self-fertilising, a single example may give rise to a clone without any fertilising by pollen from another example of the same species.

Beyond the two main sections already mentioned, there is a large group of Neo-Tulipae and Gesneriana Tulips, of which the specific position is doubtful. Some of them may be truly wild and some of hybrid origin which have maintained definite characters through prolonged vegetative reproduction. The persistent maintenance of their characters by Tulips of known hybrid origin is well exemplified by the variety called Keiserkroon, which, as the author observes, has been propagated by offsets for 150 years, without undergoing any apparent alteration.

Sir D. Hall tells his readers all that is known of the history of Tulips, the word being used to denote garden hybrids, and although, humanly speaking, as plants go, they are of barely respectable antiquity, having emerged from Turkey into western Europe less than four centuries ago, their history is curiously nebulous.

The story goes that when, in 1554, Busbequius, Austrian Ambassador to Turkey, was travelling between Adrianople and Constantinople on his way to the capital, he saw some flowers which were new to him, and in writing home about them he called the flowers "tulipam," which, apparently, was his interpretation of the word "tulband," the Turkish name for the Tulip, from its resemblance to a tulband or turban. Whether Busbequius coined the name or, as is more likely, misunderstood his Turkish informant, is not clear; but if the story is a little thin, it is the best historians have to offer of the origin of the word Tulip. Whatever the source of the name, it is tolerably clear that, on his return to Vienna eight years later, Busbequius took with him some Tulip seeds and bulbs, which he gave to Clusius, the botanist, and they were probably the beginnings of the introduction of the Tulip to western Europe, and a few years later to this country.

Exactly what varieties the first comers were is not clear, but it seems likely that they were hybrids which had probably originated ages before, and possibly by chance, in some eastern garden. The author is convinced that their source is to be found in the group of Neo-Tulipae and Gesneriana Tulips, of which the origin is uncertain. But, however it originated, it seems certain that on its first escape from Turkey to the west the garden Tulip was already a made flower, for, "except in minor points of shape and size, the garden Tulip still possesses no characters which were not present in the original introduction."

As the Tulip has altered so little in the four hundred years it has been in cultivation outside Turkey, we may regard it as an old plant. Sir D. Hall surmises that the garden Tulip may have reached Turkey from Persia, and finds some support for the theory in the fact that both Turks and Arabs call the Tulip by its Persian name—*Lalé*—a word in regular use in Persian classical literature from the tenth century, always in reference to Tulips in relation to gardens. As Persia is the native home of several Tulips and may possibly hold the matrix of the race, it requires no effort of the imagination to picture it as the home of the first garden Tulip.

Few hybrid plants have attracted such sustained interest as garden Tulips, and few, probably, have remained so little altered through centuries of propagation, or proved themselves of such incomparable value for garden purposes; so it is no matter for surprise that a considerable part of the book is devoted to them. In no sense is it a conspectus or an enumeration of Tulipae; indeed, the author expressly disclaims any attempt to deal at length with the many rare Tulip species which are seldom available to enthusiasts, and a single chapter is allotted to such Tulip species as are current coin, as it were, among the men for whom species of plants take pride of place. Their experience in the cultivation of Tulip species will not, perhaps, invariably lead them to the same conclusions as those at which the author has arrived in regard to the difficulties attendant on the cultivation of wild Tulips in general; and in accentuating these difficulties the author is unduly pessimistic. The point probably turns as much on unskilful cultivation as on our climate. Garden Tulips are almost everybody's plants, but the species are not for careless gardeners, or for cold or clammy soils; nor, for the matter of that, are species of several genera, of which the successful cultivation has been found by accident or experiment. A bad spring followed by a wet and cheerless summer undoubtedly works havoc among many Tulip species, as it does with other bulbous plants; but, in congenial conditions, which are not difficult to assure, T. dasystemon, T. Ostrowskiana, T. Kauffmanniana, T. Kolpakowskiana, T. Batalinii var. linifolia, T. persica var. Greigii and T. Sprengeri, among others, answer to careful cultivation, and the bulbs do not seem to need the early lifting and baking recommended by the author. It would, perhaps, be stretching the truth to state that T. sylvestris is difficult to eradicate, but it has an astonishing power of clinging to the ground in many out-of-the-way places.

As the author points out, any attempt to classify garden Tulips on systematic lines must fail; all that can be done is to range them in convenient groups composed of varieties of which the habit, shape of flower and flowering period coincide. This will serve well enough until, as is happening in the case of Daffodils, multiplication of varieties bridges the gaps between the groups; then, no doubt, ingenuity will find some appropriate remedy.

Signs are not wanting that the prevailing classification of the May-flowering Tulips into sections of Darwin, Rembrandt, Dutch, English and Cottage varieties has already been stretched beyond convenient limits, and with persistent intercrossing this was only to be expected. The crossing of Darwin Tulips with the Duc van Tholl varieties has produced the group named after Mendel, while another group of so-called Triumph Tulips is the result of crossing early-flowering varieties with Darwins.

The author anticipates the eventual breakdown of the classification now in general use, which, as has been already explained, is based purely on convenience, and (p. 116) proposes a revised classification centred simply on shape and colour of the blooms. No doubt, appropriate names will be evolved for the groups and subgroups, and after all, in such matters nomenclature is merely a matter of human convenience. Names for Tulips and their groups are often chosen haphazard, and forgetful of this, many must have found themselves wondering how or why Darwin's name came to be attached to a group of Tulips.

In his interesting account of the origin of the Darwin Tulips the author explains that about the year 1889 the name was chosen merely to distinguish the particular group from the old Dutch stock out of which it arose. We do not know what train of thought led Messrs. Krelage to associate the name of the savant with these Tulips, but we may, at least, regard it as a graceful compliment. The same may be stated of the Rembrandt Tulips, which are broken forms of the Darwin group.

The origin of the so-called Cottage Tulips is more obscure, and summarising the author's account of it, in what to many will be the most interesting chapter in the book, the conclusion is reached that the class was originally composed of "throw-outs" by Tulip fanciers. These discarded flowers were attractive enough to be preserved, but not sufficiently good to be included in the classes of the florists who ruled the Tulip world then. All who have raised anything themselves, animate or inanimate, will know just what is meant, and the old story of the veterinary surgeon who advised his niece, recently delivered of triplets, "to keep that one," comes irresistibly to mind.

* *The Gardeners' Chronicle*, 1883.

† *The Book of the Tulip*, by Sir A. Daniel Hall, K.C.B., F.R.S. London: Martin Hopkinson, Ltd., 1929. 21s. net

The peculiarity known as "breaking" of Tulips has always been of interest to growers, whether they regard it as a curse or a blessing, and in view of the research which has been in progress for some time at the John Innes Horticultural Institution, we had hoped that the author would have been able to make a definite pronouncement to the effect that "breaking" is the result of infection by a virus. Sir D. Hall is as yet unable to do that, but one cannot read his absorbing account (Chapter V) of the methods by which the problem is being attacked, without reaching the conclusion that it is within reasonable distance of solution.

The fact that true species of Tulips do not break may have some bearing on the question, as may the readiness of the Cottage group to break, and the comparative resistance to breaking of the Darwins. If the cause of the peculiarity can be discovered, a prophylactic will doubtless follow, and that should be of signal service to Tulip growers in meeting the demand of the day for self-coloured flowers. On the other hand, when the wheel of fashion creates a demand for broken flowers, science will show the way.

The *format* of the book is much the same as that of the Handbooks issued by the same house, but the price is more than half as much again. This may be due to the twelve coloured plates with which the volume is furnished. These are from drawings by Mr. Osterstock, and it is enough to state that the artist's fine work would have been better served by some process of reproduction more satisfactory than that chosen by the publishers. A short glossary would have helped non-technical readers to cope with such words as polyploid and hetraploid, homozygous and heterozygous, among others; and numbering of the plates would have made for convenience. The book is from the pen of a life-long student of Tulips, who has set down all he knows about it for the guidance of other students, and it is, perhaps, needless to add, that it will be the standard handbook on Tulips for many years to come.

Found in the rain forest at 8,000 feet altitude.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXII.—Retreat.

We stayed quietly in camp resting while all this was going on; I had been savagely bitten in the leg by a poisonous fly, and the subsequent swelling of the muscle had made me rather lame. Buttercup, too, was suffering from the bites of blister flies and leeches, which had festered badly. However, as May 14 seemed likely to be our last day here, I determined to return to Cha Che and follow the track so far as I could towards the pass, consistent with getting back to camp the same evening.

The weather looked far from promising, when I crossed the big torrent below Cha Che by the flimsy bridge, but the water was lower than it had been when we had crossed previously, and, in fact, I went over dry shod. I reached the ledge where we had camped in an hour-and-a-half, and finding the path without difficulty, started up the steep, wooded shoulder. A climb of some 1,500 feet brought me out of the forest into the open whence the path slanted up a wind-swept face, very steep and rocky, with scattered trees of Oak, Alder, and Birch, and clumps of Vaccinium and Piptanthus, the latter in flower; the grass was only just springing up after the melting of the snow. Presently the path plunged into forest again, where I noticed most of the Rhododendrons of this zone, but only R. arboreum in flower. The 'Irroratum' had caught it again here, as its blackened shoots testified. Then came another ascent, and a second open face, even steeper than the last, whence I reached the next shoulder, and halted, at an altitude of 8,000 feet. From here I could see some distance up the valley. I was wet through as it had been raining for some time, and the keen wind cut like a knife, until I was gelid with cold. The view was ruined by great bursts of mist which came rolling up the gorge, muffling the peaks, but I could discern the main features. Right away to the head of the valley there was no change except that the river gorge grew narrower and deeper, its walls more perpendicular, the forest more dense.

In order to avoid the cliffs, the track for some distance kept high above the river, and probably never again dropped below 8,000 feet, although a subsequent view up the valley from the Kaso ridge showed that it descended to the river again higher up, where the gorge gaped a little. Now, however, so far as the eye could see, the gorge overflowed with forest, broken here and there by drab-coloured escarpments, and the track continued up and down over these razor-backed spurs and across raw faces of open park land, dipping down into the forest wherever a torrent seared the slope, until everything was swallowed up in the clouds which clung around the pass. The final ascent must needs be precipitous. The one absolute certainty now was that the Delei valley was water worn; it never had been glaciated. Gone, therefore, was the last hope of ever establishing a summer camp near the pass. At the highest point reached, among the rocks, I found the first Primula of the year, in fruit; and although it was, I believe, only P. denticulata, had it been the most astounding Primula ever caught, I could not have greeted it with more extravagant joy! A joy which the members of the syndicate could hardly be expected to share!

On the way back to Cha Che in the forest, I saw a huge Arisaema consisting of a chocolate and silver-striped balloon of a hood, with reticulated elephant's ears on each side, protecting a spadix like a fishing rod from which trailed several feet of line. In summer the three-lobed leaf grows three feet high with a span of nearly four feet.

I reached the torrent at 4.30, only to find that it had risen several feet, and an immense wave

Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; and May 18, and 25, 1929.

was rushing over the bridge of sticks, which was twanging like a taut bow-string; I made an attempt to cross, but soon found that it was suicidal; another step, and I should certainly have crossed the Styx for good and all. So I sat down to wait, and think, ate my lunch ration, and stamped about to keep warm. At the end of an hour the water had risen slightly. I dragged some long Bamboos, which had been used to make a ladder for scaling the cliff, to the water's edge, and tried to jamb them so as to reinforce the bridge, but being unable to secure them on the other side, they were instantly torn from my grasp, and went bucking down the rapids. I saw nothing for it after that but a night out—unpleasant thought, in my wet state, without food or fire. However, when the snowfields above froze up in the early morning the water would quickly fall, and I should be able to cross.

It was now dusk. Suddenly two figures appeared on the opposite bank, one of whom was our liason officer. I shouted and made signs, and they went away, presently to reappear with a long Bamboo and a coil of creeper. A length of creeper was thrown to met the Bamboo thrust across; I got hold of it, secured it at my end with the creeper, the Mishmis did the same at their end, and behold a bridge breasting the wave! In a twinkling one of the men slid across, took my haversack, and then it was my turn. A half-inch Bamboo, with a bent sapling vibrating like a tuning fork as a hand rail, between me and Nirvana! Did I hesitate? I looked at my nailed boots—how useless in this crisis!—gripped the shaking hand-rail, and started on the journey before I had time to wonder whether, if I slipped, the force of the water would drag me from my hold or break the rail. After all, it was not far, nor particularly difficult, and I was much too cold and hungry to hesitate. I was quickly across the rapid, and leaped into the river beyond, where it was knee-deep but gentle, waded ashore, and started for camp.

It was now dark, and we hurried along, risking many a fall on the narrow track, getting in soon after seven, just as Buttercup was starting off with food and clothing to rescue me, fearing that the Mishmis had been unable to reach me; in that event first aid was to be thrown across the torrent, with a promise of assistance in the morning. My deliverance I owed to Buttercup's native wit; for, noticing a big rise in the main river, he had concluded that the torrent had also risen behind me, cutting me off, and had dispatched the two Mishmis so soon as I was overdue. His only fear was that I might have crossed a second torrent higher up the valley, in which event the rescue gang could not have reached me, so late in the day.

Meanwhile, the "Gam" from Tablekon had returned with his troops to take us back to the village; only he insisted on being paid first. As there was no time to fight this demand, I agreed, thus establishing a dangerous precedent.

May 15 was very wet, so the coolies decided not to travel, although during a lull most of the kit was taken across the river. We sat tight in our tents, and it struck me that our forces were now neatly divided—or at least, our kit was. If the Mishmis wanted to hold us up, now was their chance; but I doubt if it occurred to them. And as I came to have no very high opinion of the independent Mishmis, I will pay them this tribute now; childish, unreasonable, dishonest and obstinate as they were in many ways, when they had once undertaken to do a thing they did it. The difficulty was to persuade them to undertake anything!

The next day it was still raining steadily and never looked like stopping. The Mishmis had finished their food, and I supposed they would disperse to their villages. No, they were willing to take us back, rain or no rain, which was greatly to their credit. So we packed up our sodden tents, crossed the river, and stood by for two hours while the rest of the kit was laboriously slung over. At one o'clock we left that fatal rope bridge and started in pouring rain on the horrible climb up the cliff face of the long gorge. It was a nightmare march, and beyond satisfying myself that the golden Abelia was still there, I took no heed whatever of the vegetation; it would have required a prize indeed to have aroused any enthusiasm in me. The coolies marched and climbed up the slippery ladders like men possessed, thereby earning our grudging admiration. It was dusk when, soaked to the skin, cold, hungry, tired, thoroughly disgusted with everything, and covered with leeches, we at last reached our old camping ground in the agricultural lands of Tablekon; but the last coolies did not stagger in until nightfall. They must have been fed up!

And so ended the first round, in the complete discomfiture of the 'white hopes'! *F. Kingdon Ward.*

FERTILISERS FROM THE AIR.*

Science, speaking in the name of Sir William Crookes, predicted some twenty years or so ago that the world was approaching an inevitable food shortage. The green plant, which makes all the food of the world, could not get enough raw materials to do its work sufficiently fast to supply all mankind. Unless, then, the green plant was speeded up, man must starve. The reason why the green plant did not work fast enough was because the earth failed to supply it with sufficient raw materials. What was chiefly lacking was nitrogen. Without sufficient nitrogen in the form of salts of ammonia or nitrates, the green plant is unable to run its manufacturing process for the production of sugars and proteins at anything like maximum capacity. The green plant has to slow down and mankind, in consequence, to die down. Lack of available nitrogen has always limited life on this planet.

Now, however, science has falsified its own gloomy predictions by making combined nitrogen plentiful and cheap. In the past the supplies which the green plant used were derived from manure heaps, from the nitrate beds of Chile and from ammonia liquors distilled from coal and fixed as sulphate of ammonia. Now these supplies are every day becoming of less relative importance owing to the almost incredible rapidity with which synthetic nitrogenous fertilisers are being produced from the air.

There is, indeed, nothing new under the sun, and the marvellously ingenius inventions of scientific men which have led to this great new industry find their counterpart in the cunning contrivance of Nature herself, whereby some of the simplest micro-organisms of the soil are engaged also in making fertilisers from the air. Some of these micro-organisms make nitrates and some—the so-called nitrogen-fixers which occur in land and sea—bring the nitrogen into more elaborate combinations.

But all these natural processes are too slow for the modern world, and in the factories at Billingham in this country, and in those of Germany, France and elsewhere, nitrogen of the air is now being made into fertilisers at the rate of over one million tons per year. Although, industrially, this is a vast quantity, looked at cosmically it is a mere bagatelle; for the stores of nitrogen in the atmosphere are so vast and are being so continually replenished that at this rate of usage, Billingham and all other factories could go on doing their best for 4,000 million years without using up the supplies.

Largely in consequence of this rapid production of nitrogen, the farmers of the world are acquiring the habit of using more nitrogen and other fertilisers. Before the war, in 1913, farmers throughout the world used annually about three-quarters-of-a-million tons of nitrogen in all its various forms. In 1928, the total agricultural consumption amounted to nearly one-and-a-half million tons of nitrogen. Different nations of the world are acquiring the nitrogen habit at different rates. Holland leads the way, followed closely by Belgium. Germany comes next, employing about one-third of the amount per acre used by Holland. The fourth place in the intensive use of nitrogen is occupied by Japan, applying per acre about a quarter of the amount used by Holland. Egypt comes next and then Great Britain, which uses little more than half of the quantity that Germany applies to the acre. France lags behind England, and, interestingly enough, the use of nitrogenous fertilisers in the United States is well below that of western European countries. We have borrowed so much from the United States that it is pleasant to find that in the nitrogen habit there is something they might well borrow from us.

It is not surprising, having regard to the extension of manufacture of nitrogenous fertilisers, that the present price is low. Indeed, it might be stated that the only things which are cheap in the world to-day are nitrogenous fertilisers. This cheapness provides the farmer with the best means of reducing costs and obtaining improved economic results from his farm; for it has been shown by very full and careful experiments that the use of nitrogenous fertilisers on soils adequately provided with the other substances necessary for production, is the surest of agricultural investments. The application of 1 cwt. of nitrogenous fertiliser to the acre gives an increase of 2½ cwts. per acre of cereals and 1 ton of "roots" in the case of Potatos or Swedes; and so on for other crops.

The great factory at Billingham which is ensuring that this country shall have an adequate share in this new industry has, like the industry itself, developed at a great pace. Billingham began producing nitrogenous fertilisers in 1924, when its output (of sulphate of ammonia) was 50,000 tons. This was doubled in the following year, had increased five-fold by 1928, and is expected to reach a total of three-quarters-of-a-million tons per annum by 1930. By this date the fertilisers manufactured there will not only contain nitrogen, but also other plant foods. This work has been rendered possible by the bold forethought of Lord Melchett and his colleagues, by the genius for leadership of Colonel Pollitt, by devoted work on the part of the scientific staff which now numbers more than 150, and by the splendid support which has been given to the directing staff by the 6,000 workers already employed at Billingham—which number it is expected will be more than doubled in two years' time.

The products of Billingham are not handed on to the farmers of the Empire until they have been tested thoroughly at the Agricultural Station of Imperial Chemical Industries at Jealott's Hill, near Maidenhead. When they have proved their worth, the fertilisers are distributed throughout the Empire by the several organisations associated with Imperial Chemical Industries; thus this great industrial concern is lending powerful aid to what is, after all, the first and most essential of all industries, namely, agriculture.

---

* Summary of a Lecture given by Sir Frederick Keeble, F.R.S., at a public meeting held at the Mansion House on April 24, under the auspices of the British Science Guild.

GARDEN MANURES FOR JUNE.

In considering the value of the various artificial manures in existence, nitrogenous, phosphatic and potassic, the latter is probably the least understood and, because of this, is the least in demand, yet the increased yield and value of crops grown on land which has been well-dressed with one or other of the forms of potash are so striking that one cannot help suggesting that more could be used profitably.

It is a somewhat stereotyped dictum that all soils, and particularly the clay soils, contain a natural store of potash, far in excess of the immediate needs of the plant, and many of the text-books labour this fact; it is also assumed that this store of potash is gradually liberated during the processes of cultivation and under natural atmospheric influences, but while this is true, it may not be the whole truth. Processes of cultivation and atmospheric influences frequently fail to liberate the latent store of potash in certain soils at a sufficiently quick rate to meet the maximum needs of the plant during periods of active growth, and it is then that its artificial application, in a form which quickly becomes available, is of the utmost benefit to crops, and while this is true, to some extent, in heavy soils where sufficient potash is known to be present, it is often a controlling factor on some of the lighter lands with less potash content in any form.

The use of potash by the plant is not confined to one particular groove; it plays an important part in the elaboration of sugar in fruits, thus enhancing their nutritious value. A similar process helps in the manufacture of starch in roots, and Potatos grown with plentiful supplies of potash are stated to be of better quality and more "floury" in texture than those grown with insufficient potash. It is stated to have an intensifying effect on colour in flowers, by facilitating the secretion of the pigment which produces it, and, reasoning along these lines, it does not seem illogical to suggest that it may even facilitate the secretion of essential oils in scented plants and thus increase their fragrance, but the latter is only a suggestion, and I have had no opportunity of testing it.

Finally, it may be noted that some wonderful results have been obtained by the liberal use of potash manures on grass, and while most of these experiments have been made in the interest of food value for stock, there is abundant evidence to show that it favours the production of finer grasses and we may learn from them that in the feeding of lawns the potassic element should not be neglected.

I have on previous occasions referred to the importance of "balance" of elements in complete manures, and suggested that the potassic element does not always receive sufficient thought, therefore it may be instructive to consider its importance in relation to the health of the crop, particularly in the balance of potash and nitrogen. Experiments at the Cheshunt Research Station have demonstrated that stripe in Tomatos is caused by an excess of nitrogen in proportion to potash, and that the best antidote to the disease is a liberal dressing of potash. Similarly, there is evidence to show that chocolate spot in Beans can be kept in check by liberal applications of potash. At Long Ashton experiments demonstrated (as shown in these pages) that the winter killing of green vegetable crops was largely due to an excess of nitrogen over potash, and that the difficulty could be overcome by raising the proportion of potash in the soil. Whether other factors contribute to leaf-scorch in various crops, it is undoubtedly true that shortage of potash is not an uncommon one, and it is safe to state that the losses to growers due to leaf-scorch are much more serious than is generally supposed, for not only is the current crop affected, but those intricate chemical elaborations which can only take place in the leaf and on which the building up of the plant for the production of future crops depend, are also effectually handicapped.

It will thus be seen that a good case can be made out for the reasonable use of potassic manures and for the study of the potassic content of complete manures, in their relation to the soils on which they are to be used and the crops for which they are needed, when complete manures are preferred. The principal potash fertilisers available are kainit, potash manure salt, muriate of potash and sulphate of potash, but only the two last are suitable for application during the period of active growth and need be dealt with here. The practical difference between sulphate of potash and muriate of potash is that the carrier of potash in the former is a sulphate, while in the latter it is a chloride, and on some soils a chloride has the tendency to retard the growth of young plants; hence, although muriate of potash is cheaper—based on its unit value—sulphate of potash is generally preferred for horticultural crops grown under intensive conditions.

Some of the risks incurred in omitting to provide for an adequate supply of potash in any scheme of manuring have been shown, and where no application of kainit or potash manure salt has been made during the previous winter, and growers suspect a deficiency of potash in their soil, the deficiency can be made good by applying sulphate of potash now, at the rate of from one to two-and-a-half hundredweights per acre. Orchard trees generally, Gooseberries, Raspberries and Currants, need the heavier dressing, while the lighter dressing is beneficial to many vegetable crops, particularly Onions, Leeks, Parsnips, Turnips, Runner Beans and Celery. *W. Auton.*

HOME CORRESPONDENCE.

Gardeners' Pay and Status.—As a life-long horticulturist, I have been interested in the correspondence on the above subject. Personally, I think that a keen, hard-working gardener can usually obtain a reasonable wage for his services. I admit that gardeners' wages are generally low in comparison to the emoluments received by other workmen—bricklayers, carpenters, plumbers, etc.—employed by an owner of an estate, and I maintain that a gardener is worth as much as these. The note in your issue of April 27, p. 314, by *W. P. W.*, entitled "Gardeners' Pay and Agricultural Scholarships," opens up a very important and far-reaching subject, and I should be pleased to see a little more detail on the point. Agricultural wages are now fixed by law, and I do not think that they are, in many cases, over £2 per week; in a good many parts they are less, and I do not call this a living wage for a married man. I think I am right in stating that wages on fruit farms, market gardens, etc., are governed somewhat by the wages paid to farm hands, whose wages are, in turn, governed by the prices obtained by the farmer for his crops. The farmer states he cannot pay more because he does not get a good return for his crops, owing to foreign competition, freightage, etc., therefore the only practicable plan is to tax imported produce of this kind to such an extent that it could not be sold for less than that which is grown at home. *W. H. Clark.*

Rock Gardens at Chelsea.—In view of the correspondence and discussion during the past season on the rock gardens at Chelsea, perhaps an opinion, regarding several of this year's exhibits, by a "Fellow" who is nobody in particular, may be of interest. At Chelsea, last year, I was one of those who remarked, in connection with a certain exhibit, that those responsible for it "knew geology." Much has to be taken into account in judging a rock garden, but of this I am certain, the firm in question this year surpassed all previous efforts by creating a bit of "Nature" at Chelsea, and a pleasing, restful and harmonious bit of Nature at that. I refer to the work of Mr. Gavin Jones. Not only was it geologically correct, but artistry was well evidenced by restraint in the use of stone and plants and the balance of the whole. The only defect, to my mind, was that the lining of the near pool was too conspicuous; a matter difficult to overcome in a temporary construction. This rock garden went far to show that a minimum of large stones, well placed, is far more satisfactory than a great number of small stones. However perfectly placed, small stones give the impression of a "clatter" garden, rather than a rock garden. The exhibit which won the premier award I should have placed second. It was, I consider, very beautiful and natural, but there was a lack of restfulness, due partly to over-planting and, especially, to the rather large piece of rock just below the top on the extreme left; this latter sadly disturbed the balance of a beautiful lay-out, and could well have been omitted. Some years back Mr. Whitelegg put up some wonderful exhibits. Why does he now persist in the jumble of limestone blocks with intensive planting so unworthy of his capabilities? And why do exhibitors make a public parade of their gardens? So distracting and unnecessary, for plants can be seen far better on a show table, amid rocks if desired, in the tents. After all, is it not the purpose of the outdoor exhibits at Chelsea to display gardens as a whole? I should state that I do not know anybody even remotely connected with the various rock garden exhibitors at Chelsea. Finally, I must state that I, for one, was extremely appreciative of Mrs. A. Sherman Hoyt's intensely interesting Californian exhibit. *R. Painton.*

SOCIETIES.

CHELSEA SHOW.

(*Concluded from p.* 393).

Hardy Herbaceous Plants.

To the people who love hardy Primulas, the collection of these plants set up by Col. and Mrs. Kemmis, Lymington, Hants, was one of the most attractive features in the show. In the extensive variety there were Primulas helodoxa, hybrida Mrs. Kennis, Joey, japonica var. Miller's Crimson, japonica var. alba, burmanica, Asthore hybrids and others; truly a charming collection.

With the golden-yellow of Trollius Earliest of All, Commander-in-Chief, Orange Crest, Empire Day, His Majesty, Goldquelle, and varieties of Lupins prevailing, the display of hardy flowers made by Messrs. Harkness and Sons was very attractive. A collection of flowers from the Little Munden Nursery contained a mixture of Delphiniums, Tulips, Violas, Solomon's Seal and other flowers.

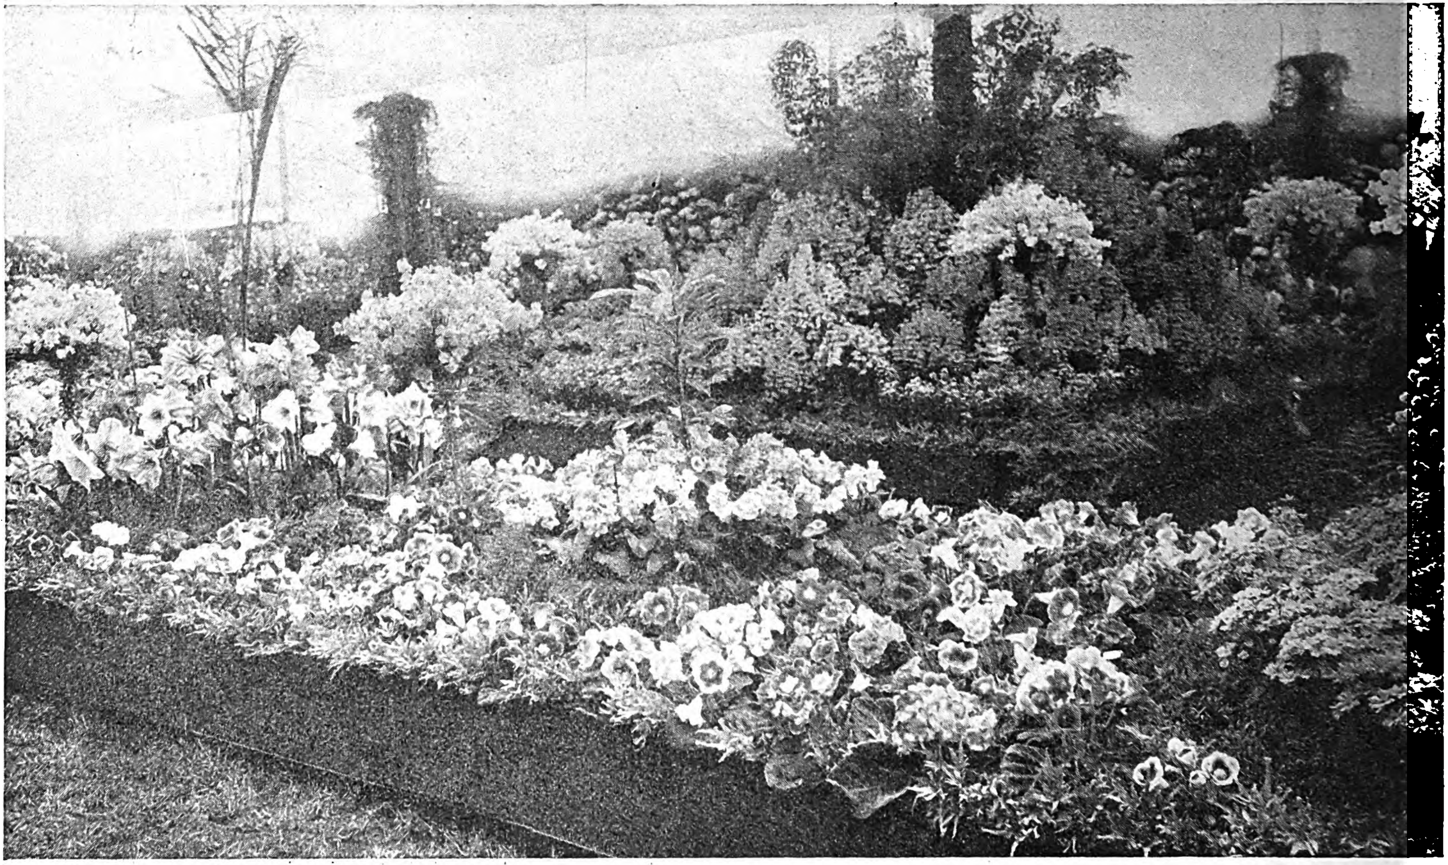

FIG. 207.—CHELSEA SHOW MESSRS. JAMES CARTER & CO.'S GOLD MEDAL EXHIBIT.

(see p. 386.)

Highly attractive on account of its free-flowering habit and deep lemon colour was the display of Primula Barrowley Gem shown by Mr. R. V. Roger. Quite unique was the group of Pentstemon heterophyllus var. True Blue, shown by Messrs. I. House and Son, who also showed Pink White Lady, Verbenas and other plants.

In one corner of the tent Messrs. Bakers made a fine display and the material used in the collection included tall Delphiniums, Lupins in variety, Campanulas, a number of named varieties of Trollius, a group of Lilium umbellatum, with Japanese Maples and Bamboos in the background. The effect of this display as a whole was very charming. The same firm also showed a group of Spiraeas, the different varieties showing various shades of rose and pink.

A mass of Lupins from Messrs. John Waterer, Sons and Crisp occupied a position of prominence near the entrance to one of the tents, and among the varieties represented were Delight, Iolanthe and Sunshine; Delphiniums, German Irises, Pyrethrums and Verbascum Cotswold Gem added an air of variety to this charming display of flowers.

With flowering specimens of the curious Beschorneria yuccoides at the back, as well as Embothrium coccineum, the Fire Tree, and Myostodium nobile, the Chatham Island Forget-me-not, Messrs. R. Gill and Son showed a fine and interesting collection of St. Brigid Anemones. The bank of Lupins from Mr. G. H. Dalrymple made an effective display and next to them the same firm set up a fine collection of hardy Primulas, in which Primula hybrida Sir George Thursby made an attractive centre piece. St. Brigid Anemones, Violas, Pansies and Papaver May Queen, which resented the heat of the tent, were the chief features in the exhibit from Mr. F. Rich.

An interesting group of hardy plants was artistically arranged by Messrs. B. Ladhams, Ltd., and the chief features it contained were Primula Sieboldii var. grandiflora and the pretty little double Myosotis Bijou. A very interesting group of hardy herbaceous flowers, with Water Lilies in bloom, in water, looking very natural with gold fish swimming among them, was shown by Mr. Amos Perry, and not the least interesting part of it were the Irises, Paeonies and Trollius giganteus.

Delphiniums in variety, Anchusas Pride of Dover and the Dropmore variety, Lupins, Aquilegias, Verbascum Gainsborough, and Geums were the chief features in the collection that was tastefully arranged by Messrs. W. Wood and Son. Lupins formed the background and Aubrietia Drayton the ground work of a small exhibit sent by Mr. G. R. Downer, Chichester.

Pyrethrums, both single and double in considerable variety, with Delphiniums, Paeonies and Lupins, comprised the flowers mostly used in the group set up by Messrs. J. Kelway and Son, with Gladioli Early Sunrise, Duke of Bedford and others in the centre, the whole making up a very charming display.

From Messrs. G. Gibson and Co there came an interesting collection in which an Iceland Poppy called Gibson's Giant Orange was a feature. Delphiniums were a feature in Mr. S. J. Goodliffe's collection of flowers, and at one corner of the group there was a well furnished rock garden. Paeonies alone made one group from Messrs. G. Bunyard and Co. and some very pleasing varieties were displayed, including Reine Hortense, Marie Jacquière, Arthur Claude Lorraine, Cingalle and many others. In a group staged by Messrs. G. and A. Clark there were masses of Trollius giganteus, Astilbe Granat, Doronicums, Irises in variety, Geums, Campanulas and Thalictrums. From the Maytham Gardens, Rolvendon, came a charming collection of Campanula persicifolia, and the Studley College sent a showy collection of Canterbury Bells.

Not the least attractive exhibit to be found in the tents was the wonderful display of Delphiniums from Messrs. Blackmore and Langdon, which not only demonstrated the development that has been made in the culture of these plants, but it represented the wide range of delicate colours provided in the many named varieties. It is, perhaps, safe to state that Messrs. Blackmore and Langdon never set up a finer early lot of Delphiniums.

Messrs. Hewitts also made a great show with Delphiniums, which were admired by al who saw them. The level of the flowers was so equal that there would be no point in selecting any of the varieties particularly for mention.

A well-arranged group of hardy plants arranged by Messrs. Bees, Ltd., contained masses of Campanula Telham Beauty, Trollius Excelsior and Earliest of All, Pyrethrum Firefly, Irises Hart Nibrig and Yellow Queen, with a mass of hybrid Aquilegias, Lilium umbellatum and Geum Fire Opal.

Delightfully attractive are applicable words to describe the exhibit of Messrs. Wilson and Agar, which was composed of Lupins in charming variety, Astilbe Rhineland, Campanula The Shirley and C. Verdun, and Verbascum Cotswold Queen, all displayed to advantage without any overcrowding.

Messrs. M. Prichard and Sons, Ltd., had a miscellaneous collection of hardy plants in which were included Erica australis, Eremurus himalaicus, Lupins in variety, Primulas japonica, Garnet, Red Japanese Blush, and Hew Dalrymple, Magnolia Lennei and Saxifraga pyramidalis. Lupin Downer's Delight was one of the most charming varieties displayed.

Plants of Special Interest.

As is usual at the Great Spring Show of the Society, a large number of plants were submitted to the two sections of the Floral Committee. The majority failed to receive recognition, and we imagine that most of the knowledgeable visitors were in agreement with the findings of the Committee as regards the average rejected plants, and would wonder why the owners of a few brought them to Chelsea. But among the plants which, no doubt for good and sufficient reason, did not receive award, there were some which possessed a certain garden value. Salvia Simmonsii, which was shown by Messrs. Chaplin Bros., and was stated to be a sport from the well-known S. Pride of Zurich, appears to be a very desirable variety of the scarlet S. splendens for cultivation in pots or for summer bedding. It is of dwarf, compact habit and bears large, brilliant flowers. Dianthus Sweet Wivelsfield is a graceful hybrid raised by Messrs. Allwood Bros. It is erect, branches freely, and two or three of the plants bore very attractive flowers. Trollius Golden Monarch, shown by Messrs. G. Gibson and Co., is a vigorous variety, well furnished with bright golden-yellow flowers. Mimulus Painted Lady, shown by Mr. Clarence Elliott, is one of the large-flowered Musks. It has creamy-white flowers with a bright crimson blotch and margined with velvety-crimson.

Cupressus obtusa tetragona minima was shown by Messrs. W. H. Rogers and Son, who claimed that it is the dwarfest Conifer; in addition to its exceeding dwarfness, it was a very compact and healthy specimen. Veronica austriaca, shown by Mr. T. Carlisle is a charming little herbaceous plant, about two inches in height, and bearing spikes of relatively large, bright blue flowers.

Rhododendrons and Azaleas.

Whether in the tents or out-of-doors, the massed groups of Rhododendrons and Azaleas were especially valuable in the wealth of glowing colour they supplied. The dry winter and spring have not been altogether favourable for these shrubs, and more particularly the evergreen Rhododendrons, but Messrs. Waterer, Sons and Crisp were able to set out two excellent groups of Rhododendrons, with an occasional specimen of a Japanese Maple, at the Embankment end of the large marquee. They had very large and profusely-flowered specimens of Bagshot Ruby, of brilliant colour; Starfish, a very beautiful light pink variety which has prominent stamens; Glory of Bagshot, a lovely white which retains the pink flushing of the buds on the outsides of the petals; Prince of Wales, light pink with deeper colour on the margins; Monstrous, a really immense truss of large flowers of fascinating pink shades; Britannia, vivid scarlet; Philip Waterer, a large flower of bright pink shading; Cynthia, deep pink, with cerise spots; Bernard Crisp, pink; Mother of Pearl, a delicate blush which becomes almost snow-white when fully open; Mars, a deep red; Ida Waterer, a bright crimson with waved margins; Saturne, cerise, shading to pink; Loder's White; Mrs. E. C. Stirling, which is still one of the best Rhododendrons of pink colouring, and the equally well-known Pink Pearl.

In association with their attractive groups of Liliums and other border plants, Messrs. Wallace and Co. showed a number of good Rhododendrons. The principal sorts were Pink Beauty, Doncaster, bright red; Mrs. R. W. Wallace, pale blush, freely spotted; Sappho, white, with chocolate spots; Admiral Piet Hein, blush-lilac; Duke of York, rosy-pink with brown spots; Corona, coral-pink shades; Barbara Wallace, rich pink with deeper shading on the margin; Pink Pearl and White Pearl. At one corner of the group they showed a few well-flowered Camellias.

A large corner in the marquee was filled with Rhododendrons by Messrs. Fred. Street. The varieties of bright colouring included Meteor, Mars, Bagshot Ruby, Prometheus and Corona, and they also had good examples of Pink Pearl, Mrs. E. C. Stirling and John Waterer.

In one of the corners of the marquee at the rock garden end, Mr. W. C. Slocock grouped many interesting Rhododendrons. His collection included some particularly good hybrids of R. discolor, R. campylocarpum and R. auriculatum. The outstanding named sorts were Professor Hugo de Vries, an immense flower of pink colour shaded with lilac; Goldsworth Pink, Cynthia, blush, and Langley Park, bright crimson. In the open, Mr. Slocock had another very good group of Rhododendrons, and in this the centre was filled with profusely-flowered bushes of Goldsworth Yellow. Professor Hugo de Vries was again well shown, as also were Alice, Mount Everest, Cynthia and Madame B. de Bruin, a bright red.

Many Rhododendrons, chiefly hardy hybrids, were staged by Messrs. R. Gill and Son, but they also had several plants of R. sino-grande to show its exceedingly luxuriant leaves. Their hybrids included Pink Pearl, Lady Ethel Hall, pink, with deeper shading at the margins; Betty Wormold, a large flower of pink shades; and Mrs. A. T. de la Mare, a good white.

In association with an interesting collection of uncommon plants, Lady Aberconway (gr. Mr. F. C. Puddle), Bodnant, North Wales, displayed some good Rhododendrons. The chief were R. Wiltonii, R. campylocarpum, R. callimorphum, R. oreotrephes and R. (Azalea) Vaseyi.

Deciduous Azaleas of great beauty were shown by Messrs. R. and G. Cuthbert in the marquee, and in the Main Avenue. Their exhibit in the marquee filled two goodly beds, and the outdoor collection was even more extensive. All the types and crosses were represented by the best sorts, and they were all of entrancing beauty. Among the mollis × sinensis were Brilliant, Dainty and Hugo Koster, of glowing colours, while the A. rustica varieties included A. Mecene and the double, blush-pink A. Ribiera. In addition to the many Azaleas the outdoor group contained a number of good Hydrangeas and Lilacs.

At the Hospital end of the marquee, Mr. George G. Whitelegg had a very attractive group of deciduous Azaleas. This included Dante, Gabriel Rosetti, pink and pale primrose; Mrs. George Whitelegg, yellow, flushed with red; Professor Lorentz, orange-red with yellow centre; Mutatuli, orange shades; Beethoven, salmon-orange; Samuel Taylor Coleridge and several very beautiful Kaempferi × malvatica seedlings.

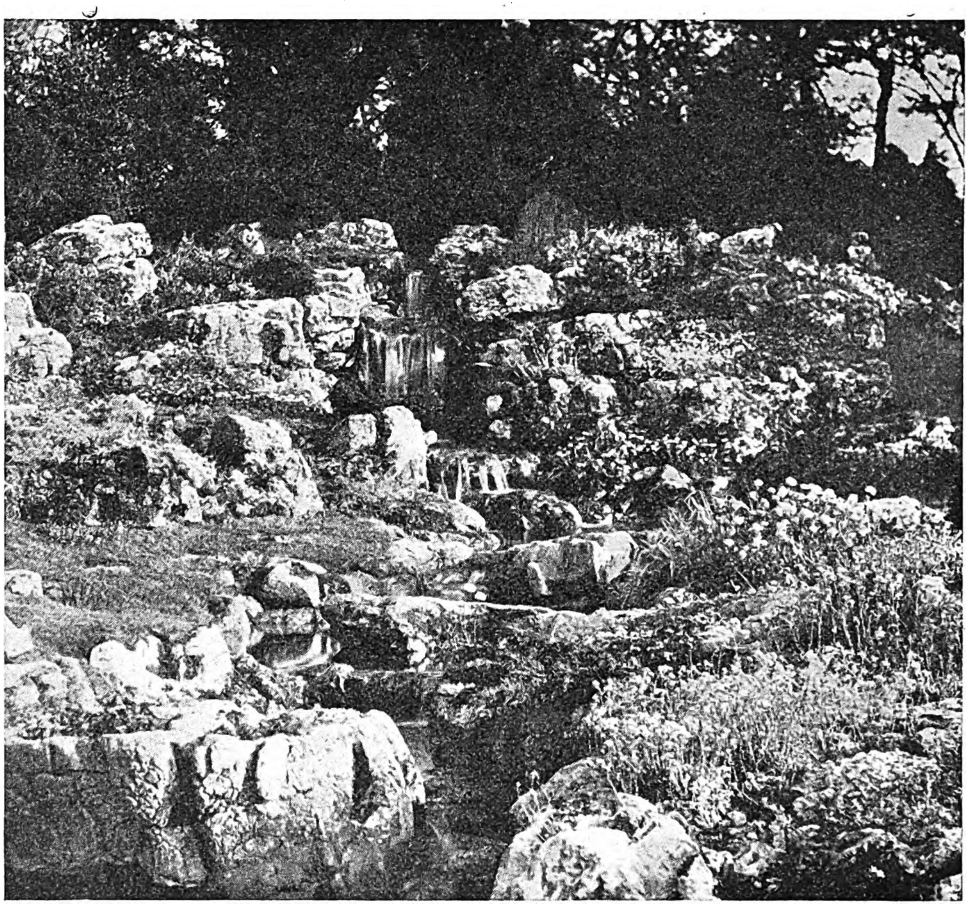

FIG. 208.—CHELSEA SHOW: MESSRS. PULHAM AND SON'S ROCK GARDEN

(see p. 386.)

Trees and Shrubs Out-of-Doors.

A very attractive finish to the rock gardens was made by the groups of miscellaneous shrubs which were arranged at the ends. By the small gate, Messrs. Hillier and Sons had a most fascinating display in association with their pleasant "Rivulet Garden." Large specimens of Japanese varieties of the double-flowered Cherries were freely used and with great effect. These floriferous bushes were chiefly varieties of Prunus serrulata and of P. Lannesiana. Many Brooms, Japanese Azaleas, and shapely Conifers were also well placed. On the bank of the rivulet there was a good example of the prostrate Salix herbacea, one of the most lovely trees in existence. Many Primulas, Astilbes, dwarf

Irises, Lychnis and other appropriate plants were given places on either side of the rivulet, while in the water were various Nymphaeas, Rushes and Reeds.

At the other end of the rock gardens, Messrs. Fletcher Bros. set out many good standard Brooms over shapely young Conifers. The latter included varieties of Cupressus, Thuya, Juniperus and Taxus, mostly of value for the rock garden.

A large collection of hardy trees and shrubs was well arranged by Messrs. A. Charlton and Sons. The chief flowering sorts were Brooms, Rhododendrons, Azaleas, Corokea virgata, Kalmia latifolia, Viburnum Carlesii and Laburnum Vossii, while colour was also provided by many shapely Japanese Maples. The Brooms were mostly standards of such varieties as Daisy Hill, Firefly, Dallimorei and Dorothy Walpole.

Another uncommonly good exhibit of hardy trees and shrubs was made by Messrs. Waterer, Sons and Crisp. In one large bed they showed many double-flowered Cherries, Lilacs, Brooms, Prunus japonica var. roseo pleno, Rhododendrons, Azaleas, Ledum palustre and Japanese Maples. A companion bed was filled chiefly with very healthy Conifers. Those of good yellow colouring were prominent and included Cupressus pisifera var. filifera aurea, Taxus Standishii, Taxus baccata var. nana aurea, and Cupressus obtusa var. Crippsii. There were also good examples of Abies concolor, Cedrus atlantica, Cedrus Deodara and many desirable varieties of Cupressus Lawsoniana.

A large, main bed with several smaller round beds were well filled with hardy trees and shrubs by Messrs. L. R. Russell, Ltd. The ornamental Vines were freely shown, and the chief sorts were Vitis heterophylla variegata, Vitis aestivalis, Vitis Ciotat, Vitis arborea, and Vitis Coignetiae. In one group there were many very fascinating bushy Wistarias in full bloom.

A very bright and attractive group was arranged by Messrs. Hewitts, Ltd., with many Laburnums, Brooms, Rhododendrons and Azaleas. The Rhododendrons included good specimens of Loder's White, Princess Mary of Cambridge, Snowball and R. fastuosum var. flore pleno.

Their customary extensive collection of Japanese Maples was set out most attractively by Messrs. W. Fromow and Sons. The many specimens were all grown splendidly and well illustrated the great charm and value of the diversity of foliage and colour of these shrubs. Those with most brilliant colours included Acer dissectum atropurpureum and A. palmatum atropurpureum sanguineum, while the delicate beauty of the pale green A. dissectum palmatifidum was a perfect foil to the vivid colours. Other good varieties which were so well shown included A. japonicum aureum, A. pictum album and A. dissectum ornatum.

A very effective group was made by Messrs. M. Prichard and Sons with various Brooms, Lilacs, Magnolias, Potentillas and other flowering shrubs in association with excellent Lupins, Geums, Primulas, Trollius, Tiarella cordifolia and other border flowers. A small round bed was filled by Messrs. Isaac House and Son, with the beautiful Pentstemon heterophyllus True Blue, edged with the deeper coloured Anagallis linifolia Willmoreana.

There were many very shapely topiary specimens, mostly in evergreen Box, and standard Bay trees of high quality. With their excellent "Cutbushes" Messrs. W. Cutbush and Son grouped large batches of Hydrangea Madame E. Moulliere, H. Viscomtesse de Vibray, H. Marechal Foch and H. Rubis. Messrs. Robert Green (1911), Ltd., had a very extensive exhibit of perfectly-trained topiary specimens, and also showed many stately Bay trees. Similar specimens were also set out by Messrs. Harrods, Ltd., and Mr. J. Klinkert had his customary large exhibit of topiary in many forms, mostly in Box, although a few were of Yew.

Trees and Shrubs under Canvas.

A large and very attractive group, solely of Clematis, was exhibited by Messrs. G. Jackman and Sons. This was composed of exceedingly well-grown plants bearing plenty of large flowers. The many varieties included Ville de Lyon, bright carmine-red; Marcel Moser, mauve, with a pink stripe; Duchess of Edinburgh, double, white; Comtesse de Bouchard, satiny rose, very free flowering; Belle of Woking, pale mauve; Beauty of Worcester, blue; Lasurstern, large, bright blue; Fairy Queen, pale flesh-pink; Miss Bateman, white, with chocolate filaments; Princess of Mauve, bluish-mauve; The President, plum shades; Lady Betty Balfour, velvety-purple; Lady Caroline Neville, white and mauve; Lady Northcliffe, deep blue; and the popular Nelly Moser.

At the Embankment end of the marquee an extensive and exceedingly attractive collection of trees and shrubs was arranged by Messrs. Hillier and Sons. As in their outdoor exhibit the beautiful flowering Cherries were well represented. They also had large bushes of the yellow Rosa Hugonis, many Hydrangeas, Pentapterygium serpens, and an interesting selection of the rarer Conifers, such as Taiwania cryptomerioides, Cunninghamia Konishii, C. sinensis, Pinus patula, P. Montezumae, P. Lindleyi and other Mexican Pines.

A large collection of the rarer trees and shrubs was set out by Mr. G. Reuthe. At the ends of this noteworthy exhibit he had exceptionally large specimens of Crinodendron Hookeri and Lomatia ferruginea, while in the centre there was a flower spike of Beschorneria yuccoides and another of Echium Wildpretii. There were also flowering branches of Cestrum coccineum and several of the best deciduous Magnolias. Rhododendrons were represented by large bushes of Pink Pearl, Hugo Koster, Aucklandii var. album and other desirable sorts.

In a corner of the marquee, a good collection of hardy shrubs was displayed by Mr. R. C. Notcutt, who had tall examples of Pyrus Scheideckeri, P. Lemoinei and other Pyruses, with some double-flowered Cherries, Brooms, Enkianthus campanulatus and, in Victor Lemoine, Belle de Nancy and Vauban, three good Lilacs. On the staging, Messrs. Robert Veitch and Son showed Lilacs Charles Joly, Jeanne d'Arc and Congo, with Magnolia cordata, Sollya Drummondii, Andromeda Rollinsonii, Metrosideros floridus, Illicium religiosum, Grevillea sulphurea and other half-hardy shrubs.

A very good collection of Brooms was shown by Messrs. William Watson and Sons. The outstanding varieties were Lord Lambourne, scarlet-crimson wings and creamy-primrose standards; Lady Moore, rich, fiery red wings and yellowish-buff standards; Hibernia, velvety-crimson wings and creamy-orange standards; Eblana, brick-red wings and crimson standards; Dorothy Walpole, velvety-crimson wings and rose standards; and many of the best of the older sorts. Messrs. Burkwood and Skipwith showed Brooms, Azaleas, Rhododendrons, Kalmias, Maples, Daphne caucasicum and Leptospermums. The Lye Green Nurseries had various Lilacs, Cherries, Maples and dwarf Conifers. A compact group of Crataegus, Ribes aureum, Rhododendrons, Azaleas, Veronicas and Rosemary was contributed by Messrs. Patricks. Mr. George E. P. Wood showed Brooms, Rhododendrons, Azaleas and other hardy shrubs.

On the tabling, Mr. C. Turner showed such good Lilacs as Souvenir de L. Späth, Le Galois, Marc Micheli, Senator Volland, Marie Legraye, Negro and Michael Buckner. Messrs. W. J. Brown also showed a good selection of Lilacs, with Heliotrope Lord Roberts, Tropaeolum Ball of Fire and Trollius Golden Queen. Messrs. D. Stewart and Son included, in a miscellaneous group, Kalmia latifolia, Japanese Azaleas, Genista praecox, Olearia stellata, several good Rhododendrons and Japanese Maples. In a large corner space, Messrs. J. Cheal and Sons grouped large specimens of the varieties Mary, Frieda, Gerda and Auguste of Japanese Azaleas, with various Brooms, Rhododendrons, Viburnum Carlesii, Kalmia latifolia, Cytisus Andreanus, C. Golden Sunlight, C. kewensis and C. purpureus var. pendula.

A very complete collection of dwarfed Japanese trees was staged by the Yokohama Nursery Co. Many of the specimens were evidently of great age, yet all were in perfect health and possessed considerable beauty of form. The oldest examples were of Cupressus obtusa, although the Wistarias, which were bearing long racemes of flowers, the Maples, Pines and Larches, were quite ancient.

The Leptospermums were very prominent in the interesting group of the Donard Nursery Co., who had profusely flowered bushes of L. Nichollii, L. scoparium and L. Chapmannii, and also included heavily-fruited bushes of Pernettya Bell's Seedling. Interesting shrubs were also shown by Mr. W. J. Marchant and Messrs. Hollamby's Nurseries.

Miscellaneous Plants.

A large circular group of exceedingly well-grown Dahlias was arranged by Messrs. Carter Page and Co. Here they displayed full-grown pot plants of nearly all the different types of the autumn flower. Cut blooms of various Dahlias were shown by Messrs. E. F. Fairbairn and Sons.

An extensive collection of especially good Auriculas was staged by Mr. James Douglas. The alpine varieties, which have decided garden value, predominated, but the show and fancy varieties were also well represented.

Violas and Pansies were equally well shown by Mr. William Yandell, who had many trays of blooms of distinct varieties kept fresh in moist sand. Mr. G. Zambra also exhibited Viola cornuta seedlings. A small collection of greenhouse Fuchsias was set up by Mr. H. A. Brown. Mr. R. J. Case had trusses of many useful Zonal Pelargoniums, and Mr. T. M. Endean set out a fascinating collection of Cacti, mostly as small pot plants, although there were some large Mammillarias. An attractive little rock garden on the tabling was made and planted by Messrs. Casburn and Welch.

The Scientific Tent.

The large tent which contained the more recent contributions to the science of horticulture received its full quota of interested and inquiring visitors throughout the three days of the show. In most instances there were representatives of the various establishments ready and willing to help the enquiring visitor.

The East Malling Research Station had four ten-year-old Apple trees which had been lifted carefully so as to show every possible root intact and in its natural direction. The four trees were on different root-stocks and had been grown on the Bagshot sands at Wisley. The chief object of the exhibit was to illustrate how great an influence the stock has on the vigour and spread of the fruit tree and, according to the nature of the root-stock the same variety (Lane's Prince Albert in this case) may be made very vigorous, vigorous, semi-dwarf or very dwarf. The exhibit taught other lessons, particularly that the spread of the roots is considerably in excess of that of the branches, and that the root system is composed of a scaffolding of main branches from which other roots descend almost vertically, and that from these, fibrous roots ramify in all directions.

The Seale-Hayne Agricultural College had an interesting exhibit concerning various diseases and pests of bulbs, and the chief were Narcissus flies, Narcissus eelworm, Narcissus leaf-spot and Tulip basal rot.

The Rothamsted Experimental Station's exhibit was in three sections, (1) Plant Diseases; (2) the Insecticidal Properties of Plant Extracts; (3) the Activities of the Useful Micro-organisms concerned in (a) the inoculation of Leguminous plants, and (b) the manufacture of artificial farmyard manure. The last-named showed that a fair substitute for farmyard manure may be obtained by the proper use of such materials as garden refuse, bracken and straw.

The Cheshunt Experimental Station showed specimens of injurious gall midges, particularly those which affect the Pear and the edible Pea; various diseases and pests of certain greenhouse plants, such as red spider and white fly on Tomatos, the leaf-miner of Chrysanthemums, and the mosaic disease of Aucubas.

The chief exhibits of the R.H.S. were "Insect Pests of New Garden Plants," showing how they may be combated; diagrams illustrating the effects of the length of day period of illumination upon growth; the eelworm disease of Narcissus and methods of control; fungus diseases of various garden plants, trees and shrubs; the "Determinations of groups of Plant Pigments"; specimens of manures and fertilisers in common use; and eight coloured drawings of Bearded Irises, illustrating the colour classification of this race of Irises. The Society's Information Bureau, where representatives were prepared to throw light upon the Fellows' troubles and problems, was again well patronised.

The Director of Kew sent herbarium specimens of plants from the Balkan Peninsula—a phytogeographical study; and from the Edinburgh Botanic Garden were sent many excellent new and interesting photographs of Scottish arctic alpine plants in their natural habitats, and also many photographs of new garden plants of more than usual interest.

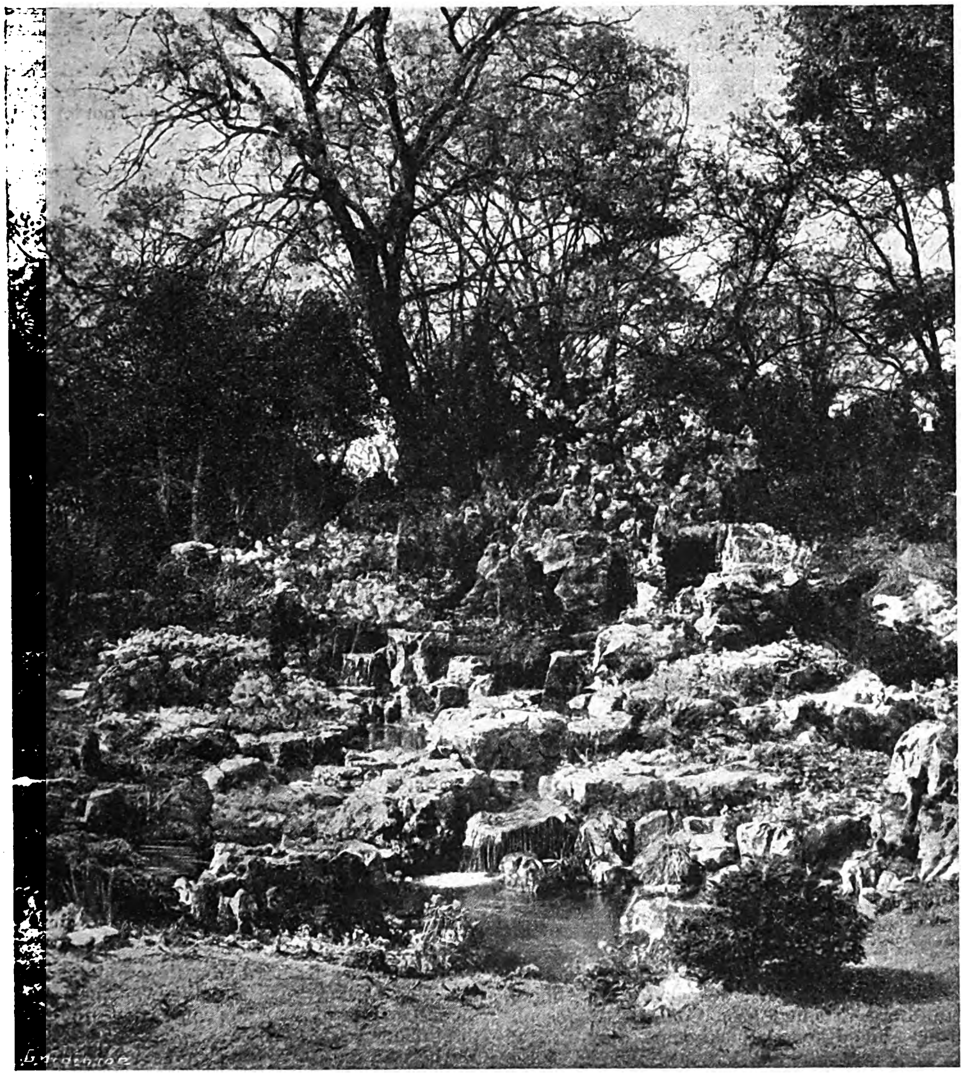

FIG. 209.—CHELSEA SHOW: MR. G. G. WHITELEGG'S ROCK GARDEN.

(see p. 386.)

The Art Tent.

On the lawn a large tent was devoted to paintings of flowers and garden scenes, to photographs and garden plans. To our mind, these were a very mixed assembly. A few were very good, more were moderately good, and others were, well, not so good. We are well aware that the critic of anything designated as art treads a path set densely with thorns, and we seem to have heard something to the effect that "Art is Long and Life is Short." Even now a spirited controversy is being waged in some of our contemporaries as to the artistic merits or otherwise of a certain work in stone. According to some, it seems that a work of this kind which may offend the artistic eye of a section to-day is certain to become the quintessence of things artistic in the near future. The conclusions we draw are that a painting which we to-day consider a daub may be an expression of the highest art in the eyes of a future generation. All this is as may be, but for the moment we prefer to remain old-fashioned and refuse to admire any painting or drawing of garden *genre* when we fail to recognise the subject of at least one of its component parts. When this happens, as it did quite a number of times at Chelsea, we class the paintings as daubs, and regret that the R.H.S. could not devise some system of selection so that, perhaps, fewer paintings, but of real merit should have adequate space for our enjoyment of their beauty.

According to the official catalogue of the show there were over forty exhibits in the Art Tent. Like that given to some of the artists, our space is very limited, so that we can mention only a few of the exhibits which pleased us most of all, and beg those exhibitors who may not be mentioned not to assume that theirs were the paintings which we consider should have been placed elsewhere, for in a number of instances this would be very far from correct.

Last year, when in California, Miss Winifred Walker made many most faithful paintings of native flowers, and her collection was given the Society's Silver-gilt Medal. We are glad to know that, later, we shall have an opportunity of further examining the paintings. For the present we were content to greatly admire the large Spanish pot of various flowers, including Bougainvilleas and Hibiscuses, grown in the gardens of California. Other paintings which delighted us were the truss of Rhododendron, the bowl of rich red Roses, an old-fashioned jug of June flowers, another of cottage-garden flowers, and the bowl of Pansies. Miss Juliet Williams caught and fixed the delicate charm of the elusive Salpiglossis in one of her paintings and had another of the early yellow Jasminum. Miss E. S. Ough had a number of very faithful studies of garden flowers, especially of Roses, Polyanthuses, Oriental Poppies and of gardens. Miss A. F. Wilkinson's gardens also were, to us, real living gardens. The forecourt gardens of Mrs. Russell Walker were pleasant, desirable places. Miss Ethel Willis was especially successful with the single-stemmed Croton and a bowl of Anemone japonica, and Miss E. Savory caught the charm of the stellata Cinerarias and the solid beauty of mixed Zinnias.

There were many woodland scenes, and of these we liked Miss Warrington's Daffodils under the spreading Beech trees and her Rhododendrons by the water-side; and Miss Pilkington's beautiful woodland and her flower borders. Mrs. E. A. Andrews painted life-like Delphiniums, Sweet Williams and Cydonias, and the garden flowers of Mrs. E. Fisher and of Miss Lilian Archer were worthy of more than a passing glance. There were not many studies of still life, but Mr. Leonard Philpot and Miss M. Angell were very successful with their fruit, and the latter also had a charming spray of Lilac. Miss W. M. A. Brook had many valuable paintings and drawings of injurious insects and their hosts.

Garden Sundries.

There seemed to be a greatly increased number of horticultural sundries. On the present occasion these filled the whole of the Sundries Avenue, the available portion of the Main Avenue, Monument Road and spread over a deal of the lawn.

Except for the revolving glasshouse, the glass houses, garden frames and the all-important heating apparatus, were erected in Monument Road. Owing, we understand, to lack of space, the exhibits of garden boilers and piping were not so extensive as usual. Messrs. C. P. Kinnell and Co. had their powerful Bisson and Rochford boilers in brick settings, and also showed their horseshoe and other patterns which are suitable for medium-sized and smaller structures. An interesting novelty to many visitors was their equipment for converting any type of greenhouse boiler into an oil fire to consume a heavy, crude oil. This is of automatic nature and the thermostat controls the flow of oil to the burners.

Messrs. Kinnell and Co. also showed their well-known garden hose and their Norwich valves. The Thames Bank Iron Co. showed boilers well set in brick.

There was a great variety of glasshouses. Messrs. Duncan Tucker, Ltd., had a good range of their glasshouses in Teak-wood, with attendant frames and an attractive garden house. Messrs. Boulton and Paul erected a greenhouse of pleasing design, complete with boiler and piping and frames, and also had a revolving garden shelter. The Battle Steel Window Co. showed a greenhouse and frame and also iron fences and gates. Messrs. James Gray, Ltd., set up a workmanlike greenhouse with heating apparatus and lath blinds. The well-designed greenhouses of Messrs. Messenger and Co. were also fitted with lath blinds, and their Loughborough boiler. A greenhouse, frames and garden furniture, were displayed by Messrs. A. Overend and Sons. Messrs. Skinner, Board and Co. erected one of their wire-tension glasshouses. Messrs. David Swain and Co. had a fine selection of well-designed houses complete with boilers and pipes and also showed garden frames and furniture. Messrs. J. Weeks and Co. had their well-known patterns with heating apparatus and wood lath blinds. Messrs. Wm. Wood and Sons also showed good greenhouses. The greenhouse novelty in Monument Road was the concrete glasshouse erected by Messrs. C. Rawson and Co., which is of pleasing appearance. Except that the glass is set in lead rabbets packed with asbestos, the structure is of concrete and, it is claimed, everlasting.

In the Sundries Avenue several well-known horticultural sundriesmen had very attractive kiosks where they set out a considerable variety of goods. Messrs. G. H. **Richards, Ltd.**, displayed their well-known Xl All preparations, Kamforite, fumigating Shreds, Worm-killer, Vitalizer manure and many more preparations. Messrs. **Corry and Co.** made attractive displays with their Niquas, Weed Death, Lethorion Cones, Summer Cloud, Extract of Quassia, and the old favourite Gishurst Compound. White Fly Compound was given a prominent place by Messrs. **Abol, Ltd.**, who also showed their well-known syringes, Neuspray, White Fly Compound and Weed-killer.

Two large kiosks were filled by Messrs. **George Monro, Ltd.** In one they had the Simar Rototiller and the Monotrac Motor Cultivator, while in the other they displayed almost every possible garden aid in necessity. Messrs. **Murphy and Son** had a good range of fungicides and insecticides. Messrs. **Wakeley Bros. and Co.** had a very attractive stand where they set out samples of their well-known Hop Manure and many other preparations.

The value of the Shoulder Hoe was demonstrated by Mr. **John Hampson**, who showed its easy working and labour-saving qualities. The various accessories fascinated many interested visitors. The **Acme Chemical** Co. showed weed-killers, worm-killers, lawn sand and various insecticides and fertilisers. Messrs. J. **Fison and** Co. had their fish and other manures, with worm and weed-killers.

The **Chase Continuous Cloche** was set out in goodly lengths over various seedling plants. Mr. J. **Haw** had many of his useful watering-cans and garden engines. Messrs. **Prentice Bros., Ltd.**, had attractive tins and cartons of Tomorite and other fertilisers. **Walker's Fruit Tree Protectors** contained fully-grown trees, and they also showed tennis netting. Chief among the many cutting implements was the Rolcut Secateur, which was shown by Mr. B. J. **Walker**, who also had several useful cultivating tools.

Spraying machines were shown in great variety by the **Four Oaks Spraying Co.**, who had their large orchard pattern and knapsack sprayers; Mr. E. H. **Hill**; the **Holder Harriden Co., Ltd.**; Messrs. **Robinson Bros, Ltd.**, who also had watering-cans and fertilisers; and Mr. A. S. **Sedgwick**, who showed his handy little greenhouse sprayer.

There were plenty of lawn-mowers on view, and these included the speedy and powerful motor-driven machines as well as those for horse-power and manual labour. Messrs. **Dennis Bros.** had their special patterns. Messrs. T. **Green and Son** had a great range of motor, horse and hand patterns. The **Godiva Engineering** Co. included lawn markers with their mowers; the easy-running J. P. Super Lawn-mowers were shown in several patterns; the well-known **Atco** pattern was on view in a large stand; Messrs. **Ransomes, Sims and Jefferies** were busy demonstrating the values of their various mowers, as also were Messrs. A. **Shanks and** Co. with their well-known designs.

The chief exhibitors of garden furniture, ornaments and other materials were Messrs. **Abbott Bros.**; the **Acme Patent Ladder** Co., **Castles' Shipbreaking** Co., Messrs. **Drew, Clark and** Co., the **Dryad Works**, Messrs. A. W. **Gamage and** Co., who also showed hammocks and small tents; Messrs. **Robert Green, Ltd.**, Messrs. **Gilliam and** Co., Messrs. **Harrods, Ltd.**, Messrs. **Burton, Holt, Ltd.**, Messrs. **Hughes, Bolckow and** Co., Messrs. R. A. **Lister and** Co, who had attractive plant tubs, Messrs. A. H. **Moorton, Ltd.**, **New Cross Timber** Co., Messrs. **Piggott Bros. and** Co., the **Papworth Industries**, Messrs. **Plant Bros.**, Messrs. **Pulham and Son**, Mr W. T. **Revitt**, Messrs. **Sanders and** Co., Mr. H. C. **Slingsby**, Messrs. **Wakeley Bros. and** Co., and Mr. C. **White**.

Horticultural publications were exhibited extensively and *The Gardeners' Chronicle* kiosk was a rendezvous for many of its readers.

NATIONAL TULIP.

The Annual Show of this Society was held under the auspices of the Royal Horticultural Society, at the Chelsea Flower Show, on May 23 and 24. It was tucked away in a small section of a tent, the exhibits lining about half the wall space, so that there was ample room for the visitors desirous of ascertaining the abilities of this Society to stage a show. In the Royal Horticultural Society's old hall at Vincent Square, it would have been comfortably housed in an annexe; at Chelsea it was swamped and insignificant.

As to the exhibitors, there were six, chief among them, and sharing the honours, being Sir A. **Daniel Hall**, Merton; Mr. W. **Peters**, Cambridge; Mr. C. W. **Needham**, Hale; Mr. **Peter** R. **Barr**, and Mr. A. E. **Amos**, Colchester; these would appear to be the National Tulip Society.

There were ten classes in all. Sir **Daniel Hall** was first in the premier class, for twelve dissimilar rectified Tulips, two feathered and two flamed, with good specimen blooms of and Sir Joseph Paxton, Sir **Daniel Hall** was first for three flamed Tulips; Mr. W. **Peters**, being placed second; Sir **Daniel Hall** was also first for six dissimilar breeder Tulips, with Dorothy Ann, rich red, with a white base; Ducalion, Mary Swan, Lucy Luard, Romeo and Mars, orange-scarlet, yellow at the base, awarded a special prize as the premier Breeder in the show. Mr. P. R. **Barr** was second in this class, and Mr. C. W. **Needham**, third.

Sir **Daniel** was also first for three dissimilar breeder Tulips, with Daphne, Cyrano and Gloriana; Mr. P. R. **Barr** was second, showing Annie McGregor, Adonis and Goldfinder.

Mr. C. W. **Needham** secured the "Samuel Barlow" prize for the best pair of rectified Tulips, one feathered and one flamed, with good blooms of Sir Joseph Paxton and Mrs. Atkin, Sir **Daniel Hall** and Mr. **Peter** R. **Barr**, being second and third respectively.

In the class for six dissimilar rectified Tulips, Mr. A. E. **Amos**, was first with good examples of Duchess of Sutherland Stockport, Mabel, Lucy Luard, Julietta and Britomart, outstanding; Samuel Barlow, Garibaldi, Daphne, Mabel, Lord Stanley, Mrs. Collier, Sir Joseph Paxton and Rhoda Backhouse. Mr. **Peter** R. **Barr** was second, his best blooms being of George Hayward, a grand old favourite, adjudged the best feathered Tulip exhibited; Wedding Coat, James Wilde, a good feathered Bizarre; Duchess of Sutherland, and Mabel. Mr. W. **Peters**, Cambridge, was third, his collection including the premier flamed Tulip shown, a grand bloom of Sam Barlow; Mr. C. W. **Needham** was fourth.

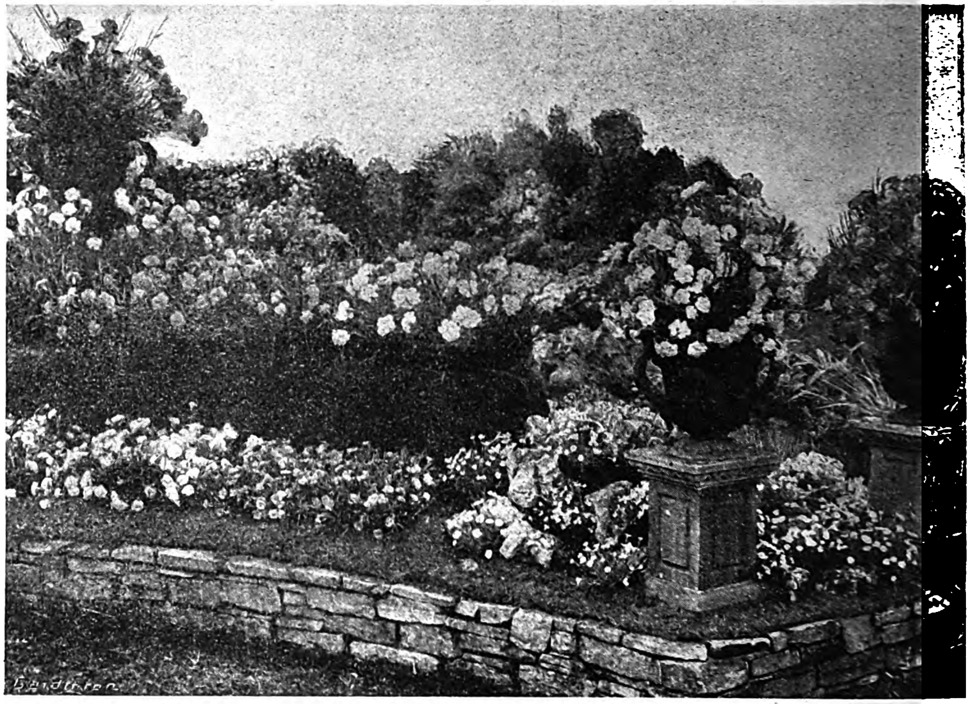

FIG. 210.—CHELSEA SHOW: MESSRS. ALLWOOD BROS.' CARNATIONS AND HYBRID PINKS.

(see p. 388.)

In Class B, for six dissimilar rectified Tulips, one feathered and one flamed of each, Mr. C. W. **Needham** was first; Sir **Daniel Hall**, second; Mr. P. R. **Barr**, third, and Mr. W. **Peters**, fourth. Mr. **Needham's** six blooms were of Mrs. Collier, George Edward, Sir Joseph Paxton, Annie McGregor, Attraction and Bessie.

Mr. C. W. **Needham** was also first for three feathered Tulips, one of each class, his specimen blooms being of William Anniball, yellow, feathered red; Clio, white, with purplish-red feathering; and Annie McGregor, white, feathered red. Mr. W. **Peters** was second, with examples of Jane, Bessie and Robin; and Sir **Daniel Hall** was third.

With good blooms of Cecilia, George Edward Kate Connor, Richard Headley and Adelheit; Mr. E. **Chater**, East Finchley, being placed second. Mr. **Amos** was also first for three dissimilar breeder Tulips, with Adonis, Lord Derby and James Wilde; and for two rectified Tulips, with Lucy Luard and Annie McGregor.

Messrs. **Barr and Sons** had two small exhibits of various old-English Tulips, including some attractive flamed and feathered sorts.

ROYAL CALEDONIAN HORTICULTURAL.

At the monthly meeting of this Society, held at Edinburgh early in May, Mr. J. T. Jeffrey presiding, Sir Everard im Thurn delivered a lecture on "Orchid Collecting by an Amateur." He described his journeyings in British Guiana as far inland as Mount Roraima, which he pictured as the Eldorado of some botanists. The microscopic Orchids which he collected were botanical curiosities, found growing on the branches of trees in swamps and forests where all manner of plants were to be found. Incidentally, he mentioned that Cattleya superba was one of the Orchids of commerce in that country, it being collected by the natives and taken down to the coast and sold.

In the competition for the best Schizanthus, the first prize was awarded to Mr. Bernard McWeeney, Old Farm, Colinton, for a well-grown plant measuring six feet in height, five feet in diameter, and sixteen feet in circumference. Mr. J. A. Sword, Inveralmond, was second, with a fine hybrid of his own raising. Mr. Neil Leyden, Midfield, Lasswade, was successful in the class for two vases of Darwin Tulips, while a Cultural Certificate was awarded to a group of Gardenias exhibited by the City Parks Department, and to a seedling Carnation of a pleasing pink colour, raised by Mr. John Smith, Balgray Gardens, Lockerbie. A vase of Narcissus Red Beacon was exhibited by Messrs. Dickson and Co., and a Camellia was shown by Mr. Morrison, 2, Goff Avenue, Leith, both of whom received votes of thanks.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the Royal Horticultural Society's Hall, on Monday, early in May, Mr. Charles H. Curtis presiding.

Two new members were elected. Three members withdrew the sum of £21 15s. 1d. from their deposit accounts, and the sum of £132 1s. 0d. was passed for payment to the nominees of four deceased members. The sick-pay for the month on the Ordinary side amounted to £111 11s. 6d., and in the State section to £82 19s. 6d. The sum of £28 7s. 0d. was paid in grants to ten members for dental and optical treatment, and several other cases were considered.

Obituary.

Dr. Trabut.—We regret to learn of the death in Algeria, on April 23, of Dr. Trabut, Director of the Algerian Botanical Service. He was also corresponding member of the French Agricultural Academy and Academy of Science. In 1880, Dr. Trabut was appointed Professor of Natural History at the mixed school of Medicine and Pharmacy in Algiers, and immediately, with his colleague and friend, M. Battendier, set about making an exhaustive study of the Algerian flora. This work completed, he proceeded greatly to enrich the economic flora by judicious introductions and hybridisation, and to his enterprise is due the credit for endowing Algerian agriculture with many new forage plants, cereals, Cottons, valuable fruit trees and other subjects. He worked untiringly to overcome the local prejudice against the introduction of certain fruits which have since proved of great economic value, and succeeded in winning the esteem and admiration of all in the colony. His funeral was attended by the Governor of Algeria and many other notable persons, and it is generally felt that it will be long before his place can be adequately filled.

TRADE NOTE.

The older gardeners will remember the Sproughton hoe, invented by the Rev. A. Foster Mellior—of Rose fame—but gardeners of a later generation may not be familar with its virtues. The Sproughton hoe possesses all the good qualities of the Dutch hoe, with two distinct advantages over that useful soil-tiller; it cuts both ways, fore and aft, so that weeds are never pushed into the soil by it; and as it has a crank-shaped neck, it is entirely open on one side and therefore may be worked quite close up to and around Roses and other plants, consequently it is additionally effective. The larger-sized form has also a knife-shaped point which further increases its value as a weapon of offence against weeds. For surface tillage the larger size will serve for the wider garden spaces, while the smaller will prove satisfactory in the rock garden and among seedlings. Each has a shaft into which a wooden handle may be thrust, as in the case of other hoes, rakes, etc., but we have found the small size extremely useful without this addition, when working in a small but closely-planted area. Messrs. F. Davidson and Co., 143-149, Great Portland Street, are offering these hoes, and also a new type of spud for eradicating fruit tree and Rose suckers; and a weather glass of the old-fashioned Dutch "tea-pot" type, which, when properly supplied with water, gives early indication of weather changes.

ANSWERS TO CORRESPONDENTS.

Cyclamens Failing.—*E. M.* The Cyclamen corm and roots were infested with parasitic eelworms. The soil in which your plants are growing should be sterilised with steam at 180°F. for three hours. For sterilising the small quantity required for your purpose, the pots and soil should be stood on bricks in a copper with sufficient water to cover the bricks. Prolonged baking of the soil in an oven will kill eelworms, but the effect on the soil is less satisfactory.

Cyclamens Attacked by Thrips.—*Bath.* The Cyclamen foliage sent shows the typical symptom of an attack by thrips. Affected plants should be dipped in a Nicotine-soap wash. Daily forceful syringings with clear water will tend to reduce the attack. Fumigation with Nicotine vapour is less efficient for this pest than hydrocyanic acid gas.

Indian Azaleas.—*A. H. R.* The many varieties of Indian Azaleas are best repotted when they have finished flowering and are starting into fresh growth. The compost should consist of good fibrous peat, with enough sand added to keep the whole open and porous; this will depend on the amount of sand originally in the peat. Firm potting is essential. After repotting, the plants require to be kept close and moist, in an average temperature of 55°, spraying several times a day during bright weather, the object being to encourage growth and root action. As the season advances and growth is completed they should be gradually given more air, to harden the growths preparatory to standing them out-of-doors towards the end of June, or even earlier, if growth is completed, the pots being partially plunged in a bed of ashes, which serves the double purpose of conserving the root moisture and preventing the plants blowing over. They should be housed again about the middle of September.

Names of Plants.—*T. J. S.* Cerasus James H. Veitch of nurseries; Prunus serrulata var. Fugenzo, of Japan. *Surrey.* 1, The Narcissus is a Barrii variety, but we cannot undertake to name florists' flowers; 2, Spiraea Thunbergii.—*F. B.* Evidently a garden variety of the St. Brigid type of Anemone. *S. P. S.* A form of Prunus persica.—*P. D.* 1, Pteris tremula; 2, Adiantum cuneatum; 3, Pteris cretica var. major; 4, Asparagus crispus (flexuosa); 5, Pteris serrulata var. cristata; 6, Ophiopogon Jaburan; 7, Asplenium bulbiferum; 8, Linaria Cymbalaria var. variegata.

Tomato and Melon Plants.—*G. S.* The Tomato plants are free from infection by pathogenic organisms, but are affected with "blindness." The stock from which the seeds were obtained has deteriorated. In such cases, a certain percentage of the plants do not produce flower trusses. All plants showing "blindness" should be burnt. The stem of the Melon plant submitted did not afford sufficient material from which to make a diagnosis of the trouble. Send a whole plant.

Tulips Diseased.—*P. C. C.* and *P. P.* The Tulips are infected with "fire," due to Botrytis tulipae. Collect and burn all infected foliage and lift all bulbs after flowering, discarding all those which show any signs of rot and those with black sclerotia on the outside of the bulb. Do not replant in infected soil for at least two years. Protect the plants from cold winds and late spring frosts.

Printed copies of the full Published Specifications may be obtained from the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform price of 1s. each.

Abstract Published.

A new powder fertiliser with the unfailing base of slaked lime has been patented by a German inventor, Mr. F. Boerner, of 69, Hofchenstrasse, Breslau, Grmany, under No. 308,328. Three parts of dry ground slaked lime are intimately mixed with one part of finely ground and calcined infusorial silica or of silicic acid powder, either the silica before mixing, or the resultant mixture, being saturated first with formaldehyde solution and, after drying, with carbon bisulphide. Saturation may be effected by sprinkling devices carried by an endless travelling band. The strength of the formaldehyde solution may be forty per cent. by volume. The preparation may be dusted on to seeds of corn or vegetables, or may be mixed with three or four times its weight of screened house or street refuse to produce, after storage, a combined fertilising and vermin and disease destroying agent. Compost heaps may be treated for the destruction of parasites.

Remarks.—Owing to the improved weather conditions, supplies of cut flowers have become considerably more plentiful, and prices are mostly on the down grade. Tulips are now finishing, also Narcissus poeticus. Double white Narcissi have been arriving from all sources in excellent condition. Coloured Pyrethrums made their first appearance last week-end, while Cornflowers, Delphiniums, Paeonies and Gladioli should become more plentiful during this week. Many boxes of Spanish Irises had been affected by warm weather when they were offered for sale. Sweet Peas are in the best condition received this season, some of the blooms being exceptionally fine in quality, and prices range from 6d. to 2s. 6d. per bunch. Gypsophila elegans and Statice Suworowii are now arriving from home-growers in good condition. Carnations and Roses are again on the down grade, also Lilium longiflorum. Several boxes of yellow Arums (Richardias) have been on sale during the past week. More Stephanotis and Gardenias have been on offer, also outdoor Lily-of-the-Valley. In the foliage department, Smilax has returned to a more normal price. Supplies of Asparagus plumosus and A. Sprengeri exceed present requirements. Maidenhair Fern continues somewhat limited in quantity.

Remarks.— Trade in Covent Garden has, on the whole, been good, the position being largely influenced by the fine weather. There has been an improved demand for Grapes, Strawberries and Melons, which constitute the leading lines of the choice fruit department. Grapes from South Africa and the Argentine are selling well, although prices are inclined to be easier. France is sending supplies of Cherries and Strawberries which are selling fairly well, and some Apricots are arriving from Spain. Pears from Australia and New Zealand are in keen demand at firm prices, and there is quite a good tone ruling in the Australian Apple market. Oranges, Lemons and Grape Fruits are all favourably affected by the warm weather, and are moving out freely. After a period of severe depression, the market for English Asparagus has shown some recovery, and prices have improved slightly. Tomato supplies are rather below requirements and they remain a firm trade; Cucumbers also are selling well at values higher than recent levels. Forced Beans are more plentiful from all sources, and although values have declined, they may still be considered favourable to the producer. Some English Gooseberries from the west of England are arriving and meeting a good market. Hothouse Peas are being enquired for; some English produce is selling well, in spite of comparatively large arrivals from the south of France. New Potatos from Spain are selling well, although prices are rather low, which also affects values of new Potatos from Jersey and Guernsey. Mushrooms are abundant and cheaper. Salads are a firm trade and Lettuces, in particular, are making good prices. Green vegetables and old Potatos are not selling very freely.

GLASGOW.

The excessive heat of the past week had an injurious effect on all cut blooms from the south and as the supplies were beyond the purchasing power of the trade, prices declined sharply to the lowest levels of the spring flowering season. Tulips were badly affected by the weather and Clara Butt, Bartigon and Baronne Tonnaye were only worth 1d. to 3d. per bunch of 12's. A considerable proportion of the Rose blooms were either soft or blown and ranged from 1s. to 2s. per dozen, while Carnations, which suffered less in transit, sold at 1s. to 2s. 6d., with specials at 3s. Pheasant Eye Narcissi ranged from ½d. to 1½d. per bunch; Irises, 10d. to 1s. 6d. per dozen; Anemones, 2s. to 6s.; Arums and Lilium longiflorum, 2s. to 2s. 6d.; Lily-of-the-Valley (outside grown), 4d. to 6d.; and Sweet Peas, 4d. to 10d., special 1s. 6d.

The principal movements in the fruit market were as follows:—Grapes, English Black Hamburg, 3s. 6d. per lb.; South African, black, 17s. per box; white, 12s. to 16s.; Pineapples, 3s. 6d. to 4s. each; New Zealand Apples (Jonathan), 16s. per case; Pears, 6s. per tray. Oranges and Grape Fruits were steady at former quotations.

In the vegetable section, Scotch Tomatos made 1s. 5d. per lb.; Guernsey, 13s. to 14s. per 12 lb. package; Asparagus, 2s. 6d. to 3s. per bundle for English, and 1s. for French; Cucumbers, 7s. per dozen; Lettuces, 8s. (Dutch, 30's); Cauliflowers, 6s.; and Mushrooms, 2s. 6d. per lb.

SCHEDULES RECEIVED.

Colchester Rose and Horticultural Society.—Summer Show, in The Castle Park, Colchester, on Wednesday, June 26, 1929.—Secretary, Mr. A. E. Warner, 60, Head Street, Colchester.

Peterborough Agricultural Society. — Summer Show, on the Show Ground, Peterborough, on Tuesday, Wednesday and Thursday, July 2, 3 and 4, 1929.—Secretary, Mr. Robert Bibby, Agricultural Offices, Cross Street, Peterborough.

Liverpool Horticultural Association.—Summer Show, at the Corn Market, Brunswick Street, Liverpool, on Wednesday and Thursday, July 17 and 18, 1929.—Secretary, Mr. W. D. Skinner, Brooklands, Waterloo Park, Waterloo.

Cheltenham Chamber of Commerce.—Cheltenham Spa Floral Fete in Montpellier Gardens, on Wednesday and Thursday, June 19 and 20, 1929.—Secretary, Mr. Cyril Cassidy, 58, High Street, Cheltenham.

The British Delphinium Society.—First Summer Show, at the Royal Horticultural Society's New Hall, on Friday. July 5, 1929.—Secretary, Mr. S. Halford Roberts, 3, Warwick Road, Thornton Heath, Surrey.

Birmingham Horticultural Society.—Floral Fete and Exhibition, in Handsworth Park, on Friday and Saturday, July 19 and 20, 1929.—Secretary, Mr. L. W. Webster, The Oaklands, 130, Albert, Road, Stechford, Birmingham.

Watford and Home Counties Horticultural Society.—Annual Summer Show, at Cassiobury Park, Watford, on Tuesday and Wednesday, July 23 and 24, 1929.—Secretary, Mr. A. J. Copeland, 132, High Street, Watford.

Hemel Hempstead Horticultural Society.—Summer Show, in The Bury Meadow, on Saturday, August 17, 1929.—Secretary, Mr. E. Edwards, Bargrove Gardens, Boxmoor.

Charfield Fete and Flower Show.—At Charfield, on Saturday, August 17, 1929.—Secretary, Mr. S. Benson, F.R.H.S., The Nursery, Charfield.

British Gladiolus Society.—National Exhibition, at the Royal Horticultural Society's Hall, on Tuesday, August 13, 1929. International Exhibition at Southport, on Wednesday, Thursday and Friday, August 28, 29 and 30, 1929.—Secretary, Mr. A. E. Amos, 10, Bergholt Road, Colchester.

Derby Horticultural Association.—Chrysanthemum Show, in the Royal Drill Hall, on Thursday, Friday and Saturday, November 7, 8 and 9, 1929.—Secretary, Mr. W. Wardman, 5, St. Augustine Street, Derby.

Buxton and District Chrysanthemum Society.—Twenty-fourth Annual Exhibition, in the Pavilion Gardens, Buxton, on Wednesday, November 13, 1929.—Secretary, Mr. A. Nevill, Thornwood Cottage, Carlisle Road, Buxton.

Gainsborough Chrysanthemum Society.—Thirty-second Annual Exhibition, in the Town Hall, Gainsborough, on Wednesday and Thursday, November 13 and 14, 1929.—Secretaries, Mr. H. L. Rowntree, Windy Ridge, Hawthorne Avenue, Gainsborough, and Mr. T. E. Henson, 27, Forster Street, Gainsborough.

GARDENING APPOINTMENT.

Mr. George William Hill, for the past two months gardener to Mrs. Allfrey, Farley Castle, near Reading, and previously for two-and-a-half years Inside Foreman at Sherfield Manor, Basingstoke, as gardener to Lieut.-Col. Thomas Brocklehurst Phillips, O.B.E., J.P., at Cherry Hinton Hall, Cambridge. [Thanks for 2s. for R.G.O.F. Box.—Eds.].

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 58·4°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, June 5, 10 a.m. (Greenwich time). Bar. 29.8. Temp. 54°. Weather, dull and cool.

The History of the R.H.S. Fruit Committee.

THE Committees of the Royal Horticultural Society charged with the duty of valuing the exhibits placed before the Society are now so well established that it will come as a surprise to many to know that some fifty years elapsed before the Council found itself unable to continue this work and delegated the task to bodies of specialists. In the early days of the Society, fruits and vegetables held a much more commanding position than they now do; these were the days of the utilitarian philosophers. The first "meetings" we read of were dinners, and the dates were specially chosen so that the dessert might be representative of the best that horticulture could provide. As the Society grew in numbers, breakfasts were substituted at the famous Chiswick and Kensington shows. It was not until the year 1858 that the proposal of a special Fruit Committee came to fruition, and at the Anniversary Meeting in May of that year, Dr. Lindley read a report, in which occurs the following: "It is therefore proposed at once to form a Committee for the examination of all new fruits; another may perhaps be charged with deciding the merits of florists' flowers, and so on." The first meeting of the Fruit Committee took place on November 6 of the same year, and it is interesting to read the names of the first members: Chairman, Rev. L. V. Harcourt; Deputy Chairman, Mr. Charles Edmonds; Secretary, Mr. Robert Thompson; Messrs. Hy. Bailey, H. G. Bohn, M. Busby, Rev. A. Clive, John Clutton, J. Duncan, G. Fleming, R. G. Foggo, James Forbes, J. Fraser, J. B. Clegg, A. Henderson, R. Hogg, Thos. Ingram, John Lee, J. D. Llewellyn, Thomas Moore, Robert Osborne, Thomas Rivers, R. Smith, R. Sneyd, Lewis Solomon, John Spencer, C. W. Strickland, T. Taylor, W. Tillery, G. Tillyard, James Veitch, junr., and J. B. Whiting. It will be seen that many members were nurserymen famous in their day, and among the amateurs we note Mr. H. G. Bohn, the famous bookseller and publisher, one of the pioneers of the cheap classics. A great many of the names are those of members of the British Pomological Society which was established in 1854 under the Presidency of Sir Joseph Paxton, and of which Robert Hogg was one of the Secretaries. The new Fruit Committee was probably inspired by the older Pomological Society, which continued to meet until 1860, when, apparently, it came to an end. Mr. E. A. Bunyard has a copy of the *Proceedings*, which previously belonged to Robert Hogg, but they cease at 1860. The objects of the Fruit Committee were laid down by the Council as follows:—"The objects to which the attention of the Fruit Committee of the Horticultural Society will be principally directed are these:—(1), To encourage the production of new and improved varieties of fruits and vegetables, by examining and reporting on such as may be submitted to them for the purpose; (2), to collect and disseminate reliable information respecting the adaptability of particular kinds of fruits to the varied conditions of soil, locality, etc. throughout the United Kingdom, by means of a series of inquiries and examinations hereinafter to be defined." Since its establishment, the Fruit Committee has been mainly occupied in reporting upon new fruits and recommending awards to exhibits, but it has initiated enquiries into the subjects named in section two of its reference and the publication of *A Selected List of Hardy Fruits* was due to its efforts. In looking back on the eminent men who have occupied the chair and vice chair, we see that from 1866 Mr. G. F. Wilson, of Wisley fame, and Mr. A. Smee, F.R.S., and Mr. H. Webb, of Redhill, worthily filled these posts; Mr. Smee is remembered by his popular book *My Garden*. From 1880 and onwards, Sir Harry Veitch, Mr. John Lee, Mr. F. T. Rivers, Dr. Hogg, and Mr. Philip Crowley, and from 1900, Mr. George Bunyard, V.M.H., and Mr. C. G. A. Nix, V.M.H., occupied the chair with general approval. The relations of the Fruit Committee with the Council have been, it seems, mainly of a cordial nature, although present members will remember one instance in which temperatures rose slightly above the normal, but the cause of offence was quickly removed and amity resumed her wonted place. Of the vast numbers of new fruits which have passed before the Committee, how many have fulfilled their youthful promise? A glance at the list of awards enables a very rough answer to be given to this question and against those few lost or forgotten "First Class" Certificated varieties can be set many of outstanding merit which survive to this day. The great number of first-class fruits which came from the houses of Rivers, Laxton and others were in most cases recognised at once for what they were. Did the Committee, we wonder, realise that when they saw a large cooking Apple on December 6, 1876, from Mr. Merryweather, and awarded it a "Highly Commended" Certificate, that they were acknowledging in the now well-known Bramley's Seedling a cooking Apple which in fifty years would be among the most popular of English fruits? One function which the Committee has undertaken, namely, the identification of fruits, has always been performed under great difficulties. Pressure of time, and lack of reference books or specimens, has very seriously handicapped the execution of this always difficult task. It is still not generally realised that for accurate naming of fruit all the available facts must be considered. The age of the tree, the foliage, and conditions of growth, are necessary as well as the fruit, which is only one of the factors. Thanks to the recent provision of a fruit room in the new hall, the presence of a herbarium now in process of formation, and a collection of works of reference for their special use, the Fruit Committee should now be able to undertake this onerous duty under better conditions. It rests with the enquirers to see that their side of the contract, namely, full provision of data and adequate specimens, is adequately fulfilled. It is a peculiar privilege of members of the Royal Horticultural Society that they can obtain without cost the opinion of the best-known experts, and among those who give so generously of their knowledge the members of the Fruit Committee are specially notable. No other Committee stays on after its normal business to name specimens in anything like so large an amount, and for this work alone the Fruit Committee should obtain a very special measure of gratitude from all interested in horticulture.

Our Coloured Supplement Plate.—As Irises will be claiming the interest of many of our readers during the next week or so, we have pleasure in presenting with this issue a reproduction, in colour, of the beautiful Iris Bruno, which is dealt with at length under the heading "Irises of the Bruno Type," on p. 427. The blooms depicted were exhibited by Mr. G. L. Pilkington at last year's Iris Show.

The King's Birthday Honours.—The list of rewards for public services conferred by His Majesty the King on the occasion of his sixty-fourth birthday contains few names of special interest to horticulturists and agriculturists. Sir Robert A. Sanders, Minister of Agriculture and Fisheries in 1922-24, becomes a Baron. The Zoological Society's Gardens at Regent's Park have always been noted for their good gardening as well as for the fine collection of animals, therefore we are glad to find that Mr. Peter Chalmers Mitchell, Secretary of the Society, becomes a Knight. Mr. Ernest William Davy, Assistant Director of Agriculture, Nyassaland Protectorate, receives the M.B.E., and Mr. John C. F. Fryer, well-known for his research work at the Pathological Laboratory, Harpenden, receives the distinction of O.B.E., while Mr. Francis J. Plyman, Director of Agriculture, Central Provinces, India, becomes a Companion of the Order of the Indian Empire.

Captain F. Kingdon Ward.—No further news has been received regarding Captain F. Kingdon Ward, who is seriously ill at Moung-Sing, in western Tonkin. Mrs. Ward proposes to leave London by air mail for Karachi, on Saturday, June 8, *en route* for Moung-Sing, to nurse her husband, to whom medical assistance has been despatched from the Shan States.

The Marking of Imported Rose Trees.—Under an Order in Council, and in pursuance of Section 7 of the Merchandise Marks Act, 1926, it shall not be lawful to sell or expose for sale in the United Kingdom any imported Rose trees unless they bear an indication of origin. The indication of origin shall be legibly and durably marked in a conspicuous manner, either:—(1) on a metal or wooden label securely attached by wire or other metal fastening to the collar of each Rose tree, or (2) on a metal band clasped around the collar of each Rose tree. "The provisions of this Order shall not extend to Rose stocks. This Order shall apply on exposure for sale wholesale whether the person exposing the goods is or is not a wholesale dealer. The provisions of this Order shall come into force at the expiration of three months from the date hereof." The Order is dated May 7, 1929, and is No. 395 of Statutory Rules and Orders, 1929.

French Pomological Society.—The sixty-fifth session of the French Pomological Society will take place from September 19 to 23, at Clermont-Ferrand, under the auspices of the Puy-de-Dome Horticultural Society. The Conference, at which many interesting questions will be discussed, will occupy the first few days of the session, but the 22nd and 23rd will be devoted to excursions to places of interest in the vicinity, including Glozel, where so many prehistoric remains of doubtful authenticity were recently unearthed.

Importation of Cherries.—With the object of preventing the introduction of the Cherry fruit fly, the Minister of Agriculture and Fisheries has made an Order under the Destructive Insects and Pests Acts, 1877 to 1927, regulating the importation of Cherries into England and Wales during the 1929 season. Cherries grown in France will be admitted without restrictions until June 15, after which date those grown in the southern zone will be prohibited. This zone consists of seventeen departments, including the whole of the Departments of Ardèche and Drôme. Cherries from the central zone (twenty-one departments) will be admitted until June 20, and those grown in the northern departments until July 6, after which date the importation of French Cherries will be prohibited, except of those grown within a small district around Honfleur, details of which appear in the Order. Cherries grown in Italy will be admitted without restrictions until June 10, after which date those grown in the region of Apulia will be prohibited; after June 20, this prohibition will extend to Cherries grown in the regions of Basilicata, Calabria and Campania; after June 30, the importation of Cherries grown in any part of Italy will be entirely prohibited. Certificates of origin must accompany Cherries grown in any other European country which are imported after June 15. Copies of the Order may be obtained on application to the Ministry.

British Mycological Society.—The Annual Phytopathological Excursion will take place on June 8, at the Royal Horticultural Society's Gardens, Wisley. Members will meet at the entrance to the Gardens at 11.30 a.m., and should bring lunch. Tea will be provided. Routes :—By train from Waterloo (9.40 a.m.) to Kingston, thence by bus No. 115 (10.30 a.m.), or No. 620 (10.20 a.m.). Book to the Hut Hotel. Alternatively by road from Byfleet or Effingham Junction, a walk of about three-and-a-half miles in each case; trains, Waterloo, 9.24 a.m., arrive Byfleet, 10.13 a.m.; Waterloo, 9.45 a.m., arrive Effingham 10.21 a.m.

Aldenham House Gardens.—By kind permission of the Hon. Vicary Gibbs, the gardens of Aldenham House will be open to the public on the Saturdays of July, August and September, and on August Bank Holiday, on the same conditions as before :—(a) that dogs cannot be admitted, and (b) that children must be under the control of a grown-up person. One Saturday, July 20, is excepted, this being the date allotted to the Elstree and District Horticultural Society for its Floral Fête, when admission will be only by payment of the Society's charges at the gates, or by ticket.

Dublin Park Gardeners.—The gardeners employed in the public gardens of Dublin (Phoenix Park, St. Stephen's Green and the Botanic Gardens) have lately been agitating through the Civil Service Representative Council for paid annual leave, which up to the present they have not enjoyed. The agitation has now, however, been successful, and the Irish Free State Government is prepared to approve of the granting of six days' annual leave with pay to gardeners and garden labourers with two years' service, on the condition that no expense is incurred in providing substitute labour. It is understood that this latter condition can be fulfilled by an arrangement with the office of Public Works.

Mr. F. R. Petherbridge, M.A.—Among the several research workers who have devoted special attention to soils in glasshouses and the investigation of pests and diseases of fruit crops, Mr. F. R. Petherbridge, M.A. (Natural Science Tripos, Cantab., and Diploma of Agriculture, Cantab.), is one of the most brilliant. During 1910-12, he worked at the Rothamsted Experimental Station in collaboration with Sir John Russell on the sterilisation of glasshouse soils and the cause of "sickness" in glasshouse soils, and the results of these investigations appeared in the *Journal* of the Ministry of Agriculture and the *Journal of Agricultural Science*. It was in 1912 that Mr. Petherbridge accepted the post of Biological Adviser to the Eastern Counties Province at the School of Agriculture, Cambridge, and he still retains that position. His work entails the giving of advice on pest control to growers, mainly in conjunction with county officers, and the carrying out of research work regarding the control of the more important pests of agriculture and horticulture in the area. In conjunction with Mr. J. C. F. Fryer, of the Ministry of Agriculture, and Mr. M. A. Husain, he has worked out detailed life histories of the capsid bugs on Apple trees, and carried out numerous experiments on the control of the Apple capsid bug (Plesiocoris rugicollis); these experiments show that the time and method of spraying are very important. In conjunction with Mr. Thorpe, he has worked out the life history of the common green capsid bug (Lygus pabulinus) which is now a serious pest on Currants, Gooseberries, Strawberries, Dahlias and many other crops. In conjunction with Mr. Tunnington, he found how the Apple sawfly can be controlled (*Journ.* Min. Agric., Feb., 1929), while in 1913-15 he worked on the American Gooseberry mildew to show that this disease could be controlled on a commercial scale by spraying with lime-sulphur, and that tipping was of little commercial value. More recently he has demonstrated the capabilities and limitations of tar distillate washes. Mr. Petherbridge's observations on Silver Leaf disease over a number of years have shown that cutting out diseased parts of Plum and other trees at the right time is a very important factor in its control. Some of his experiments on Potato blight were published in the *Journal* of the Ministry of Agriculture in January, 1919, and June, 1920. He has also worked out the life history of the Strawberry tortrix, which caused a great deal of damage in the Wisbech area some years ago, and in conjunction with Mr. H. W. Miles has conducted experiments in the control of wireworm, more especially in glasshouses (*Journ.* Min. Agric., Jan., 1929, *Annals of Applied Biology*, Aug., 1927). Another useful investigation was the working out of the life history of the Turnip mud beetle and the best means of reducing the damage it causes, and last year Mr. Petherbridge found that naphthalene gave an extraordinary good control of the Cabbage-root fly. Mr. Petherbridge is the author or joint author of many papers that have appeared in the *Journal* of the Ministry of Agriculture, *Annals of Applied Biology*, and other publications, and his versatility is shown by the fact that he has dealt with the pests and diseases of Wheat and the fauna and flora of flooded fenland, in addition to the troubles that vex Potatos, Strawberries, Apples and Plums, and the investigation of soils.

MR. F. R. PETHERBRIDGE, M.A.

Rose Rust.—Mr. Courtney Page, Hon. Secretary, National Rose Society, 28, Victoria Street, S.W.1, is anxious to collect as much data as possible concerning the disease known as Rose Rust that is becoming rather prevalent among Roses. It usually makes its appearance about the end of June and attacks the Rose foliage on the underside. It may easily be identified by its browny-red and black sooty spots, which have the effect of causing the leaf to die and fall. Mr. Courtney Page will be glad if any of our readers who may have plants attacked with the disease during the summer, would be good enough to send him specimen leaves. It would be very helpful, too, if they would state, if possible, the stock on which the Rose is budded, or where the plants were obtained.

Flowering Plants of South Africa.—Part 32, Vol. VIII, October, 1928, of *The Flowering Plants of South Africa*, recently issued, contains admirable coloured plates, and descriptions of Leucospermum glabrum (t. 311), Corycium tricuspidatum (t. 312), Eulophia caffra (t. 313), Buddleia auriculata var. euryifolia (t. 314), Aloe longistyla (t. 315), Disperis Cooperi (t. 316), Ixia monadelpha (t.317), Cyanotis lapidosus (t. 318), Eulophia fragrans (t. 319), and Streptanthera cuprea (t. 320). These are all indigenous to South Africa, as, indeed, are all the plants which appear in this extensive work, which is edited by Dr. J. B. Pole Evans, C.M.G., F.L.S., and is published in this country by T. Reeve and Co., Ltd., Bank Street, Ashford, Kent. The work is issued in parts every three months, the annual subscription being £3; Vols. I to VIII, complete, may be had at £3 6s. each (in cloth). Leucospermum glabrum, the first plant figured in Part 32, a member of the Natural Order Proteaceae, and found in Cape Colony, is a comparatively rare species, being, apparently, confined to the George and Knysna districts, where it was collected by Burchell and Bowie over one hundred years ago. Corycium tricuspidatum (Orchidaceae), is of botanical interest, but of little decorative value. On the other hand, Eulophia caffra, belonging to the tribe Vandeae of the Natural Order Orchidaceae, would appear to be decorative as well as very interesting botanically. Buddleia auriculata var. euryfolia is described as a graceful shrub, attaining a height of seven feet, with slightly drooping branches, and cymose inflorescences of cream-coloured flowers, with red-tinted corolla tubes, and with the characteristic, but not so pungent, scent of B. salvifolia. This variety occurs near Barberton and Lydenburg, in the Transvaal, and is also found in Natal and Griqualand East. At Waterval Boorn, Transvaal, it was collected "growing in very moist places between boulders below the waterfall"; in this country B. auriculata var. euryfolia should make an attractive conservatory plant. Aloe longistyla is found in the south-eastern and central part of the Cape Province; the reddish-orange flowers, produced on a stout stem, have conspicuously long filaments and styles. The large-hooded flowers of Disperis Cooperi are rosy-lilac in colour, and are produced in an erect raceme. Belonging to the Natural Order Orchidaceae, it bears the name of its discoverer, Thomas

Cooper, who found it more than sixty years ago near Nelson's Kop, at the summit of the Drakensburg. Ixia monadelpha is an attractive species, its flowers, borne in spikes of eight, being cadmium-orange in colour, with dark blotches at the throat, although, apparently, it has various colour forms. Cyanotis lapidosus is an attractive little Commelina-like plant of prostrate habit, growing naturally in dense masses in crevices of cliffs; it has reddish, succulent stems, and semi-succulent leaves, reddish on the undersides, the pink flowers having light blue, feathered stamens. Eulophia fragrans has cream-coloured flowers of no special charm, produced in a dense raceme, while Streptanthera cuprea is a charming member of the Natural Order Iridaceae, very close to Ixia; the corolla lobes are described as bittersweet-pink in colour, and they have each two dark spots at the base.

"The Scottish Forestry Journal."—This Journal is the official organ of the Royal Scottish Arboricultural Society, members of which will welcome the recent publication of Part I, Vol. 43 (March, 1929), which contains much information of value to foresters. Sir Hugh Shaw Stewart, Bart., writes on the "Various Aspects of Sitka Spruce on Ardgowan Estate, and various deductions arrived at." The deductions are of economical interest, and the conclusion arrived at by Sir Hugh Shaw Stewart is that it is not good policy to plant Sitka Spruce pure, but to plant it, if the ground is suitable, alternately with Japanese Larch at five-and-a-half feet apart each way; if the ground is too wet for Japanese Larch the Common Spruce should be substituted, although this latter must be regarded as second best. The Douglas Fir Adelges, the aphis responsible for the Christmas-tree effect taken on by Douglas Firs, is dealt with by Mr. Frederick Laing, of the British Museum (Natural History), and Mr. John T. Smith writes on "The Home Timber Trade and the Derating Scheme." One of the most valuable articles in this interesting journal is that by Mr. R. Cowell-Smith, on "Turf-planting: Its Practical Uses and Possibilities," while another of special interest to the student of silviculture is "The Soil and the Forest: Soil Classification and Description," by Mr. George K. Fraser; a lengthy and comprehensive treatise. Professor A. W. Borthwick, D.Sc., suggests that, through the medium of *The Scottish Forestry Journal*, facts concerning the many old and remarkable trees in Scotland be placed on record; Dr. Ernest V. Laing, discourses on "The Living Tree," and Mr. P. Murray Thomson contributes an interesting article on the "Utilisation of Colliery Pit-banks." The latter part of the publication is devoted to reviews of books associated with silviculture, and a Report on the activities of the Society. The journal is well printed, and several of the articles are excellently illustrated, the whole reflecting great credit on those responsible for its production.

Destruction of the White Fly by Parasites.—Many people who have greenhouses find their plants troubled with this pest. There are several methods of dealing with it; the latest is that of killing it by means of parasites. The Empire Marketing Board and the Ministry of Agriculture, acting with the Experimental Research Station at Cheshunt, in Hertfordshire, have arranged a plan for the distribution of a parasite which lays its eggs within the scales or egg-houses of this fly and thus destroys the pest in its young state. This parasite is entirely harmless to plants; indeed, it is dependent on the White Fly for its existence, and, although the method is slow, it is very sure. The parasite is known as the chalcid wasp, and the Research Station at Cheshunt will, so far as they can, supply it to owners of glass-houses and conservatories. Owners should write to the Entomologist of the Station, Cheshunt, Herts, for information concerning the distribution of this parasite.

Appointments for the Ensuing Week.—Tuesday, June 11: Royal Horticultural Society's Committees meet (two days); Jersey Gardeners' Society's meeting. Wednesday, June 12: Sussex County Agricultural Society's Exhibition (two days); Sheffield Chrysanthemum Society's lecture. Friday, June 14: Royal Horticultural and Arboricultural Society of Ireland's meeting. Saturday, June 15: Leeds Paxton Society's Viola Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Kew Gardens.*—We have before us Sir William Hooker's last report on Kew Gardens, dated April 5, 1854. It tells us that the visitors have increased from 9,174 in 1841 (he might have said from 0, or some undiscoverable number in 1831) to 331,210 in 1853; and he points with just pride to the Museum there, almost the work of his own hands, compared with which the botanical part of the British Museum is contemptible. "In less than seven years from its foundation a collection is formed, at almost no expense to the country, mainly from donations, such as no other country possesses and such, we may truly say, as no other country has attempted to form, notwithstanding its manifest advantages to a great commercial nation." The Director also announces the donation to the Museum of the books and herbarium of the late Dr. Bromfield, and the far more important collection formed by Mr. Bentham, a noble gift, for it is the second herbarium in this country, and one of the finest in existence. Such are among the early results of a system of management of which all must approve; and at what cost is this effected? It will be found from the estimates that all which Kew asks for this year is £11,000, less than two-thirds of what the St. James', Green and Hyde Parks require. And this, we presume, includes the cost of botanical lectures which it is in the contemplation of the chief commissioner to have delivered during the summer. Lectures explanatory of the application to practical purposes of the vast riches gathered together at Kew, were all that remained to render the establishment a perfect machine for public instruction. If, as we take for granted, these are to be entrusted to Dr. Hooker, we know enough to be certain that they will not only add much to the value and popularity of Kew Gardens, but greatly raise the establishment in the eyes of the scientific world. Such is a rapid sketch of the result of a fair inquiry into notorious abuses, when entrusted to independent, resolute and competent men. Might not similar advantages be derived from such an examination into the Royal Forests? *Gard. Chron., June* 10, 1854.

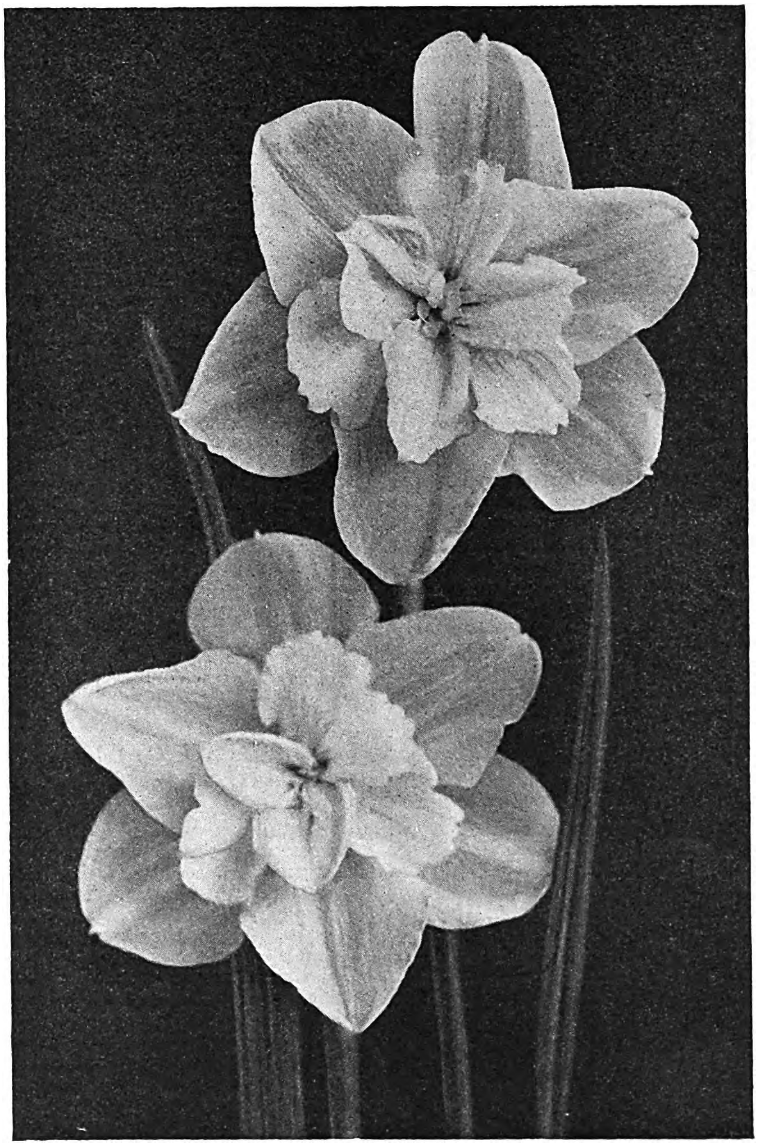

FIG. 211.—NARCISSUS TRIPLEX.
R.H.S. Award of Merit, Chelsea Show, May 21. Flowers pure white.

Publication Received.—*Spanish Gardens*, by Mrs. Patrick Villiers-Stuart; royal octavo, cloth, gilt, pp. 139, with eighty-six full-page plates (six in colour) and numerous illustrations in the text. Messrs. B. T. Batsford, Ltd., 94, High Holborn, E.C.; price 25s. net,

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Treatment of Imported Orchids.—Opportunity is now offered for replenishing stocks of many species which have been found difficult to raise from seeds in this country. Specimens are being imported and offered for sale in the open market direct from the cases, and, as a rule, these are received in fairly good condition, especially when the plants have been collected in a dormant state. If these are given the right treatment when received, they soon establish themselves and give a good return of flowers in their proper season, particularly the various Dendrobiums, Oncidiums, Catasetums, Vandas, etc. When imported plants are received they should be placed in a cool, airy house for some days, and gradually exposed to daylight (not direct sunshine at this season). They should be overhauled thoroughly, cutting away any decayed pseudo-bulbs or growths, and well cleansed with the aid of a sponge and small brush, and a safe insecticide, to free them of insect pests, care being taken not to injure the eyes of growing points, especially of any bulbless kinds, such as Phalaenopsis and Aerides. If small quantities are being dealt with, the plants may be fixed separately in pots or pans and kept in position by neat stakes, the roots being held securely by broken crocks placed among them to about two-thirds of the depth of the receptacles. They should be placed in shady positions, in the division best suited for their culture; heavy watering should not be practised at this stage, and the pots and surroundings should be sprayed occasionally to promote root action and renewed growth until signs of activity are showing, when some of the crocks may be removed, leaving ample for drainage, and the receptacle filled with a compost consisting chiefly of fibre and Sphagnum-moss for most of the epiphytes, adding a little fibrous loam for the terrestrial kinds. When the species are known to be lime-loving subjects, and limestone is used in the compost, as with Cypripedium niveum, etc., Sphagnum-moss should not be used, as lime or lime-water soon kills the moss, which then decays and quickly turns the compost sour. Continue to keep the surroundings moist by syringing, and as the roots and growths advance, water will be needed in increasing quantities each time the compost appears dry, and more light will be required to build up successful flowering growths. A keen search should be made frequently for any signs of imported insect pests, which sometimes appear after the plants begin to grow, as, for instance, the Cattleya fly, the eggs of which were deposited in the eye of the growth when in a dormant state, its presence being shown by the abnormal and stunted appearance of the subsequent growth which, if cut off at the base, and opened, will disclose a nest of partially developed pupae. If holes are noticed through which any mature flies have escaped, fumigating should be done to destroy them before they lay their eggs in surrounding plants; sometimes the grubs are found in the roots, where they are best killed by piercing the swollen part with a strong pin.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Thinning Fruits.—Apple and Pear trees on walls and fences have set, in many instances, an abundance of fruits, and to obtain the finest specimens there should be a judicious thinning of the crop. In some cases the trees make an effort to adjust the balance by shedding a considerable number of the young fruits, but where there are excessive crops, artificial aid is also necessary. For not only is it bad for the trees to be overcropped, but it produces a tendency to biennial bearing. All small and badly-shaped fruits should first be removed, and, if there still remains an overcrop, the fruits should be reduced to one or two per spur. In many cases whole trusses of fruitlets may be removed to the advantage of the spur, as when it is freed from feeding the fruits, the energy of the tree is concentrated on the production of fruit buds for the following year. The trees should not, at any time, suffer from the lack of moisture at the roots; there is always a risk, especially with trees on walls, of this happening. Much may be accomplished to conserve moisture by heavy mulchings of half-decayed manure and occasional soakings of clear water with the aid of a hose.

Summer Pruning.—Summer pruning, or pinching, is necessary in order to check undue vegetative growth, and to induce fruitfulness, but the operator should be guided by the variety and character of the tree. With Apples, for example, such varieties as Irish Peach, Beauty of Bath, Langley Pippin, Lady Sudeley, Worcester Pearmain and others, are essentially "tip" bearers, that is, they produce fruit buds at the tips of the season's growths. It is, therefore, necessary to exercise some judgment when summer pruning such varieties. Summer pruning consists of shortening back all side-shoots, or breast-wood, to five or six leaves from their point of origin. It tends to throw more vigour into the buds at the base of the growths, and to induce the development of fruit buds there instead of leaf-buds. It allows air and light to play their part in ripening the wood, and also favours the production of richly-flavoured fruits. Summer pruning should not, however, be done too drastically, or more harm than good may result. The two top buds on the part left may grow out, and when these have attained the length of five or six inches, the growing tips may be pinched out. It is seldom that a tertiary growth takes place. Meanwhile, the buds at the base are being stimulated and "plumped up," and will form good fruiting spurs next season. When trees tend to grow luxuriantly it is an indication that they require root-pruning, or "ringing," to restrict the upward supply of sap, and no amount of summer pruning will induce them to bear fruits. Such trees should be root-pruned next autumn, or so soon as the leaves commence to fall; the earlier the operation is carried out then, the better.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Plants in Tubs.—In gardens where facilities for protecting such plants during the winter are available, specimens of half-hardy plants are useful and ornamental for decorating the flower garden and terraces during the summer months. These may now be placed in their summer quarters with safety, provided they have been hardened off. A great deal of real pleasure may be obtained from growing good specimens in pots or tubs, and if the proper places are chosen for them in the open, they add considerably to the effect and charm of the garden. Among easily-grown shrubs suitable for this purpose are Myrtus communis and M. Luma; Punica Granatum, the Pomegranate, and its double-flowered forms; Oleanders, and Hydrangeas, which may now be had in a wide range of varieties, well-grown specimens lasting a long time in good condition. Probably there is no more popular plant for this purpose than the beautiful African Lily, Agapanthus umbellatus, which, with its umbels of rich blue flowers and handsome foliage, is one of the most desirable plants for furnishing terraces or formal parts of the flower garden.

Sub-Tropical Bedding.—Happily, sub-tropical plants are not used so freely in the flower garden at the present time as they were formerly, but where the material is available, groups of these, if used with discretion, give quite a good effect. Shelter from wind is an important factor, otherwise the tips of the foliage will soon become damaged and unsightly. A warm corner, with the necessary shelter, which will also act as a suitable background so essential if the full beauty of these plants is to be realised, should be selected, and the plants put out after being thoroughly hardened off. Many interesting and handsome subjects may be used for this form of bedding. Large specimens of Palms, Tree Ferns, Agaves and such like associate well together and give character to a quiet dell; among Palms, Phoenix canariensis, Chamaerops excelsa and C. humilis are the hardiest, but large specimens of Kentias may be used in the open in the milder parts during the summer months. Cordyline australis and C. indivisa, as well as various forms of Phormium, the New Zealand Flax, are useful; also the Blue Gum, Eucalyptus Globulus, and the Castor Oil Plant, Ricinus communis, of which the variety Gibsonii has beautiful, bronze-coloured foliage and is very effective in a sunny position

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Peaches.—As the fruits of all the early varieties in houses will now be rapidly swelling to maturity, stop pinching the shoots and finish tying down the growths, so that plenty of light and air will be admitted for the purpose of increasing the size and colour of the fruits. If pendant fruits have not been lifted up to the light, no time should be lost in the completion of this operation, although when Peaches set enough fruits and to spare, careful thinning renders this latter work unnecessary, as the best placed fruits are retained. Syringe the trees freely with soft water until the fruits show signs of ripening, so as to ensure freedom from red spider until after the fruits are gathered. Examine the borders, and if there is the slightest danger of the most active surface roots becoming dry, water well with clear tepid water, and mulch with short stable litter. Ventilation from now onwards should be on a most liberal scale and as the fruits reach full size and show signs of softening, do not allow them to hang until ready to drop into nets or hay, as is often done, with the result that more are spoiled than saved, but when dry and cool, gather the Peaches and place them in an airy Grape room to ripen.

Successional Peach Houses.—The successional Peach trees will now require syringing twice a day, and the roots confined to inside borders should receive an abundance of water besides a good mulching, especially if the trees have been checked to secure good fruits. Soils vary in quality; some loams are rich enough to produce perfect wood without the aid of much manure, and with these, generous applications of fertilizers are unnecessary, but with poorer soils, feeding of the roots, provided the drainage is good, by mulching with manure and applying liquid manure from the time the fruits are set until they are of full size and coloured, will be highly beneficial. Ventilation is equally as important as watering; it should commence in the morning with a rising temperature, after a rise of 5° over the night temperature, which ranges from 50° at first to 60° or 65° after the fruits have stoned. In the summer, Peaches will relish a night temperature of 70°, but 60°, with front ventilation, is quite high enough in the morning, this being balanced by closing the house in time to trap the sunheat, at the same time ensuring a moist atmosphere.

Late Peach Houses.—If there is any disbudding of the late Peach trees still to be done, a final thinning should be made as the young shoots are tied in; crowding of the growths, especially on late trees, should be avoided, and the shoots should be tied in at least six inches apart to allow for the full development of the foliage. After tying in, a little freedom of growth about the fruits will do no harm, as a little natural shade keeps the fruits moist and cool, conditions favourable to the production of large fruits, and preferable to artificial shading. When the fruits are ripening, fumigation and syringing should receive regular attention, and, as large borders are generally provided for these trees, labour in watering may now be economised by a good mulching with half-decayed manure, or less stimulating substances, according to the requirements of the trees.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain,
Brocket Hall, Hertfordshire.

Carnations.—Plants of Perpetual-flowering Carnations that are being grown to produce flowers during the winter months are, in most cases, ready for potting on into the pots in which they will flower. Those from cuttings rooted in November last, and which have been kept growing, will by this time have well filled their four-and-a-half inch receptacles with roots and may now be potted into six- or seven-inch pots. Personally, I favour the former if flowers are to be gathered in any quantity during the winter months. The compost for this potting should consist chiefly of good open loam, to which may be added some short, sifted manure and plenty of sharp grit; to each barrow-load of soil add a six-inch potful of bone-meal and a four-inch potful of Carnation fertiliser. The compost should be prepared several days before it is used. Firm potting is to be recommended at this stage, therefore it is essential that the compost should be in such a condition that it may be made firm without becoming caked. After potting, stand the young plants on a bed of ashes in a low, span-roofed house, if possible, until such time that the roots are active again, when they may be removed to skeleton frames. Protect them from heavy rain, and water carefully at all times, never allowing the plants to suffer through lack of moisture at the roots. Aphis and thrips are sometimes troublesome, but these may be kept in check by spraying with a Nicotine solution. Plants that are to produce flowers during the early winter months should not be stopped after the end of the present month, and certainly not immediately after potting. Stake the plants early so as to prevent the young growths being damaged.

Stephanotis floribunda.—This delightfully-scented stove or intermediate house climber will soon have passed through its first flowering stage, and will now be making a considerable number of fresh growths, which, if regulated by careful pinching, will produce two excellent crops of flowers later. This climbing plant enjoys warmth, with plenty of atmospheric moisture, and gives the best results if its roots are restricted somewhat, although the plants should receive liberal supplies of stimulants while in active growth. Good fibrous loam and peat in equal parts, with charcoal and plenty of silver sand added, should form a suitable compost for this charming climbing subject.

Nerines.—These will, by this date, have practically completed their growth; they should be stood on a shelf in full sunshine, and should receive no water until they commence producing their flower spikes in the autumn. Only by such treatment can Nerines be made to blossom successfully.

Annuals.—The conservatory or greenhouse may be kept very bright at a very small expense by the use of annuals, notably Statice, Larkspurs, Clarkias, Zinnias, Salpiglossis, Stocks, Asters, Lobelia tenuior and Petunias. These subjects are not very particular as to soil, but a rich, open compost is to be recommended. Prick out the young seedlings in well prepared soil in a cold frame, and when they have become well established, lift them and pot them in receptacles best suited to meet their requirements. Careful watering is necessary after potting, but once the plants have filled their receptacles with roots, liquid manure should be given freely.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Onions.—Beds of Onions should be kept clear of weeds, and where large specimens are wanted they should be given ample supplies of water, and a light dressing every week of an artificial manure, such as Clay's fertiliser or sulphate of ammonia, dusted along the lines and around the bulbs, but take care not to over-feed them Spring-sown Onions may now require thinning to about two inches apart, and after thinning, draw a little soil up to the plants left so as to keep them upright. At this stage, also, a good dressing of soot scattered broadcast over the plants when they are dry will be beneficial.

Potatos.—These are now growing fast and, so soon as they are nine inches high, they should be earthed up, but before doing this, give a light dressing of an approved artificial manure.

Swedes.—A batch of Swedes should now be sown to provide roots for winter and spring use. When the seedlings are large enough, thin them to ten to fifteen inches apart. The roots may be taken up and stored in the same manner as other root crops.

Kohl Rabi.—The Kohl Rabi seedlings, which were sown some time ago, will now be ready for transplanting. Make a further sowing to provide a later crop.

Autumn Broccoli.—Where the plants are ready and the ground for them has received a good dressing of decayed manure, a large batch may now be planted, so as to provide a good autumn crop, to be followed by a later variety.

Turnips.—A further sowing of Early Snowball, Golden Ball and Veitch's Red Top Turnips may be made to provide a succession of good roots. The seeds should be sown thinly, so as to dispense with thinning of the seedlings so much as possible.

Spinach.—Seeds of summer Spinach may be sown at intervals of two weeks to maintain a succession. Early-sown Spinach should be thinned where necessary and the bed hoed.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemont, Monkton, Ayrshire.

Vegetables.—Thin main-crop Carrots and Beet at an early stage, when it may be done with little disturbance to the seedlings retained. A distance of ten or twelve inches should be allowed, to permit of the free use of the hoe. Naphthalene or sheep dip should be applied immediately after thinning, either in liquid form or mixed with dry sand, and scattered broadcast, to drive off the Carrot fly. As the roots of the Carrots swell, a little soil should be drawn up around their collars to prevent greening and also as a protection against the fly. On light soil, or during drought, a mulch of short grass is of great assistance to these crops.

Early Cauliflowers.—These should be well supplied with water, followed by applications of liquid manure or a dusting of sulphate of ammonia around, but not on, the plants. Cultivate and draw soil up to dwarf Beans after thinning them, to prevent damage by wind. Runner Beans should be supplied with stakes and loosely tied to them. The main crop of Brassicas should be planted before the plants become overgrown. As a general rule twenty-four inches each way is a suitable distance at which to plant them. If pricked off in a nursery bed as previously suggested, good, sturdy plants should now be available. Lift each with a ball of soil, if possible, and transfer them quickly to their new quarters, so as to check them so little as possible. When transplanting them from the seed-bed, it will assist the plants if the roots are dipped in a thick puddle of soot and earth before planting, which operation should be done, if possible, before or during a showery spell.

The Rock Garden.—Attend constantly to the removal of weeds while they are quite small. As Aubrietias and dwarf Phloxes, and other low-growing, early-flowering subjects, pass out of flower they may be cut back; if a supply of good fresh cuttings is wanted in July or August this is essential, but otherwise large patches or plants hanging over rocks may be left untouched, or only lightly trimmed. Remove seed-pods from Gentiana verna and other choice plants if the seeds are not wanted for increasing the stocks.

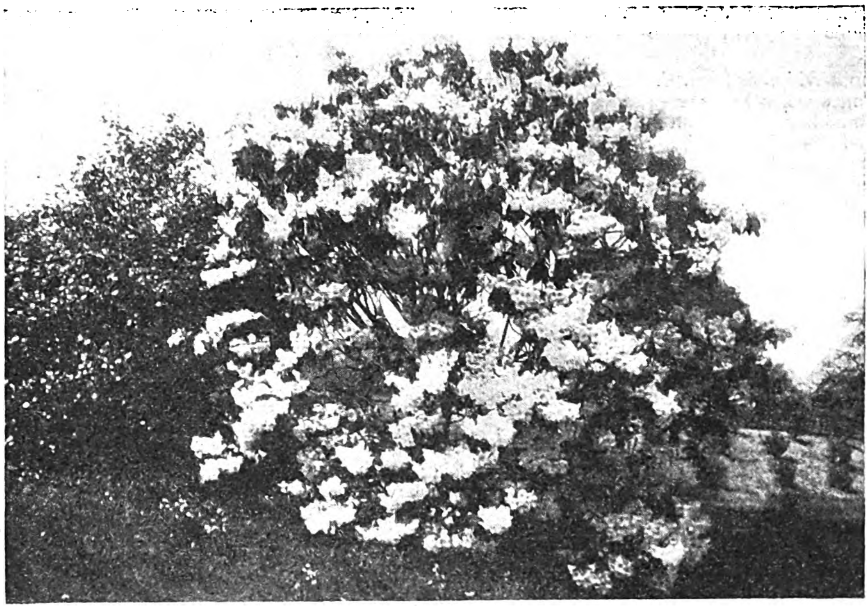

FIG. 212.—RHODODENDRON AUCKLANDII AT BRYNGARW.

(see p. 420.)

Potting.—Chrysanthemums for late work should be transferred to their flowering pots, stakes supplied at once, and the plants set in order in their growing quarters. They should stand either on a good bed of ashes, or on boards, to prevent the ingress of worms, which completely spoil and set at nought all carefully designed arrangements for the welfare of the plants. Winter-flowering Carnations should also be placed in their flowering pots at an early date, using a compost as recommended previously, but in a rougher state. See that the roots are soaked well previous to turning the plants out, or many of the best roots will adhere to the pots. Pot them moderately firmly, without the aid of a rammer or potting stick, and withhold water at the roots for a few days. Stopping of the shoots should be discontinued until the plants become established. Where a suitable house is available, these Carnations should be grown under glass. Should red spider appear, syringe with a weak solution of salt and water (one tablespoonful of salt to a gallon of water), taking care to ensure that the solution reaches the undersides of the leaves, and spray the plants with clear water on warm days.

TREES AND SHRUBS.

RHODODENDRON AUCKLANDII.

The tree represented in Fig. 212, was planted by Captain Traherne in his garden at Bryngarw, Glamorganshire, some twenty-five years ago. It is now about sixteen feet high and, except for the Camellia beside it, is entirely unsheltered. Notwithstanding the late severe winter, it has never flowered more gorgeously than this year. *C. L. Ward-Jackson.*

ESCALLONIAS.

The Escallonias comprise a genus of handsome, South American generally evergreen shrubs, with attractive, glossy foliage. Most of them make excellent covering plants for pergolas or bowers, although some of the more tender species need the protection of a wall; several of them make attractive specimen bushes, while a few of the more vigorous species are ideal hedge plants.

E. macrantha is probably the best known of the genus, and is a beautiful evergreen shrub, with bright, shining green leaves and pinkish-red flowers which are produced very freely. It is of vigorous constitution, grows very quickly, and makes an excellent hedge plant in mild localities. There is a white form of it and also a richly coloured form known as E. m. var. sanguinea.

E. montevidensis (syn. E. floribunda) is a free-flowering species bearing pure white flowers in small bunches, but it should be planted in a sheltered position, while E. Philippiana is a deciduous, small-leafed species, bearing dense panicles of snow-white flowers.

E. illinita is a gracefully branching species and one of the hardiest, with white flowers which are borne in cylindrical panicles and, in a moist atmosphere, have an almost overpowering odour; while E. Ingramii is a strong-growing, broad-leafed plant and bears clusters of bright pink flowers which are of a most pleasing shade. E. rubra is a beautiful, reddish-flowered species of compact habit, but it is somewhat tender and should only be planted in sheltered positions in other than mild localities.

E. langleyensis, raised by Messrs. J. Veitch and Sons in their Langley nursery in 1893, must be considered one of the great successes achieved by hybridisation in hardy trees and shrubs. It is the result of a cross between E. Philippiana and E. punctata, which are respectively deciduous and evergreen, but the hybrid is evergreen and an exceedingly decorative plant. It produces long, arching branches during the summer which, the following year, are clothed with blossoms borne on short twigs from the axil of every leaf. The flowers are of an attractive, rosy-carmine colour, and present a wonderful effect in June and July when the plant is at its best.

There are several other hybrid Escallonias of recent introduction which have considerable merit, among which may be mentioned E. Edinburgh, a small-leafed variety with bright rosy-carmine flowers, and although somewhat less vigorous than some others it is nevertheless a charming plant; E. Donard Seedling, a vigorous plant bearing fine trusses of pale mauve flowers in bud, opening white; and E. G. F. Ball, which has attractive, glossy foliage, a refined habit, and vivid red flowers. *A. M. W.*

FENDLERA RUPICOLA.

This erect-growing, deciduous shrub is a native of Texas and New Mexico, and belongs to the Natural Order Saxifragaceae. It is an exceedingly beautiful ally of the Carpenteria and Philadelphus, and thrives in practically any soil, if given the protection of a wall. Although quite hardy, it appears to prefer the latter, and in these gardens, grown in a southern aspect against the wall and glass of a warm greenhouse, attains the height of six feet and flowers profusely.

When in bud, this shrub is very attractive, for all the buds are rose-tinted. The flowers, appearing in April and May, are white, large, and tinted with pink externally along the centres of the petals, which are four in number. Each flower possesses eight stamens, the filaments of which are prolonged beyond the sides of the anthers into a linear lobe. The flowers are pedunculate, and are borne terminally on short branchlets, each of the latter bearing from one to three. The leaves of Fendlera rupicola are small, being about one inch in length. They are sub-sessile, oblong, entire, and are greyish-green in colour. The mid-rib of the leaf is very prominent.

Propagation may be effected by means of cuttings or seeds. *Reg. E. Moore, University Botanic Gardens, Cambridge.*

FLOWERING CHERRIES.

Of the four seasons of the year, spring gives, so far as trees and shrubs are concerned, a far greater wealth of flower and beauty than the other three seasons put together. Perhaps, coming after the bareness of winter, one notices it and appreciates it the more.

Few trees give a finer show of blossoms than the Cherries, especially the Japanese forms. In the early-flowering species the time of flowering will depend upon weather conditions. One of the earliest to blossom is Prunus incisa, which forms a small, bushy tree, every twig of which seems to be covered with flower buds which may open so early as the third week in February. The small, flesh-pink flowers are very similar to those of Prunus subhirtella, which flowers a little later. There is a form of P. incisa known as var. serrata, with distinct foliage, otherwise it is similar to the type. Both of these give very good autumn foliage effects. P. subhirtella and its form ascendens, which is the better of the two, and the variety pendula, flower in March. I do not know up to what height the type grows in its native land, probably fifty to sixty feet, but here it appears to be of bushy habit. The variety pendula is recorded by Wilson up to forty-eight feet, but I do not think we shall ever see it grow to that height in this country, where it is usually worked as a standard and on a far too short stem. If it could be worked on a stem of, say, fifteen feet or more, and an even head formed, it would not take long to form a fine specimen, as the growth is very rapid, but unless it is on a tall stem it will be trailing its branches on the ground, and much of its beauty lost.

I have tried propping up some of the branches of trees with six feet stems to try and get greater height, but they seem to resent this, and a lot of young wood began to die back.

There are three other species worth growing for early flowers, the first being P. Sargentii, which should be in every garden. It is a tree of great beauty in the early spring when opening its large, soft pink, single flowers, with its bronzy foliage, while in autumn its foliage becomes a rich crimson. It seems to be a fairly fast grower. Then there is P. pilosiuscula and its variety media. There seems to be some confusion over the two, but I think the variety media is the better plant. The type, with me, gives a small pink flower with a mass of pink stamens and, if there were fewer stamens and more petals, would no doubt be more effective. Its habit is rather a neat, upright growth with quite pretty foliage, which is rich bronze when opening. The third species I have in mind is P. Conradinae. Here again there appears to be more than one form. The best of the two has not yet flowered, but neither has the other, although it is a much older plant. It has made rapid growth, but has a nasty trick of dying back. The foliage, however, makes it an attractive plant in spite of it not having flowered yet. The flowers are flesh-pink.

Of the Japanese Cherries there are two sections, Lannesiana and serrulata; the former may be stated to include those with green foliage, the latter with bronzy foliage. But the authorities Koidzumi, Miyoshi, Wilson and, later, Ingram, differ in their classification, and one hardly knows which section any sort really belongs to. Probably, from a garden point of view, this is of small importance. The chief point is the flowering habit of the variety. At the present moment the most popular variety, and deservedly so, is Sekiyama, known to most people as Hisakura, and by the Japanese as Kanzan. The flowers are large, rose-pink and very double; the young foliage is deep bronzy-red and often turns a good colour in the autumn. The habit of this variety is rather ascending and the growths run into single leaders rather than branches. There are two varieties very similar to this, probably both are simply new names for an old plant; they are Horingi and Ohnanden. The variety Kirin is very similar, but differs in being earlier, and the flowers have shorter stems. Two varieties I have, which also appear very similar, came under the names of Eva Gauntlett and Troiaya.

Fugenzo, often known as James H. Veitch, is somewhat like the former in colour of its flowers, but its habit is rather the opposite, as it is a dense grower, the branches inter-crossing; further, the flowers have a leafy carpel in their centre which is also observed in one or two other varieties. Its flowering season is about the beginning of May.

Hokusai, or Ojochin, is usually known as Cerasus roseo pleno and is one of the commonest. It is an early variety opening at the latter part of April, with semi-double, pale pink flowers. P. serrulata, the type plant, is of widely spreading, rather rigid, habit. The flowers are comparatively small, very double and white, and the foliage rather small and of a glossy appearance.

Shirofugen, known now as albo roseo, is one of the latest to flower and is quite one of the best. It is very distinct in its flower and foliage. The buds open pink, changing to white, are double, and change to pink before falling. They have a leafy carpel in the centre and hang on long stalks. The foliage opens almost before the flowers and is often of somewhat rounded appearance.

Okumiyako (Miyako or longipes) flowers at much the same season, and is very similar to the last-named variety. The flowers are pure white, double, have the leafy carpel in the centre, and hang in long-stemmed corymbs. It does not appear to be so well-known as it ought. I think I should put the varieties Sekiyama, albo-rose and Okumiyako as the best three of the Japanese varieties commonly grown at present.

Kojima is a good thing. It flowers early, has fragrant, single or sometimes semi-double, snow-white flowers, which hang in long corymbs among its pale green leaves. It is also known as Sirotae and Mount Fuji.

Ukon or grandiflora, of the Lannesiana section, is of somewhat poor habit. Its flowers are semi-double and of a greenish-yellow shade which makes it very distinct; the foliage in its young state is bronzy-brown.

Amanogawa, or serrulata erecta, and known in gardens as Apple Blossom, is very remarkable in that its growth is perfectly fastigiate. It is a very useful plant on this account for small gardens, as it may be grown where the larger-growing Cherries would be impossible. The flowers are in clusters, pale pink, often semi-double, and fragrant. The translation of the Japanese name is Celestial River, and equals our Milky Way. I suppose the English name Apple Blossom applies to the flowers, but this could also apply to other varieties very similar in colour and form.

Two other Cherries I would certainly include. The first is the double form of our Wild Cherry, P. Avium var. flore pleno. It flowers so very freely and regularly that it deserves its place. The other variety is the double-flowered Morello—P. C. Rhexii flore pleno. It is a slower grower and makes a finely shaped bush, flowering later than P. Avium var. flore pleno, and has very double, white flowers. None of the Cherries should, in my humble opinion, ever be pruned, except in case of necessity; the Japanese variety Sekiyama is liable to send up long, leading shoots. I have tried pruning with a view to getting them to branch, but they just go ahead again and are best left alone. Taking them all round, I doubt if any family of trees give such a wealth of bloom as these flowering Cherries, and so consistently. There are a large number of other varieties, but being as yet very scarce, I have omitted them. *Prunyrus, Hants.*

INDOOR PLANTS.

COMBRETUM PURPUREUM.

Combretum purpureum is a tropical climber of great beauty, and being of less vigorous growth than many of the climbers usually found in our stoves, it makes an excellent subject for clothing a pillar or rafter.

The flowers are a lovely scarlet-crimson, and, although small individually, are borne in a dense spike often six inches long, which later develops into a somewhat fan-shaped panicle. The spike is not cylindrical, as the blossoms stand erect on the upper surface. The rich, dark green leaves are ovate-lanceolate in shape and form a delightful background for the flower.

C. purpureum had a reputation at one time as being difficult to grow from cuttings, but the late Mr. Irwin Lynch dispelled this idea.

The compost that suits this plant best is one of equal parts good fibrous loam and peat, with a generous amount of silver sand and charcoal lumps added to ensure porosity and sweetness. Pruning should be done each autumn by cutting back the longest growths to one or two buds. The specimen here at Cambridge is at present just coming into flower; it is planted out, and climbs up one of the supports of the Palm House. *F. H. Wright, University Botanic Gardens, Cambridge.*

CLERODENDRON THOMSONAE.

There are many beautiful stove and green-house plants worthy of note, but none is more attractive when in flower than Clerodendron Thomsonae (syn. C. Balfourii).

This subject is by no means easy to cultivate, or, at any rate, to bring to perfection, perhaps the most important point in successful cultivation being the maintenance of a steady, even temperature all the time the plants are growing, any fluctuation having a tendency to hinder growth. A temperature of 70° by day and 65° at night should be maintained throughout the growing season. Another important factor is watering. Although this plant delights in moisture, over-watering is bound to ruin it, and, moreover, particular care in watering is necessary when the plant is in flower, as too generous a supply of water at the roots at this stage will cause the flowers to drop. When admitting air to the house, the creation of draughts should be avoided. Very little air is necessary and, unless the night is very warm, only a little top ventilation is required.

Propagation may be effected either by seeds or cuttings. The seeds germinate freely if sown in a compost of good fibrous loam and fine peat in equal parts, with plenty of charcoal and silver sand added. After sowing the seeds cover the pots or pans with glass. Four or five cuttings may be inserted in a three-inch pot and placed in a propagating case over gentle bottom heat. Established plants usually start growth towards the end of August, when each plant should be examined so as to ascertain whether any surface dressing is required. A compost similar to that for sowing the seeds should be used, and, so soon as the plants commence growth, ample moisture should be afforded them, both at the roots and by means of overhead syringing—the latter should be done twice a day at least, three times if time and weather will allow. The plants should be given every encouragement to make growth until the beginning of March, when those required as specimen plants should be tied to the trellis and trained.

Many growers prefer to train them balloon-shape, which is done by securing the frame to the rim of the pot in which the plant is growing and training the growths over it. During the month of May the plant commences to flower and continues for a month or six weeks, and a beautiful sight it is, with its bright red petals, and the white, waxy calyx affording a most striking contrast. When the flowers are about to open, the temperature of the house should be either lowered or the plants moved to a cool house; this will not harm them in any way; in fact, this latter method is the best, for plants kept in a stove too long will lose their flowers prematurely. As the flowers begin to fade they should be cut off with a length of stem and two or three pairs of leaves; in this manner the plants receive all the pruning necessary.

To obtain a succession of bloom, plants should be started into growth at different periods; by this means Clerodendron Thomsonae may be had in flower for about six months. *G. B.*

SAINTPAULIA IONANTHA.

This beautiful, little warm-house plant, often referred to by gardeners as The Stove-flowering Violet, grows only about three or four inches high, and produces a number of pretty, deep blue flowers during the winter months. It is easily raised from seeds or propagated by leaf-cuttings. Leaf-cuttings root readily if inserted in a sandy compost, and placed in a propagating case, in a warm house.

Seeds should be sown from January to March, in well-drained pots or pans containing a compost of loam, leaf-soil and sand. These should be placed in a temperature of from 60° to 65°, and the seedlings treated in practically the same way as that recommended for Gloxinias. Five-inch pots or pans will be quite large enough in which to flower the plants.

Saintpaulia ionantha makes a beautiful edging for the stages of the stove or intermediate house, or for groups of plants, while used in small vases it is admirable for table decorations. *E. Baker, Garston Manor Gardens, near Watford, Herts.*

OURISIA MACROCARPA.

At Chelsea Show a plant under the above name (Fig. 213) was shown by Lady Aberconway and Hon. H. D. McLaren. I can find no reference that this plant has ever been introduced, although there is no reason why it should not be so. It is closely allied to O. macrophylla, both having white flowers, and a similar habit of growth, although O. macrocarpa has the larger flowers. The chief differences are that the last-named has stout, glabrous or nearly glabrous stems and leathery leaves, while the other has more slender, pubescent stems and sub-membranous leaves. Light was beginning to fail in the tents by the time I observed the plant, to be able to note these characteristics, but the large, white flowers were very conspicuous and numerous, on a stout, upright stem. O. macrocarpa is recorded from many districts in the South Island, New Zealand, from sea-level to an altitude of 3,500 feet, and flowers from November to January in that island. It is the finest plant of the eight described species of the genus in New Zealand. At the same show, O. alpina was accorded an Award of Merit. Previously recorded awards include a Silver Knightian Medal for O. coccinea, which has little but its colour to recommend it. *J. Fraser.*

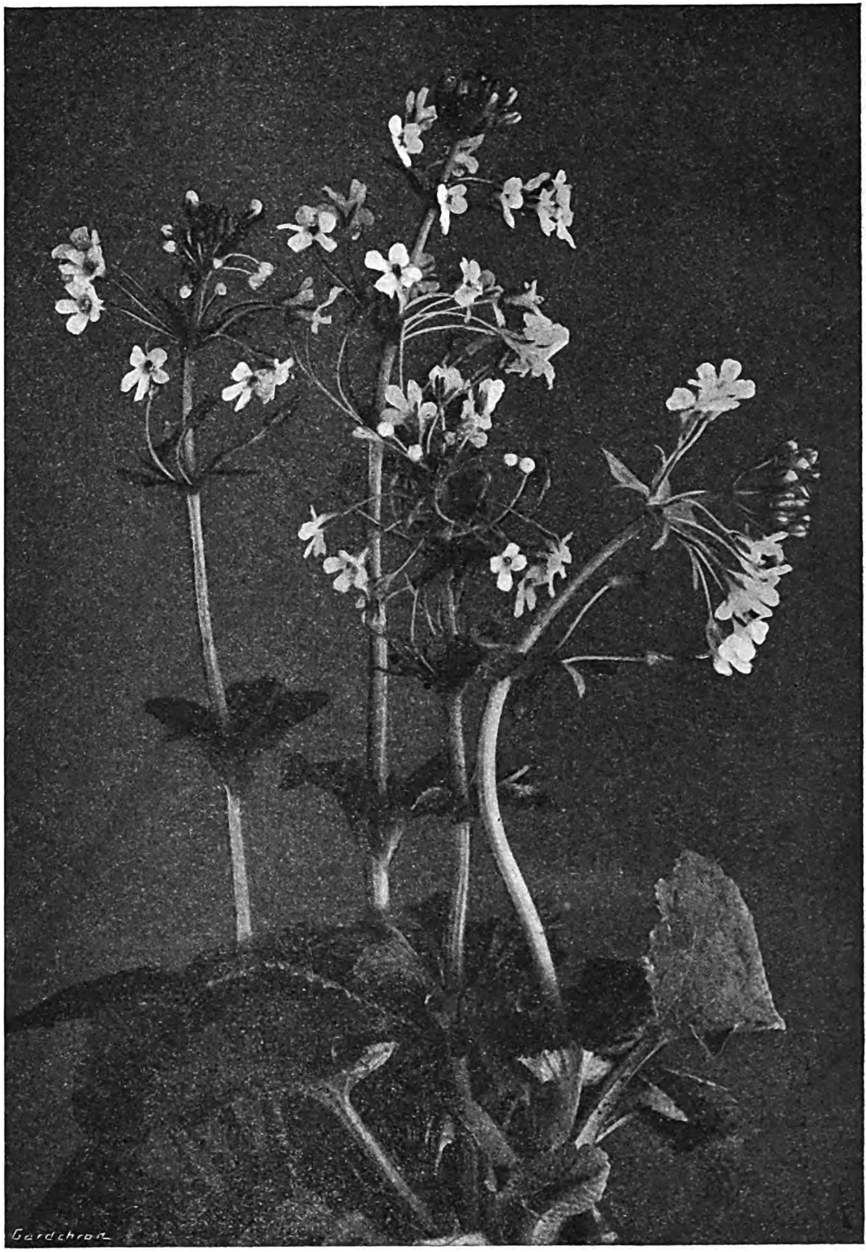

FIG. 213.—OURISIA MACROCARPA.

ALPINE GARDEN.

SAXIFRAGA WALLACEI.

A FRIEND recently sent me a plant of Saxifraga James Bremner, which is stated to be the largest flowered of all the white mossy Saxifrages. In a covering letter he gave me the information that S. James Bremner was finer than S. Wallacei which was not a good doer. The latter remark surprised me, as, until then, I had not heard of any one having trouble with this glorious plant. But when one hears of such an experience it sets one trying to discover how far this has any connection with any foibles the plant may have. Within a day or two, an opportunity of comparing experiences occurred when an experienced cultivator of hardy and other flowers visited me, and he told me that at Dumbarton he experienced difficulty with S. Wallacei, which he found only succeeded in a rather dull corner and in poor soil.

I have cultivated this Saxifrage under different conditions for close on forty years, and have always found it grow and flower freely. In comparison with S. James Bremner I observe that the latter has rounded flowers, possibly a trifle larger than those of S. Wallacei; but those of S. Wallacei are of a purer whiteness. I have not had S. James Bremner long enough, however, to make a fair comparison, but I find that S. Wallacei grows and flowers very freely in light, dry soil and is especially fine in a double wall.

The parentage of S. Wallacei remains a little obscure. In 1903 I had a certain amount of correspondence on this subject and appealed to my departed friend, Mr. Robert Lindsay, of Kaimes Lodge, Edinburgh, formerly Curator of the Royal Botanic Garden, Edinburgh, for information on the origin of S. Wallacei. The following extracts from his letter, dated July 1, 1903, may be of interest to Saxifrage lovers:—"S. Wallacei was raised by George Wallace, of the Dean Cemetery, Edinburgh, from seed of, I think, S. Maweana or S. corsicana, and I think the plant must be a hybrid; at all events I have over and over again failed to raise a single plant of S. Wallacei, the seeds being bad." Mr. Lindsay proceeded:—"S. Forbesii is American, my Willkommianum is undoubtedly Spanish. The 'Index' gives S. Camposii as a synonym both of this and S. Wallacei, which is simply absurd." The late Reginald Farrer, in his *English Rock Garden*, discusses this question, but does not clear up the point of parentage in a satisfactory way, but, as he states, "dates make it unlikely that S. Maweana had any share in it, and one of the most probable parents is S. trifurcata . . . . . ." S. × Wallacei is said to have been growing at Kew in 1867; whereas S. Maweana was not introduced until 1869."

Personally, if we must dismiss S. Maweana, I am of the opinion that Farrer's suggestion of S. trifurcata does not seem far wide of the mark. By the way, that gifted writer disposes of the name of S. Camposii as a synonym of S. Wallacei, Merror, which originated through the *Botanical Magazine* having figured it as S. Camposii, which species was not at that time in cultivation. *Dumfries.*

ANTHEMIS CUPANIANA.

AFTER last winter, the revision of one's beliefs respecting the hardiness of old and new plants has to be in two directions—one of a cheering kind, resulting from the survival of plants of doubted hardiness, and the other, much less cheerful, in fact, rather depressing. The first includes the treasures which have survived, and the second those which we have trusted for hardiness and have found to be too tender for such seasons as the past winter.

I have grown Anthemis Cupaniana (montana) for at least twenty-four years and have hitherto found it withstand all the winters we have experienced until this last one. Now, I am viewing with grief and disappointment what was once a noble plant of this Chamomile, but which is now a mass of withered branches and leaves, which covered with beauty the boulder over which it hung. No longer is that boulder veiled with silvery foliage and beautified with the added charm of the pure white flowers, and the plant is evidently to be written down among the departed glories of the garden. This is contrary to one's former experience and in direct contradiction to the teaching of works on hardy flowers and of catalogues. According to Farrer, it is "perfectly hardy." He adds, "it came under a suspicion of tenderness which has by now been utterly dispelled." Of course, its Italian origin has not been too reassuring on this point, but this is not always a sign of tenderness, as we have very many Italian plants which are quite happy in this land of ours. A. Cupaniana, in my opinion, should have a light soil and a sunny position.

PENTSTEMON DAVIDSONII.

CONSIDERABLE controversy has centred about the name of this little shrubby Pentstemon, and the confusion resulting therefrom in nurseries and private gardens is very great. Personally, I am inclined at present to continue to use that of P. Davidsonii, with which Farrer appeared to be content, although his acceptance seemed to be partly because he did not admire the colour of the flowers and that he considered the name in this case was negligable. P. rupicola, P. Menziesii and P. Douglasii appear to be the other titles most commonly used for it, but I think P. Davidsonii holds the field in point of general acceptance. Farrer's colour description is certainly far from enticing. He states it has: "fleshy, little, oval-toothed leaves of bright green, clothing the stems of a fat and minute branching shrublet of an inch or two in height that end in baggy bugles of a ferocious red-mauve, most terrible and breath-taking to look upon in the sun." I do not think all who grow P. Davidsonii will agree with this *in toto*, as a good deal depends on the surroundings. With plenty of greenery about, the hardness of colour is modified, and the leaves of the Pentstemon in themselves are so fresh and green that they assist in this direction. While P. Scouleri, although not killed, suffered severely in a similar position, P. Davidsonii was perfectly unscathed during the past winter growing on the top of a low double wall, flanking a flight of steps and well exposed, with a south-west exposure. It will also thrive in a moraine without lime. *S. Arnott.*

VITTADINIA TRILOBA.

OF such easy cultivation that in many gardens it has naturalised itself, Vittadinia triloba, better known as Erigeron mucronatus, is an invaluable subject for the summer adornment of the rock garden. It is also extremely useful for furnishing the crevices of rock walls, or of stone-flagged paths, and may even be employed effectively in sunny borders or as edgings to paths, for, provided it has a sunny position and soil not so rich as to encourage luxuriant growth, this dainty little subject will flourish and produce its Daisy-flowers, opening pink and changing to white with age, in unbroken succession throughout the summer months, the first having already opened with me.

V. triloba is perennial, and may be increased by division or from seeds, which are usually produced quite plentifully; when once established, this dainty subject will seed itself about, so that in a very short time colonies will have sprung up about the single parent plant, to be transformed in the summer into a cloudy mass of pink and white. And, although V. triloba scatters itself about so freely, it seldom infringes upon the livelihood of its neighbours, for there is no suggestion of coarseness about its appearance or mode of growth, and it will ever retain its unassuming nature, growing in close vicinity to other plants, yet, withal, in a companionable manner.

It is neat and compact when not in flower, and when in blossom forms a loose, open mass of branching stems some nine inches high, the numerous, small, Daisy-like blooms presenting every intermediate shade between white and deep pink. Comparatively poor soil would appear to suit it best, and it cannot have too much sunshine. *M. W.*

HARDY FLOWER BORDER.

ZAUSCHNERIA CALIFORNICA VAR. MEXICANA.

THERE have been many disputes regarding Zauschneria californica and the species or variety mexicana, and forms such as splendens, and it would be both useless and unwise to make any definite statements here without full possession of the facts. Suffice it to state, the Zauschnerias are natives of sunny California and Mexico, are popularly termed Californian Fuchsias or Humming Birds' Trumpets, and are indispensable rock garden or border plants, although not generally considered to be hardy.

In gardens, Zauschneria californica is herbaceous, bearing each year a multitude of twelve-inch, fragile stems, set with small, narrow, slightly woolly, grey-green leaves. In summer and autumn a fair proportion of brilliant, reddish-orange or vermilion, tubular flowers is usually borne, hanging pendant from the stems.

Zauschnerias are generally given some protection in winter, yet three specimens have lived out-of-doors for three years in a north-midland garden without such precautions having been taken. Even the severe weather of the past winter has had no ill-effect, beyond the usual cutting of the plants to the ground; new growth has since been made. These are of Zauschneria californica var. mexicana, as sent out by a well-known firm. One is planted at the side of a path, and at the base by a large rock facing south, while the other two are in deep, vertical rock-clefts with a south-east aspect. The compost for all three is the natural rather worn-out garden soil, plus abundant coarse limestone chippings. Curiously enough, none of the plants has yet flowered, although each year they have come up again stronger than ever. However, as they are now well-established, it is to be hoped that abundant blossom will be produced this year, given a sunny summer and autumn. The catalogue description is that of "a twelve-inch mass of flaming scarlet." Another consignment of Z. c. var. mexicana, received from an Irish nursery of note, was planted at an unfavourable time; they were frozen hard in the ground and perished soon after arrival.

In exposed gardens it is usual, and indeed advisable, to propagate Zauschnerias every year, so as to keep a stock under glass through the winter in case of loss among the plants outside. Increase may be effected by division in spring, or by cuttings of side-shoots in late summer, and pure silver sand or a very sandy compost will be found a suitable rooting medium. *L. B. C.*

VIOLAS.

THESE extremely useful plants are increasingly popular among gardeners and other flower lovers, and deservedly so. Not only are they hardy, but the flowers last a long time, and the plants are adaptable to almost any position.

Ground intended for the reception of the plants should be well dug and have some old manure, a little bone-meal, and a dusting of old soot added. In order to assist root growth and thus build up plants to withstand drought, it is well, after placing the Violas in their permanent quarters, to keep all flower buds picked off for a week or two.

The uses to which Violas may be put are many. In the garden they make capital edgings to Rose beds or the herbaceous border; and they will thrive well in shady places. They are also useful for covering bare spots, and for "carpets" to taller growing plants. A small circular lawn-bed containing a weeping standard of Rose Lady Gay surrounded by White Swan or Newton Mauve Violas looks well, and lasts well for a long time. As beds of distinct varieties, on lawns, a pleasing effect may be obtained, and, perhaps, in this way the Viola is seen at its best. For indoor use, such as for table decoration, flowers placed in low receptacles are especially pleasing.

Violas delight in moisture and during hot weather a good watering twice a week is desirable. On light soils it will be found advantageous to afford a mulch of manure. In growing Violas for exhibition one needs, of course, to go to a little more trouble. One of the best media in which to plant is Surrey loam. Each plant needs a foot of space, the stems being restricted to an average of two to each plant, and the buds to one on each stem. Given occasional waterings with liquid manure, and clear waterings between, the plants will do well and give large blooms.

A selection of varieties for exhibition includes Rena Loan, Edith Melville, Criss Littlejohn, Drummer Wilson, Kathleen Condry, Mrs. A. Stevenson, Moseley Perfection, Moseley Ideal, Nurse Cavell, Pink Stripe, Robert Black, C. Blair, Andrew Jamieson and Clifford Holden.

For garden decoration, in addition to many of those named above, the following are suitable :—Bullion, Blue Cloud, Fred Williams, Maggie Mott, Newton Mauve, Moseley Perfection, White Swan, Bridal Morn, Mauve Queen, Queen of Whites, Purple King, Admiration, Golden Sovereign and Rosy Morn. *James A. Paice, Copseham, Esher.*

THE BREAKING OF TULIP SPECIES.

It has generally been supposed that the change known as "breaking" is confined to the garden Tulips and does not extend to the species. In my recent book on the Tulip, I wrote: "Breaking has not been recorded among the true species," but in the week of publication evidence was obtained to deny that statement.

In the first place, Miss D. M. Cayley, who in 1928 succeeded in transmitting the presumed infection that causes breaking, by grafting together broken and unbroken bulbs, repeated the method and grafted broken bulbs upon normal bulbs of T. Eichleri and T. Greigii. Most of the bulbs of T. Eichleri thus made to grow in living contact with a broken variety broke this season, as did two bulbs of T. Greigii. The breaking was less marked than with the garden varieties in that the perianth segments showed no streaks of the yellow ground. Instead, they were marked with flecks and streaks of a darker scarlet, a form of variegation which I have seen in some broken forms of the English Tulip. The foliage, however, possessed the characteristic mottling of dark and lighter green; the size both of the flower and of the whole plant was reduced as far as could be judged from the small numbers experimented upon, and there appeared to be some tendency to develop torn and laciniated edges to the petals.

Further, a careful examination of the stocks of Tulip species grown at the John Innes Horticultural Institution showed that specimens of several species had broken spontaneously in a somewhat similar fashion, where no breaking had been observed last year. Undoubtedly, 1929 is a "breaking year" at Merton. Garden varieties grown here last year have broken wholesale; in many cases they were least desired so to change. Perhaps this may be connected with the heat and the prevalence of aphis last season, but the agent transmitting the presumed virus of breaking has not yet been definitely ascertained. Among the species in which breaking has been observed this season are three, T. suaveolens, T. praecox and T. armena, which are of doubtful status as species. Each of them has been regarded by some authorities as an early stray from gardens, and possibly only a variety within the garden Tulip complex.

But of good species, the following have broken: T. Kaufmanniana, T. Clusiana, T. Tubergeniana, T. Orphanidea and T. Batalinii. In all these cases the foliage showed the characteristic mottling; usually the colour change in the perianth segments was a flecking with a darker colour, but in T. Clusiana there were white streaks in the crimson on the backs of the outer segments, similar to the usual form of breaking in garden Tulips.

It may thus be concluded that breaking is common to all the Tulip genus and is not confined to the garden forms. It is a pity, because the species are not improved thereby, but are rendered distinctly poorer and less brilliant. Those who maintain a collection of species would be well advised to eliminate the broken forms whenever they appear, so as to minimise the chance of the infection being carried over.

As a further demonstration that the capacity for breaking runs throughout the Tulips, I have this year verified the fact that self yellow Tulips will break. Among my seedlings are several that open a light primrose-yellow and gradually bleach until they are practically white when mature. Some of these have become very distinctly broken as regards the foliage, and close examination of the perianth segments shows that the yellow colour is now disposed in stripes and streaks with a white ground between. One or two of them show also an occasional thin line or streak of red. In these seedlings the colour is the second flavone yellow of the Tulip, which is confined to the cuticle and to which is due the "shot" effect of certain varieties like John Ruskin or Cardinal Manning. On breaking, this faint yellow segregates into streaks, just like the anthocyanin red or purple segregation when the ordinary coloured varieties break. But I have observed the same breaking in Inglescombe Yellow which has a true yellow ground, *i.e.*, a plastid colour located in the mesophyll. A broken Inglescombe Yellow shows, on close examination, two slightly different shades of yellow disposed in stripes and streaks, and here and there a thin, defined line of red, as though a very small amount of crimson anthocyanin colour, which had been invisible in the normal breeders because it was uniformly diffused over the whole segment, had been gathered together into one or two small areas. Careful search will reveal similar appearances in other yellow self Tulips. *A. D. Hall.*

ARTHROPODIUM CIRRHATUM.

The genus Arthropodium consists of ten species scattered over Australasia. Both New Zealand species are endemic, and A. cirrhatum is the more noteworthy of the two. The Maoris know this plant as the Renga-renga, but among Europeans it is more often referred to as the Rock Lily, and sometimes as the Renga Lily.

Arthropodium cirrhatum, Br., which is synonimous with the Anthericum cirratum of Forster, is figured in the *Bot. Mag.*, t. 2,350. This attractive plant is a tufted perennial herb, producing numerous fleshy roots which facilitate division, always an easy method of increasing a stock of plants. Growing to a height of from one to three feet, A. cirrhatum (Fig. 214) produces a large number of rather fleshy, light green leaves, which vary from eighteen to thirty inches in length and are usually about two inches broad. They are flaccid, sub-distichous at the base, lanceolate in outline, and tapering gradually to a long, narrow tip. The numerous small, white flowers are borne in much-branched panicles, some of the branches of which attain quite nine inches in length. Each primary branch is borne in the axil of a broad, foliaceous bract.

The dianty white flowers are very showy in the mass, each being about an inch in diameter, with a typical Lilaceous calyx and corolla, and provided with stamens of exceptional beauty. The filaments are thread-like at the base, and just above the middle they bear a thickened, woolly appendage which is produced downwards into two fluffy tails, resembling tiny, rosy-pink or orange "bottle-brushes."

Its native habitat is the North Island, and the northern half of the South Island of New Zealand, where it is often fairly abundant on rocky cliffs near the sea, and for this reason it should become a welcome and useful member of seaside gardens in the south and west of Britain.

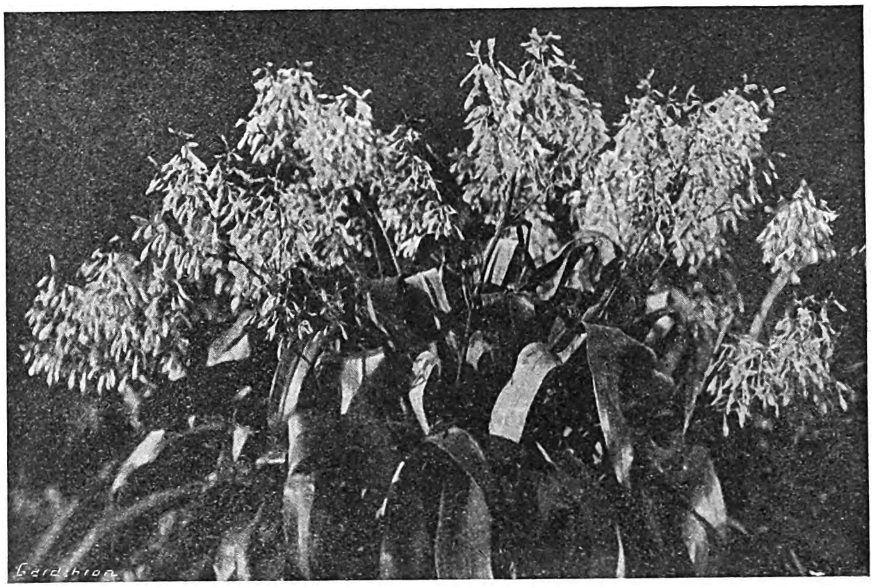

FIG. 214.—ARTHROPODIUM CIRRHATUM.

Of the easiest culture and growing in almost any soil, provided a fair supply of water is available during the flowering season, it flourishes when exposed to full sunshine, and I have it growing rampantly under Araucaria imbricata, a situation in which few notoriously shade-loving plants can be persuaded to feel at home.

A. cirrhatum has been cultivated for many years, and although introduced into Britain about 1821, it never seems to have enjoyed a wide popularity, because it is seldom seen in gardens, nowadays, which is rather surprising when one considers the merits of this plant and the accommodating nature of its demands.

This most adaptable subject will thrive in any fairly mild climate, where it can be grown in the open herbaceous border, or planted in pockets in a moderately large rock garden. It could be used successfully to furnish lawn vases, etc., instead of the overworked Pelargoniums, which are so much in evidence for that class of work. The bright, evergreen foliage is not unattractive, and during the flowering season the pleasing white flowers, which are borne in great showy masses, are very attractive. Where it would not prove hardy it could be used in the conservatory, either grown in the beds, or potted and grown in cold frames. If potted up it should be allowed to grow naturally with no attempt at forcing by stimulants or the aid of artificial heat. This interesting plant may be readily increased by means of seeds or offsets, both of which are produced freely. *A. W. Anderson, Dunedin Botanic Gardens.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

THE PLANT-LIFE OF THE BALKAN PENINSULA.

THIS volume* is important, not only for its intrinsic value as a study of the plant geography of the Balkan Peninsula, but also as the first-fruits of a series of monographs dealing with vegetation and plant distribution. There has hitherto been nothing in English comparable with the series *Die Vegetation der Erde*, edited by Professors Engler and Drude. It was in that series that Dr. Cockayne had to publish his work on the *New Zealand Flora*. This reproach is now to be wiped away, and we welcome the series as well as Mr. Turrill's book.

The book is an outcome of the war of 1914-1918. Twelve years ago the author was with the Salonica army. His interest in the rich and significant flora of Macedonia was roused, and subsequent visits to areas which in 1917 would have been sadly "unhealthy," much herbarium and library research, and the study at Kew of living Balkan plants, have been the equipment for his work. He has collected and digested for it a vast quantity of material—material difficult to get and intractable to arrange—with great patience and thoroughness, and has been able to arrive at general conclusions with regard to the history of the flora and vegetation of the Balkan peninsula.

The plant life of the peninsula is, of course, much less well-known than that of the more accessible regions of Europe. Remoteness is not the only deterrent; does not Mr. Turrill devote space to the indirect influence of brigands upon it? It is, however, so rich, particularly in its large number of unique forms, that it rewards particular attention. In the north, the central European flora comes down into the region; from the south comes up that of the Mediterranean; and on the east, the islands of the Aegean are stepping-stones from Asia Minor, and are, in fact, the remains of a geologically recent land-mass. Across this, as on a highway, species travelled both eastwards and westwards, but mainly westward and along two routes, the northern through Thrace to Bulgaria and Macedonia, and the southern through Crete to Greece.

The earlier part of the book is a general description of the peninsula, its physical features, divisions, geology, soils and climates. For the purposes of his study, the author divides the region into sixteen districts, and on this basis works his analyses and classifications. The flora is first examined in a broad way with regard to its forms, flowering periods, habitats and zones of altitude, and then with regard to the plant communities and their stages of succession. A long chapter on the influence of man, especially in forest destruction, follows. In another place, Mr. Turrill writes of the "enormous changes" caused by this exploitation, and pleads for the thorough botanical exploration of such areas as the Rodope massif and Strandja Planina as "decidedly more urgent than that of western China or tropical Africa." Might not such a scheme be organised next year as a main work of the International Botanical Congress at Cambridge? Commercial development is not neglecting the Balkan Peninsula, and there is the danger that these primitive areas may be lost for ever.

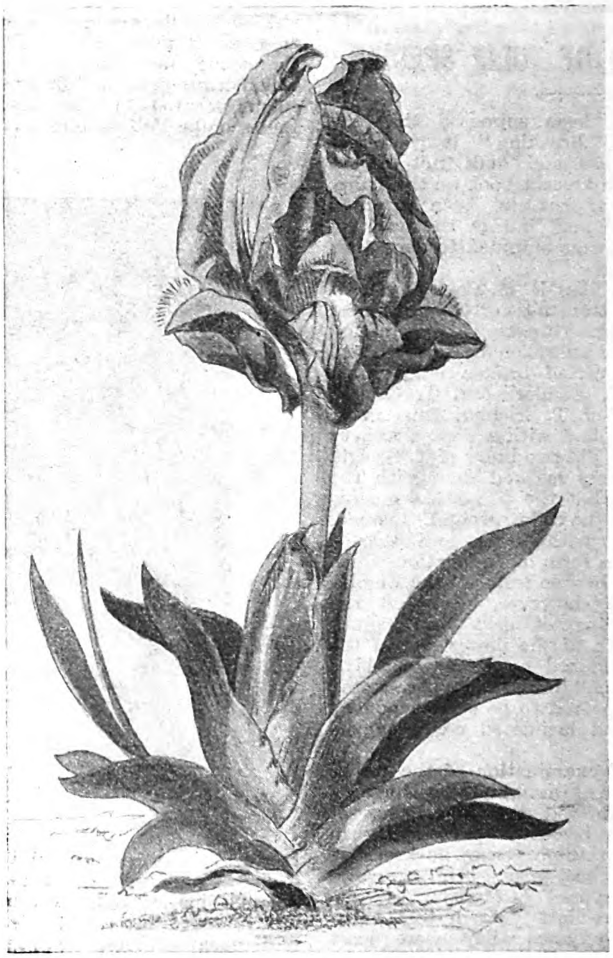

FIG. 215.—IRIS MELLITA (PUMILA) FROM AHLEM DAGH.

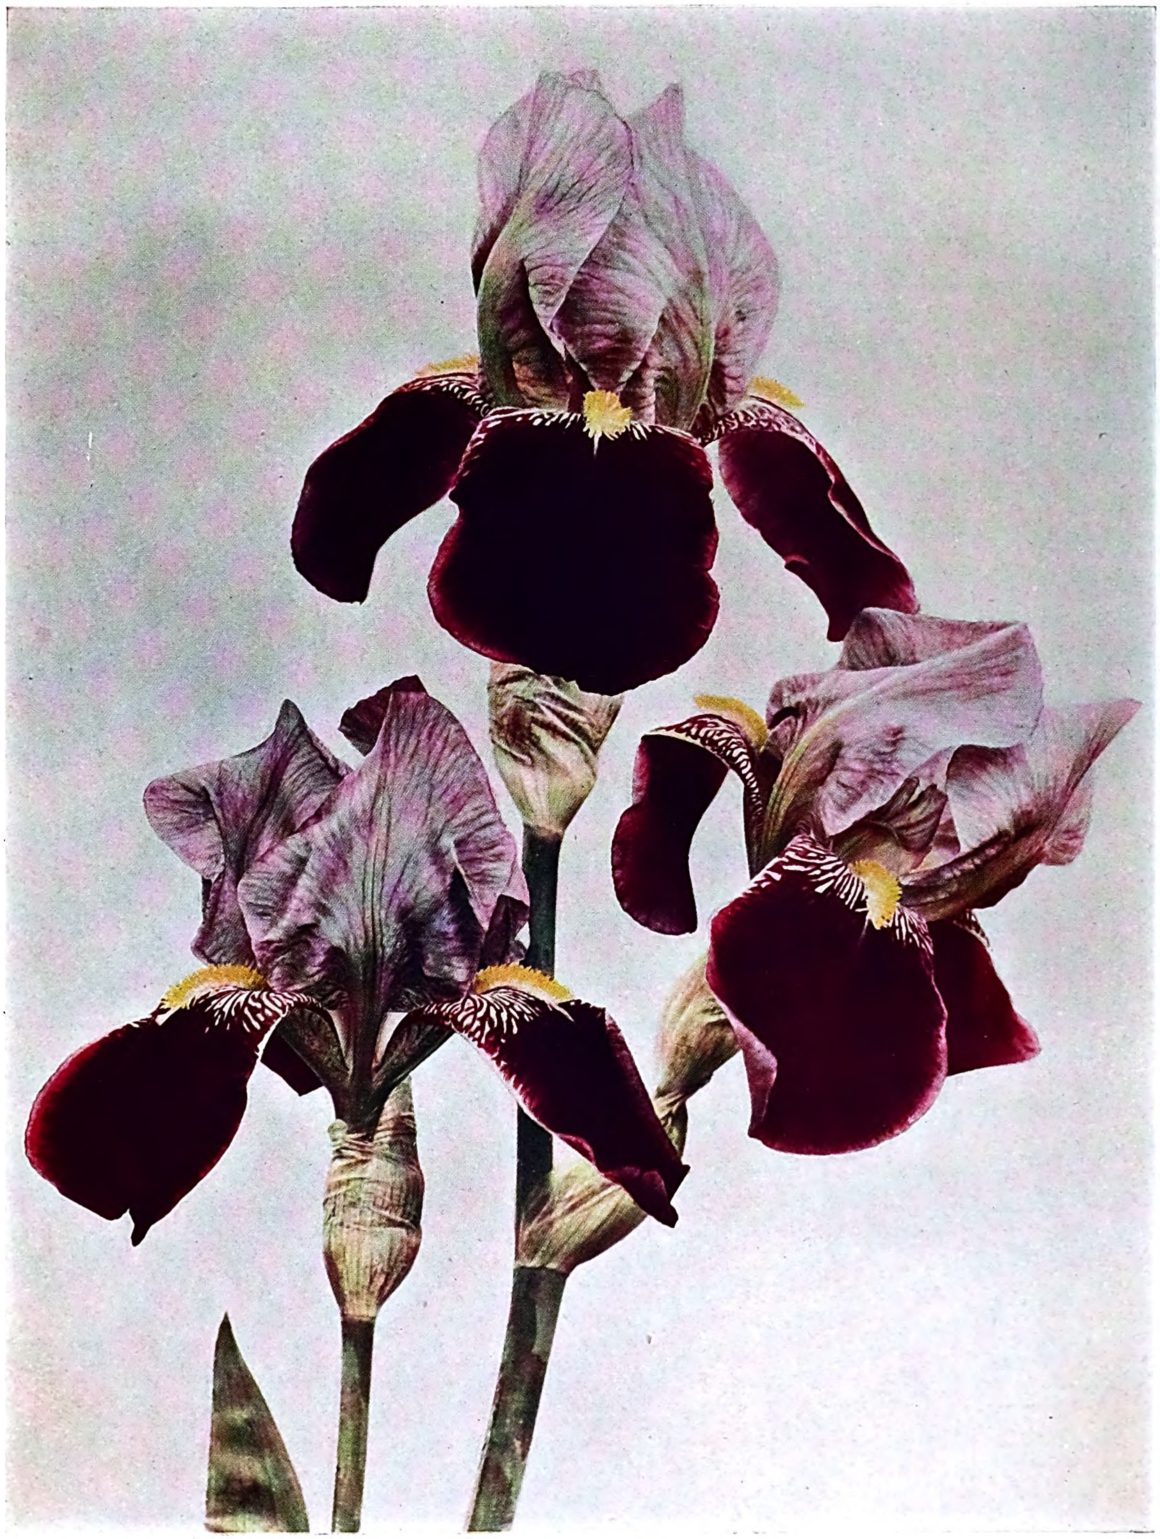
We then come to a summary of the distribution of a series of the seed-bearing plants of the peninsula. There are 126 families of such plants, with 6,530 species. Each family is dealt with in order, and notes are given of the occurrence of species in the districts. Then each of the districts is dealt with and the information just given is summarised for it. This leads to a tentative scheme of division of the Balkan peninsula into natural botanical regions. This is "proposed as a result of ten years' studies," but with the reservation that it will need modification and sub-division with further investigation. This scheme gives sixteen regions in six main groups, and provides a valuable framework for study; a map illustrates it. It is succeeded by a chapter, the longest in the volume, in which the author examines the connections of the Balkan flora with that outside the peninsula—or, rather, he examines the distribution within and outside the peninsula, and from the results of his lists seeks to establish the connections.

This is followed by what, to a reader mainly interested in horticulture, is the most alluring chapter in the book. It deals with endemic (including relict) species, *i.e.*, species whose known distribution is entirely within the peninsula and the islands. A table of the genera sets out their occurrence according to the plan of districts on which the book is arranged, and a second table gives the occurrence of those which are found in one only of the districts. Maps help to the realisation of the distribution, and notes are added on each family. The importance of all this can be gauged from the fact that of the flora of 6,530 species, 1,754 are endemic. Detailed as Mr. Turrill's work in this department seems, what is given is only a summary. The amount of investigation that lies behind it may be estimated from a full account of the twenty-five endemic Compositae of Crete, which he gives to exemplify his methods. The majority of the Balkan endemics have, he considers, originated as species within the Balkan area. A few, about sixteen, of the endemics are, however, of special interest as survivors from an older flora than that prevailing now—they are either actually old as species, or they represent old types. These, and with them other relict species which occur outside the area as well as within it, are discussed at length. In this group, with the distinction of a map all to themselves, appear the Balkan Gesneriaceae, the pride of the shaded clefts of the rock garden, the Ramondias and Haberleas. Mr. Turrill notes, as the most interesting parts for the study of relicts, northern Albania and districts around, the Rodope massif, and the Caucasian-Pontic communities of eastern Bulgaria. He ends this section of his book with an examination of Dr. Willis's "Age and Area" theory as applied to the peninsula, and the book

---

* *The Plant-Life of the Balkan Peninsula.* A Phytogeographical Study. By W. B. Turrill, M.Sc., F.L.S., Assistant in the Herbarium and Lecturer in Botany at the Royal Botanic Gardens, Kew. Oxford: The Clarendon Press; price 30s. net.



IRIS BRUNO.

itself with a modestly cautious summary of the floral history as deduced from the data. Mr. Turrill indicates lines of future investigation, and, doubtless, his collection of facts will be amplified and his general conclusions may be modified here and there, but in grasp of detail and width of view his work maps the field.

One small matter. The author refers to the inferior Apples, and our own opinion on the spot was that good Apples could be grown if only suitable varieties were introduced. But he does not mention the Quince as cultivated, except in Crete. Our recollection of excellent Quinces in the Monastir neighbourhood is vivid, and as a matter of fact, trees of the Serbian Bereczeki ard Vranja Quince can now be obtained in England. *W. R. J.*

COLLECTING IRISES.

In my early days, although I appear to have wandered into countries and mountains off the beaten track of travellers, my interests lay in other directions, and if I collected at all, it was only odd plants which at the time attracted my attention. I am, therefore, conscious that the observations which I have to offer, in response to a request, must be limited to a comparatively small area.

IRIS PUMILA AND ITS VARIETIES.

Anyone given to wandering in south-east Europe is sure to be attracted by this very small and fascinating Iris, with its several variations. It has a wide distribution, extending from the Adriatic to the Black Sea coast in the north, and throughout Greece to the Aegean Sea in the south. It crosses the Bosphorus, and is found on the hills in the neighbourhood of Constantinople, as well as on the Dardanelles peninsula. Although the name is common, the true dwarf I. pumila is seldom met with in gardens, and is difficult to cultivate. The varieties usually found in catalogues are hybrids with I. pumila parentage, and are plants of easy cultivation and very floriferous. Fig. 216 represents the true dwarf Iris pumila, from plants collected by one of my sons in 1916, and in after years by myself in the abandoned trenches on the hills overlooking Lake Doiran in Macedonia. Originally I had the three colours of this variety, a soft slaty-blue, a yellow, and a claret. I appear to have lost the two former, and the illustration represents the remaining claret-coloured form. The feature of the flower is its beard of closely-set, white hairs, tipped with dark blue; these stand out conspicuously on a shapely, reflexed fall. True to the type, it has practically no stem, and a long perianth tube. The spathes are almost membranous and papery; in the early stage of growth the leaves of my "pumilas," as they push up from the rhizome, are scimitar-shaped, but, after the flowering period, lose their original shape and develop an upward growth, increasing in size until they attain a height of seven or eight inches. When the seed capsules are ripe they are to be found sessile among the leaves, as Mr. Dykes pointed out when he discovered a seed-pod sitting on the ground at the base of the leaves in a plant which I had crossed with an I. germanica variety. In my former garden, only fifty feet above sea-level, I was more successful growing it out-of-doors than I am here at an altitude of 450 feet.

This Iris has afforded me another interest. It was the means of introducing a variety of Anemone blanda which has given me great pleasure, when in the early days of the year our gardens are wanting in colour. At the base of one of the rhizomes sent home in 1916 by my son, when this Iris shed its leaves on the approach of winter, I discovered a small Anemone corm wedged between two rhizomes. It was detached, carefully nursed, and when it grew to be about three inches across, I cut it into pieces, each with an eye. In that way my stock was increased, and all friends who have it, pronounce it meritorious. It blooms in various places in the garden, from early March to the end of May.

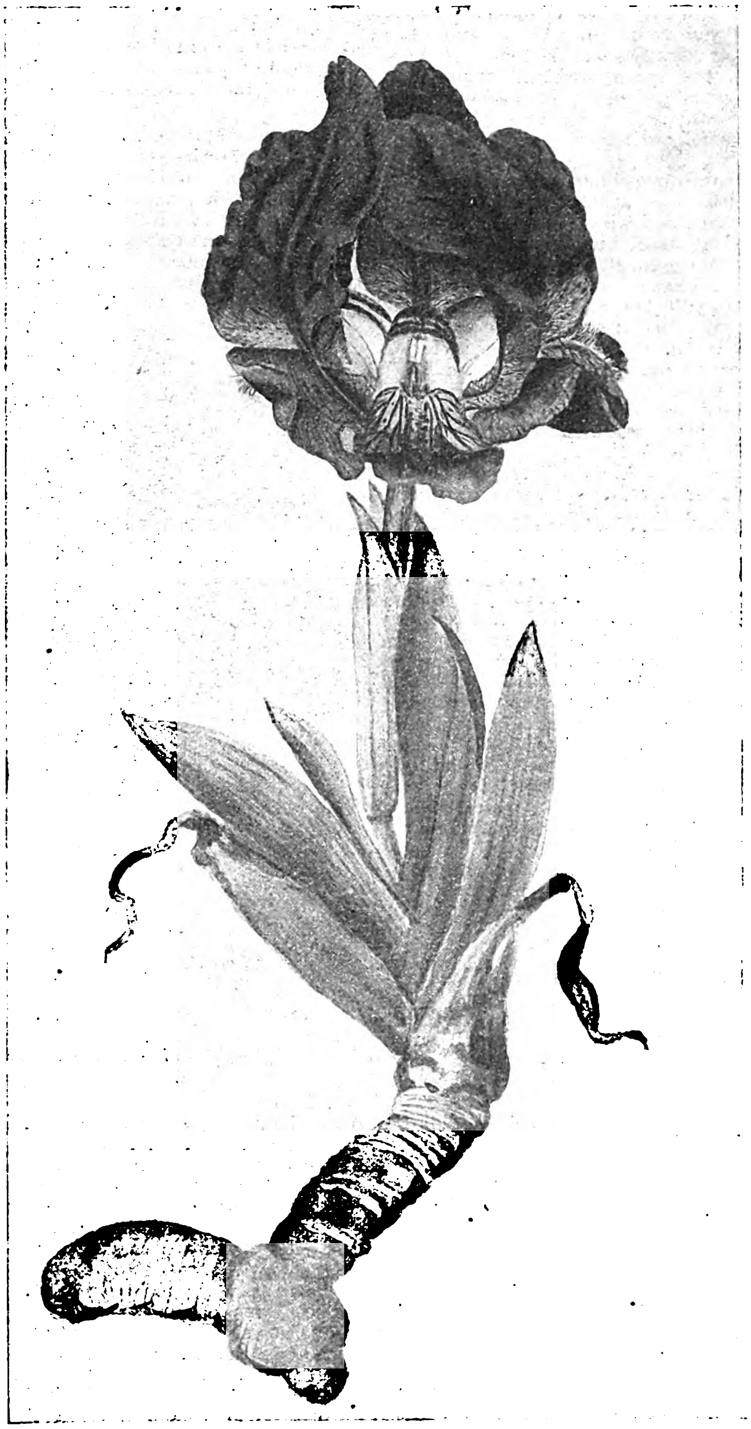


FIG. 216.—IRIS PUMILA FROM MACEDONIA.

Iris p. var. attica is another of the small type of this species collected on Hymettus, near Athens, and also on the island of Salamis in the Bay of Eleusis, off the entrance to the Piraeus. I was advised to go there for this Iris; so, taking advantage of several hours before the departure of my steamer for Trieste, I visited the quay in the Piraeus early one morning, expecting to find it an easy matter to engage a boatman willing to take me to the island. Boatmen and sailing boats were there in numbers, but none were forthcoming for such a trip. At last, a bargain was struck with a young fellow and his partner, owners of a rowing boat. Once out of the harbour he confided to my interpreter that he was a refugee from Constantinople, which explained why he had been ready to venture a journey which the ordinary boatman considered too hazardous. We landed on a narrow point in that part of the island known as the "Cynosura" (dog's tail) where, amid a very rocky surface, this variety attica had been flowering in profusion; the blooms are white, with a mixture of violet, and have all the characteristics of the type.

Living as it does at sea-level, I find it short-lived out-of-doors; on the other hand, the same Iris from an altitude of 2,000 to 3,000 feet on Hymettus, may have a better constitution. In this part of England, the only hope of keeping my plants alive is to grow them in frames. I have been astounded to see the successes of this dwarf "pumila" in Sir William Lawrence's garden, planted at the foot of the wall in the hottest part of the garden; but more astonishing still is the success attained by Dr.

Guiseppe, in Felixstowe, where he grows and multiplies this Iris on the edge of a well-drained peat bed which may receive a flow of water when needed from a moraine on a higher level.

IRIS MELLITA.

Fig. 215 represents I. mellita, another dwarf "pumila" which has come my way, collected on Ahlem Dagh, a hill inland a few miles from the Bosphorus on the Asiatic side. I have also the same form from the deserted island of Andreas, in the Sea of Marmora. Here we have a pumila with firm and rigid spathes. As in I. pumila, the stem is practically non-existent. It has sharp keels to the spathes which enclose the buds. The flowers are mostly of a smoky and dirty yellow, although sometimes one may come across a smoky shade of purple or claret, or a mauve form.

Iris m. var. rubro-marginata is stated to have come from Scutari, opposite Constantinople. I have not collected this variety, although I have many times been there, but I have it in my collection and find that of all the "pumilas" of the Balkan peninsula it has the soundest constitution. It is easy to cultivate and flowers readily. The young leaves, and particularly the spathes, are edged with red, but otherwise this form differs in no way from the typical example of the species. Because of its hardiness, I sometimes wonder whether the country of origin of I. m. var. rubro-marginata has not been confounded with the Scutari of Albania.

It will be observed that the foregoing notes on the "pumila" Irises have reference to those sorts which belong to the southern area of their distribution. Those from the northern area are larger and sounder in constitution. I have several of the pumila group grown by the late W. R. Dykes which came from the northern area, all typical examples, with their long perianth tubes and scarcely any stems; they are all good-natured, increase readily, and are very floriferous. If we compare the three Irises illustrated on Plate XXXII in Dykes' *The Genus Iris*, with the life-size illustrations (Figs. 215 and 216), which accompany these notes, it will be seen that those from the southern area of distribution are the smaller, and I am, therefore, of opinion that it is because they come from warmer climes that they are less likely to withstand the climate of Kent at an altitude of 450 feet.

They appear to me to come between the very dwarf pumila and the Chamaeiris groups.

IRIS REICHENBACHII.

This is figured in *The Genus Iris*, Plate XXXIV, and has many synonyms. It has sharp keels to the spathes which enclose the buds. Here the stems are six to ten inches long, with relatively short tubes, only one-and-a-half inch long. This form was collected by me on the slopes of Mount Olympus, Thessaly, at an altitude of 3,000 to 3,500 feet. My plants were of the yellow form, with a tinge of green at the base of the segments. I find the climate of Sevenoaks very unsuitable for this Iris, with the result that I now give the plants frame protection in the winter.

THE GERMANICA GROUP.

In my wanderings, I have come across several varieties among the tall-growing species. I will take, to begin with, the commonest of all Irises, the so-called I. germanica, of which Kharput is a fair example, named originally by Sir Michael Foster after a town in Armenia from which he received plants. In 1907 I collected plants in Kashmir, and in more recent years I received rhizomes from Kirman, in South Persia, which, on flowering, prove, so far as I can judge, to be the same as Kharput, and are strongly scented. As I write, both varieties in my garden are throwing up their bloom stems, and to all appearance are identical. Recently, in the high Atlas, Morocco, as we passed through villages above an altitude of 6,500 feet, the terraces under cultivation were all edged on the outer retaining walls with a dark blue Iris which I took to be another Kharput. I got, however, an impression that the dark violets were of a redder tone of violet, which may have been due to the brilliancy of the atmosphere as compared to our English climate. As my party mounted higher and out of reach of villages and cultivation, again we came upon patches of the same plant, and so it continued to perhaps a mile beyond the last village, Tachdirt, 7,500 feet, in the valley, and within one-and-a-half hour of the pass, Tizi Itbirani, on the divide of the main Atlas range. The slopes on the opposite side of the valley facing north were snow-clad.

Under such circumstances we may surely surmise that such a plant is indigenous to the soil; but then I am reminded that the vitality of the Iris rhizome is such that it will grow in almost any position, and withstand journeys that are almost invariably fatal to more slender plants.

Hooker and Ball visited this country in 1871, after the flowering season; they collected the plant and classed it as a germanica, but the question which puzzles me is how came these plants on the bare hills of Morocco; were they escapes from the cultivated areas, or were they originally introduced from some such country as Arabia, by pilgrims visiting Mecca? This is the usual theory, to which is added the belief that the white-flowered varieties were commonly planted on graves. This custom I can appreciate in some Mohammedan countries, but here in the high Atlas, among the Berbers of the hills, their cemeteries are of the meanest, without any vestige of head-stone or plant adornment. Their religion is no better, and I cannot believe that such people as I saw ever made pilgrimages to Mecca. The very wide distribution of this Iris forms a very puzzling subject.

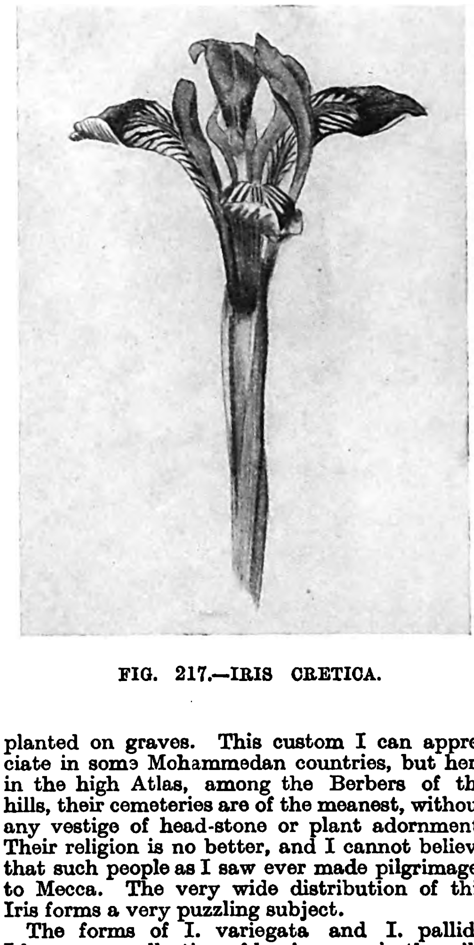

FIG. 217.—IRIS CRETICA.

The forms of I. variegata and I. pallida I have no recollection of having seen in the wild state; on the other hand, I. albicans, I. germanica, and I. florentina I have collected in many places far and wide, including a white form of I. germanica which lives in Crete, where, in an open, wild country, a large colony was luxuriating in the shade of the branches of a Plane tree, having as a background Styrax officinale. On one occasion, in the south of Crete, I happened to be staying the night in a native hostel, and learning that the Bishop of the diocese resided near by, I felt it my duty to call upon his Holiness. I was graciously received with the usual offering of raki, and loocoom, washed down with water. I was asked what brought me to Crete, and when told that I was plant hunting, I was immediately taken into the Bishop's garden, where, among other plants, under the broken shade of fruit trees, I beheld a mass of upright Irises in full bloom and in perfect condition. They were of the variety Cypriana, and measured five-feet four-inches in height, with stout and rigid stems needing no support. I thought of my friend George Yeld, the raiser of Asia, a beautiful, sweetly-scented Iris of Trojana parentage with branching stems, but weak in the legs. I took away rhizomes but, as with I. mesopotamica, another of the Palestine Pogoniris, they have failed to produce flowers. Not so a form of I. Ricardi sent to me from Tarsus, which has behaved itself, some years flowering very freely, although last year this was one of the varieties among several which failed me. Such are the chances of trying to grow species from hot countries.

I. kashmiriana, another germanica, and one which belongs to the Indian group of Pogoniris, was collected on this same journey. It was found growing near and among the ruins of the Sun temples of Martand (700 A.D.) in a sunny prospect commanding the finest view of the famous valley of Kashmir, and perhaps in the world—the "Paradise of the East, with its sacred streams and glens, its orchards and green fields, surrounded on all sides by vast snowy mountains whose lofty peaks seem to smile upon the beautiful valley below."

This is a very distinct Iris, but a bad doer in this country owing to some weakness in its constitution. Some seasons I have flowered it, when, as we know, it has milk-white flowers, with some slight purple markings on the blade of the falls, and exceptional fragrance. It has a tendency to increase its growth of rhizome, without any corresponding root increase, and after a few years peters out. Foster got it to seed, and raised plants, one of which came to be known as Foster's Kashmir White, and is still in the front rank of white Irises.

IRIS UNGUICULARIS.

I. cretica is a variety of I. unguicularis, and my introduction to this very choice gem came about in an odd manner. I was mounted on a mule, travelling upwards in the early stages of an ascent on Ida, in Crete. As I rode along, following a leader, always intent on looking out for plants, I suddenly found myself entangled in the branches of a tree which unseated me. I fell into a tussocky clump of what appeared to be a coarse grass, and then discovered to my intense delight the flowers of a small Iris, which turned out to be no other than the Cretan variety of I. unguicularis. Later on, I came upon many more plants, invariably growing in sheltered places at an approximate altitude of 2,000 to 3,000 feet.

The illustration (Fig. 217) is from one of my Cretan plants, which has been out-of-doors all the winter; its flowers are splashes of several shades of rich Burgundy wine-red on a white ground, with orange at the base of the falls and beard. The leaves are glaucous, of a leathery texture, a tenth-of-an-inch wide at the base, and tapering to sharp points at the tips. There are two sizes, from six to ten inches high. Although I had some few blooms this spring, my clumps were badly punished by the severity of the winter, and I feel sure that I shall only save this variety by frame protection.

In concluding this note, I would like to state how very aggravating plant-hunting on horseback is. The eye is carried forward with the motion of the animal. Many small objects are too imperfectly seen to convey a definite image. To dismount is often to no purpose, and stops the cavalcade, and so it comes about than many an interesting plant may be missed altogether; but, apart from the handicap of this method of plant-hunting, one may readily mistake the grass-like growth of this Iris for coarse Knot Grass. Hiatt Baker, who was with me in Crete in 1926, thought so until he found a seed-pod sitting almost on the soil at the base of a stem.

APOGON IRISES.

I. spuria, I. aurea and I. ensata, all three belonging to the Apogon section, were among my finds on the occasion of my visit to Kashmir. They all survived removal to England, which I regard to-day as remarkable since experience has taught me that they resent transplantation.

I. spuria figures in *The Genus Iris*, Plate xv, and grows to a height of four feet, and to all appearance is similar to the European form of I. maritima, found in the marshes near Hyères. I. aurea (Plate xvi), is a gorgeous deep yellow form which I have always grown with great success. The interest to me of this plant is, that in 1911 I received seeds of an Iris from Teheran which, on flowering, turned out to be I. aurea, both lots flowering on the same day, although natives of countries very far apart. I. ensata is a form, Dykes wrote, of wide Asiatic distribution from the Altai region to Shantung and Corea. In Kashmir the foliage is used as fodder, while in the neighbourhood of Kashgar it is woven into cord, and bunches of vegetables and of Grapes are mostly tied with it. I am reminded by Mr. Yeld of I. notha, another Asiatic form of I. spuria we found by the acre (in seed) on our way from the Evlak station on the Baku railway to the town of Nucha, which was our starting point for a mountaineering expedition into Daghestan in 1890. Professor Michael Foster raised plants from it, and Mr. Yeld stocked the Messrs. Backhouse nursery with seedlings.

I will close my notes with I. Sintenisii, Plate xvii, in *The Genus Iris*, regarded by Mr. Dykes as the I. spuria of the Balkans. It crosses the Bosphorus where, on the Giant's mountain, I collected plants many years ago. Again, in Ahlem Dagh, where in the month of May or June in 1925, the "maquis" of the hill was ablaze with red, white and blue flowers; the red and white were Cistuses, and the blue this variety of Iris. There are two sizes, nine to sixteen inches high, and they are very useful plants in a rockery, filling up the interstices of rocks with a mass of narrow, linear, dark green, shiny leaves over which appear brilliant, deep blue-purple flowers. They are very deep-rooted and very tenacious, and resent transplanting; their seed capsules add a feature to the winter clothing of a rockery, for they seed freely, but, like the small Sisyrinchiums, are inclined to be a nuisance to neighbouring plants. *G. P. Baker, Sevenoaks.*

TALL BEARDED IRISES FOR THE SPECIALIST.

THE tall, bearded or June-flowering Irises are notably plants of easy culture and not exacting in the matter of special treatment; and as such, the section has claimed, and is claiming more and more at the present time, the attention of garden lovers.

As in all other branches of horticulture, however, the hybridist is taking an increasingly important part, and in the search for flowers of large size, produced on tall, branching stems, an element of instability has been introduced into the race of tall, bearded Irises. Hence, we occasionally hear nowadays, that certain of the June-flowering Irises are not hardy, and this is generally associated in the minds of enthusiasts with the name of Iris Ricardi.

That there is a certain amount of truth underlying such statements cannot be denied, but a clearer understanding of the circumstances under which they have arisen, should do much to allay the fears of Iris enthusiasts.

It was not until about the year 1890 that a marked improvement in the types of June-flowering Irises began to show itself, and this may be attributed to the activities of the late Sir Michael Foster who, about that time, began to produce Irises of tall, branching habit, which were the result of the use, in hybridising, of an Iris which he received in 1888 from Cyprus, and which he called I. cypriana. This Iris, when crossed with I. pallida, produced such varieties as Caterina, Shelford Chieftain and Lady Foster, all of which made history in their time, and marked quite a new departure in tall, bearded Irises.

I. trojana arrived from the Troad in the year 1887 and, being a plant producing a tall, candelabra-like flower spike, at once recommended itself to the hybridist; this was much used, as was also I. Amas (syn. macrantha) in the production of taller and larger-flowered garden Irises. Such well-known raisers as Mr. Yeld and Sir Arthur Hort in this country, and firms like M.M. Vilmorin-Andrieux et Cie., in France, continued to use these three Irises (viz. cypriana, trojana and Amas) for many years in the production of new varieties, many of outstanding merit, and the question of hardiness never arose.

About the year 1912, however, a French amateur, namely Mons. Denis, introduced some particularly fine Irises, which he had obtained by the use in hybridising of I. Ricardi. This Iris was sent to Mons. Denis by a friend living at Avignon (M. Richard) who had received it from near Jerusalem, and after whom it was named. M. Denis sent a piece of this Iris to Sir Michael Foster, who named it Iris cypriana var. Ricardi. There is considerable confusion surrounding this Iris, but the long flexuous flower-stalk and big, straggly flowers seem to be common to both Iris Ricardi and I. cypriana. The late Mr. Dykes, however, considered it as probably a form of I. mesopotamica, which is found in Armenia.

M. Denis, who lived on the Mediterranean, near Marseilles, at that time, was well located to grow this Iris satisfactorily, but his beautiful hybrids, now in commerce, do not, as a whole, do themselves justice in our wet climate. As a native of the east, it is clear that I. Ricardi must have really hot summers, and it cannot be considered a "hardy" Iris in this country.

The best-known of the earlier Ricardi strain of Irises of M. Denis are:—Mdlle. Schwartz, M. Brun, Menetrier, Madame Durrand, J. B. Dumas, M. Cornuault, Leverrier, Gernez, Jussieu and M. Hubert. Given a warm, sunny position, many of these Irises will flourish in our English gardens, but they cannot be strictly classified as "garden" Irises, but rather as Irises which require special culture. In America, and particularly in California, a variety of I. Ricardi, called mesopotamica, has been used largely (notably by the late Mr. Wm. Mohr), and the resultant hybrids are quite outstanding for size of bloom and stately carriage, but these varieties, again, are not found hardy as a general rule in the eastern States of America, nor in England.

Succeeding generations of these very fine Irises will surely eventually cast off this tendency to tenderness inherited from their eastern ancestors, and when this has taken place we shall have still larger-flowered and taller-stalked Irises for the back of our Iris borders, than we have to-day.

In the meantime, however, we must be content to accept these semi-hardy Irises as steps in the ladder of progress, but, nevertheless, well deserving of culture by the "specialist." Those who would experiment with them must be prepared to afford them protection from rain (nothing else) through the winter months—it is impossible to choose too dry a position—and they will then be rewarded by flower spikes which will make walking sticks for their children, and be afforded the satisfaction of having grown successfully Irises which their neighbours have probably failed with! *G. L. Pilkington, Hon. Secretary, The Iris Society.*

IRISES OF THE BRUNO TYPE.

IRISES, especially the tall, bearded varieties, have always been a feature of the hardy garden in early June. Coming between the May-flowering Tulips and the Roses, they fill a great gap and are very welcome. The increased interest taken in them during recent years is mainly due to the introduction of so many fine new sorts. For this we are greatly indebted to that great raiser, Mr. A. J. Bliss. At the Wisley trials in 1915 I noticed many outstanding new varieties of his raising, and a year or so later I visited his garden, and subsequently introduced many of his seedlings. It is a remarkable fact that, working on the lines only of the older forms, he had succeeded in introducing a large number of outstanding varieties, particularly Dominion. This is his most notable seedling, and it stood out from all others—an epoch-making plant—stated to be a seedling obtained from Cordelia crossed with Amas, but so far in advance of its parents as to be a clear jump ahead. The remarkable quality of Dominion was such that I described it as the finest Iris I have seen and, even then, in 1917, at the hitherto unheard price of £5 5s. 0d., it was distributed widely, especially in America.

The coloured illustration given with this issue conveys the beauty and form of Bruno more accurately than words can express. It was in the summer of 1919—a few years later—that I first saw in Bliss's garden the seedlings of Dominion, that are now spoken of as the Dominion race—Dominion hybridised with another undisclosed variety, producing Bruno, Cardinal, Majestic, Glamour, Moa, Conchobar, etc., while another Dominion cross produced Titan, Tenebrae, Swazi and Duke of Bedford—a wonderful family. As much as Dominion was in advance of its parents so, again, Bruno and Cardinal were in advance of Dominion. Those who saw Bruno as exhibited by Mr. Geoffrey Pilkington at the last Iris show, will readily accord it a high place as one of the six finest Irises in cultivation. The size and breadth of its fall are remarkable, while the velvety texture is equally good. Bruno has one slight fault, namely, the standards are somewhat thin. This has been remedied in one of its daughters, Mrs. Valerie West, which is, in the opinion of some growers, superior.

I have a large number of seedlings from Bruno crossed with Ambassadeur and other fine types, and the coming weeks will provide a busy time as they open day by day. The plants of the Bruno type show great vigour, with very broad foliage and large flowers. The stems are very rigid and firmly held. Dominion's flowers were rather close to the stem. This is one fault that has been remedied in its children. To all who care for Iris breeding and the raising of new varieties, Bruno is the parent par excellence, and apart from that it is a plant of fine garden beauty. Mr. W. Cuthbertson has grown it magnificently in his garden near Edinburgh, and far exceeding what we can do in the south here.

All Irises of the Dominion and Bruno type require a sunny position, and soil that is warm, over good drainage. The rhizomes are so large that, unless thoroughly ripened, the central flowering growth is apt to decay, therefore they cannot have too much roasting. *Robt. W. Wallace, Tunbridge Wells.*

TWO EARLY-FLOWERING IRISES.

IRIS verna, a dwarf species from America, is somewhat similar in appearance to I. chamaeiris, forming masses of green leaves about five inches high. During the first weeks of May, on stems little higher than the leaves, the gay flowers unfold; they are of brightest violet-blue, the standards and the falls being of the same colour. There are no bearded Iris species in America, and yet this diminutive plant does attempt to possess one—albeit a poor attempt—just a narrow band of pubescence, of richest orange, down the centre of the falls, contrasting well, however, with the bright tint of the flowers themselves.

Although coming from southern climes—it is a native of the country south of the Alleghany Mountains, from Virginia to Alabama—this plant prefers the cooler exposures of the rock garden, or thin woodland (not directly under trees), where it will flourish in well-drained sandy soil to which has been added peat and broken crocks or sandstone. It does not require lime, and probably derives much benefit from a pane of glass placed over it during autumn and winter.

Iris Albertii is an important plant belonging to the Pogoniris section of bearded Irises. Some results of crossing it with other varieties may be seen in a few of the newer, early-flowering "pallidas." Although it bears, perhaps, some relation to I. imbricata, it may easily be distinguished by the green spathes, which are rounded, and not keeled as in I. imbricata.

So early as the end of April, the sturdy stems, about two feet in height, reach up above the sword-shaped, glaucous-green leaves and display their several flowers of peculiarly soft colouring, which varies in different forms from pale lavender to greyish-yellow, and is somewhat reminiscent of the richer coloured, late-flowering variety Sunset. The flowers are finely veined with dark brown and mauve, and tinted and softened with intermediate shades. The veining ceases abruptly across the middle of the falls about on a level with the base of the beard, which is pale and greyish, and tipped with gold.

I. Albertii is a native of northern Turkestan. A warm, well-drained position, where the sun will thoroughly ripen the fat, grey rhizomes, is necessary to grow and flower it successfully. All things considered, August and September are the best months in which to divide and transplant it. It should be remembered that these species, and indeed all rhizomatous Irises, do not like their rhizomes to be covered with soil.

Iris Albertii is not common in gardens, perhaps on account of its somewhat peculiar colouring, but it is worth growing if only for its valuable early-flowering properties. *G. S. Thomas, Cambridge.*

THE FUTURE OF THE IRIS.

In the few suggestions which I make here at the request of the Editor, I must disclaim any prophetic gift. I have no desire to win the epithets so commonly bestowed on the unveracity of prophets in general. Still, looking back for forty or fifty years and recalling the work of our captain, guide and friend, Sir Michael Foster, not to mention others who have devoted their time and skill to making better what was already good, one may concede one's imagination a loose rein for a short space.

Our dwarf, bearded Irises call out for brighter colours. Will not some enthusiast devote himself or herself to their improvement? Notwithstanding Mr. Caparne's fruitful labours, there is still work to be done with the intermediates, as was indicated by the appearance of Messrs. Murrell's Sunbeam and Moonbeam last year at Chelsea. A clear pink, for example, is much to be desired.

Then we want plants which will not only blossom in spring, but also again in autumn, like Sir M. Foster's Mrs. Alan Gray. I have heard of one or two others but, unfortunately, I cannot recall their names. I. ochracea suggests that the flowering season may be prolonged. In fact, I believe efforts have already been made in this direction.

We want more self-whites and self-yellows. As the number of dark varieties is so rapidly increasing, more snowy and golden flowers are surely needed to set them off. I long to see a large, tall, shapely white, fit to stand beside our greatest coloured varieties. Indeed, self-coloured Irises generally are very desirable, and the ideal red has yet to appear.

Then there is the question of scent. Many of our present varieties are pleasantly scented, but one would like more of them to possess the fragrance of the white I. cashmiriana which once flowered to perfection in my friend Mr. G. P. Baker's garden at Bexley. Its fragrance was delightful, as was that of I. Bartonii (which Mr. W. R. Dykes considered to be a variety of I. cashmiriana). It once flowered in my York garden—a present from Sir M. Foster. I have never ceased to lament its loss. No scent of Rose or Violet or Viburnum surpasses it. It came originally, I believe, from a ditch at Kandahar.

The subsection 'Sibirica' grows so freely, and crosses so easily, that very careful selection is required among the seedlings, but plants like Perry's Blue, Emperor and Snow Queen are ornaments to any garden, and I look forward to others equally good.

If only an inexpensive method of growing them could be discovered, the Californian Irises, Santa Barbara, Los Angeles, etc., with which Mr. Pilkington delighted us last year, at the Iris Show, might lend an additional glory to the Iris grower's paradise. *G. Yeld, Orleton, Gerrards Cross.*

THE GENUS PRIMULA.

(*Continued from p.* 403.)

NEUROCALYX (Franch.). Woolly-leaved P.
(Malvacea.)

A PERENNIAL species with a tuft of foliage clothed with long, woolly hairs; the leaf blades are oval, from two to three inches across, blunt, heart-shaped at the base, borne on a hairy stalk somewhat longer than the blade; margins sinuately toothed; upper surface clothed with short, woolly hairs, underside more densely clothed with longer hairs. Flower stem four to six inches tall, bearing two or more superposed umbels of few, purple blooms. Corolla about three-eighths-of-an-inch across, divided into five heart-shaped, shallowly bilobed segments; tube cylindrical, about as long as the calyx.

Grows in shady places on the margins of thickets, etc., on the Tsinling Mountains, in Shensi, central China.

Culture: As for P. malvacea.

NINGUIDA (W. W. Sm.). Niveous P.
(Nivales.)

A handsome, somewhat robust perennial species with a stout rootstock clothed with long, fleshy scales densely covered with white meal. The leaves, which are hardly mature when the flowers expand, have broadly lance-shaped, rather pointed blades from three to four inches long, gradually tapering at the base into a broad stalk; margins edged with regular, rounded teeth; both surfaces green but covered with minute, meal-producing, glandular hairs; underside coated with white meal when young. Flower stem robust, about six inches tall, sparsely mealy at the tip, bearing an umbel of three to fifteen rich purple blossoms with a small, dull orange eye. Corolla about one inch across, with nearly elliptic, blunt, entire lobes; tube cylindrical, about half-an-inch long, with a ring in the throat. Flowers in June.

Grows on alpine moorland among dwarf, scattered Rhododendrons, etc., in south-eastern Tibet, at 14,000 to 15,000 feet above sea-level.

Culture: Grow it in good fibrous loam, peat and leaf-soil, in a well-drained, half-shady spot, kept moderately damp in summer.

NIPPONICA (Yatabe). Nippon P.
(Cuneifolia.)

This attractive, dwarf perennial is a sub-species of P. cuneifolia (Ledeb.); it forms a tuft of more or less erect, oblong-spathulate or lance-shaped-spathulate, pointed leaves, one to one-and-a-half inch long, gradually or abruptly tapering to a winged stalk exceeding the blade in length; margins edged with two or three comparatively large, sharp, saw-like teeth; both surfaces more or less mealy, or quite smooth. Flower stem two to five inches tall, slender, flexuous, bearing an umbel of two to five nodding, pure white blossoms. Corolla slightly concave, from five-eighths- to nearly one inch across, divided into five heart-shaped, deeply notched segments rounded at the tip; tube cylindrical below, dilated upwards, about a quarter-of-an-inch long. Flowers in May and June. In cultivation in 1916. (Illustrated in *Notes from the Royal Botanic Garden, Edinburgh,* 1913.)

Grows in damp, rocky mountain pastures in central Japan.

Culture: Good gritty, fibrous loam, in a fairly moist, open spot, should suit it.

NIVALIS (Pall.). Snowy-flowered P.
(Nivales.)

The type of this very beautiful perennial species forms a tuft of oval-oblong or lance-shaped, blunt or rather pointed leaves three to five inches long, tapering to a winged stalk; margins recurved and furnished with blunt teeth, or at times nearly entire; both surfaces more or less smooth. Flower stem stout, four to ten inches tall, bearing one, rarely two, many-flowered umbels of lovely white blossoms. Corolla three-quarters- to one-and-a-quarter inch across, divided into five broadly heart-shaped lobes; tube cylindrical, about twice as long as the calyx. Flowers in June and July.

Grows in damp mountain meadows and on the banks of alpine streams, frequently at considerable elevations above sea-level, on the mountains of many parts of central Asia. Introduced in 1790.

Var. farinosa (Schrenk.). This form is smaller than the type, with coarsely-toothed, elliptic-oblong, rarely entire leaves; underside more or less mealy; margins densely so. Flowers purple, in one or more superposed umbels. Turkestan and the Altai.

Var. sinensis (Pax.). A robust form with entire leaves, densely coated with yellow meal beneath; flowers purple, in superposed umbels. Yunnan, western China, at about 12,000 feet.

Culture: Rich, well-drained loam and peat in an open spot, well supplied with water when the plants are in growth, with protection from wet in winter, are the conditions indicated.

NUTANS (Delavay). Nodding P.
(Soldanelloidae.)

A biennial, in as much as it invariably perishes after flowering. Leaves two-and-a-half to seven inches long, with narrowly elliptic, or broadly lanceolate, somewhat blunt blades, tapering gradually to a broadly winged stalk; margins toothed; both surfaces covered with fine hairs. Flower stems nine to twenty-four inches tall, erect, rather slender, covered with white meal in the upper half and among the blossoms. Produces a crowded umbel or spike one-and-a-half to two inches long, of six to twelve nodding, stalkless, very fragrant blossoms. Corolla three-quarters-of-an-inch to one inch across, lavender-blue to violet, bell- or funnel-shaped, divided into five oval or rounded, concave segments with three very fine teeth at the tip of each; tube funnel-shaped, three-quarters-of-an-inch long, mealy on the outside. Flowers in September and October. Introduced in 1915. (*Gard. Chron.,* May 26, 1928, Fig. 178).

This species grows in, and on the margins of, thin woods, especially in Pine forests, usually in situations sheltered from strong winds and open to the sun, on the mountains of northern Yunnan and south-western Szechuan, at considerable elevations above sea-level.

Culture: Plant it in leaf soil and light loam, in a sheltered, half-shady spot.

OBCONICA (Hance). Ichang P.
(Obconica.)

This handsome species is the parent of numerous beautiful florists' Primulas so popular for greenhouse and window decoration. The true plant is a tufted, deciduous perennial, with a rather stout rhizome which produces short stolons, and these end in tufts of foliage which form new plants. The leaves vary in shape from elliptic to oblong and oval; they are rounded or heart-shaped and measure one to four inches in length; the margins are slightly undulate and have small or large, blunt lobes which are always finely toothed; they are borne on rather stout, hairy stalks one to six inches long; both surfaces glaucous and covered with fine hairs. Flower stem fairly stout, hairy, four to eight inches tall, bearing an umbel of six to twenty lilac or purple blossoms with a pale eye, on stalks half-an-inch to one inch long. Corolla one to one-and-a-quarter inch across, divided into five broadly heart-shaped, shallowly bilobed segments; tube cylindrical, slightly dilated upwards, with an indistinct ring in the mouth. Introduced in 1880.

Grows on rocks in vegetable debris in the Ichang Gorge, Hupeh, central China.

Culture: Grow it in a compost of leaf-soil, loam and limestone chips, and treat as a greenhouse plant; some of the garden forms have been grown successfully in the open air in southern and western England.

OBLIQUA (W. W. Sm.). Oblique-flowered P.
(Nivales.)

A beautiful, deciduous perennial species of robust habit with a large tuft of somewhat leathery leaves, springing from fleshy resting buds, with leaf-like blades three-quarters-of-an-inch to two inches long. The true leaves have narrowly lance-shaped, blunt or somewhat sharp tips, and gradually taper to a winged stalk, with a membranous sheath at the base, in all from three to five inches long; margins edged with sharp teeth; upper surface more or less smooth, underside mealy. Flower stem stout, twelve to eighteen inches tall, bearing an umbel of about half-a-dozen slightly nodding, delicately fragrant, pale yellow, pale flesh-pink or almost white blossoms, thick and velvety in substance. Corolla oblique or irregular, about one inch across, with rounded, notched lobes; tube cylindrical below, funnel-shaped upwards, about three-quarters-of-an-inch long. In cultition in 1920.

Grows in the shade of dwarf Rhododendrons, etc., on the Singalela and Chola Ranges, in the eastern Himalayas, at about 12,000 feet above sea-level.

Culture: Good friable loam and leaf-soil, in a cool, shady spot, should suit it.

OBOVATA (Pax). Obovate-leaved P.
(Carolinella.)

A dwarf, perennial species with a tuft of firm, papery leaves with oblong-egg-shaped or egg-shaped, blunt, frequently retuse blades, wedge-shaped at the base, in all three to five inches long; margins furnished with obscure, blunt or thickened teeth; both surfaces more or less smooth. Flower stem slender, three to five inches tall, bearing a short, umbel-like raceme of rose-coloured blossoms. Corolla about half-an-inch across, divided into five broadly heart-shaped, bilobed segments; tube slender, cylindrical, slightly dilated upwards. (*Bot. Mag.*, t. 6,712.)

Grows in damp places on the mountains south-west of Mengtze, in south-eastern Yunnan, western China.

Culture: As for P. megaseaefolia.

OBTUSIFOLIA (Royle). Blunt-leaved P.
(Obtusifolia.)

A handsome, deciduous perennial species with a stout rootstock and usually mealy resting buds. The rich green leaves, in tufts, are from two to six inches in length and vary in shape from elliptic-spathulate, to egg-shaped or oval, pointed or blunt at the tip, narrowed, rounded or heart-shaped at the base, with a distinct, winged stalk; margins entire or furnished with coarse, blunt or sharp, irregular or regular teeth; both surfaces more or less smooth, or underside covered with yellow meal. Flower stem stout, six to ten inches tall, bearing an umbel of four to fifteen bright bluish-purple blossoms on slender stalks. Corolla three-quarters-of-an-inch to one inch across, flat, with broadly heart-shaped lobes. (Royle, in *Illus. Bot. Him.*, 1839, t. 77, Fig. 1.).

Grows in moderately damp, shady spots in rocky soil in the north-western Himalayas at 10,000 to 14,000 feet above sea-level.

Culture: Good friable loam, in a cool, half-shady spot, is indicated.

ODONTOCALYX (Pax). Haopin P.
(Petiolaris-Sonchifolia.)

An apparently desirable perennial species with a tuft of smooth, non-mealy, membranous leaves about two inches long and one inch wide, with oblong, blunt blades, almost stalkless or gradually tapering to short, winged stalks; margins furnished with irregular teeth as though gnawed by insects. Flower stem stout, about two to three inches tall, bearing a terminal umbel of many blossoms the colour of which has not been recorded, but is probably some shade of purple. Calyx cup-shaped, with broadly oval lobes, each with two to three teeth at the tip. Corolla about one inch across, with broadly heart-shaped, nearly entire or toothed lobes. Not in cultivation.

Grows on the Tsinling Mountains, in the province of Shensi, central China, at about 4,500 feet above sea-level.

Culture: Good friable loam, peat and leaf-soil, in a cool, half-shady spot, is indicated.

OENENSIS (Thomas). White-throated P.
(Auricula-Erythrodrosum.)

A beautiful European perennial species of tufted habit with oblong-wedge-shaped or lance-shaped-wedge-shaped, blunt or truncate, distinctly stalked leaves one to three inches long; margins furnished with sharp teeth toward the tip; both surfaces densely clothed with reddish, viscid, glandular hairs. Flower stem three to four inches tall, bearing a two- to seven-flowered umbel of soft rosy-mauve blossoms with a pure white throat. Corolla half- to three-quarters-of-an-inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical below, dilated upwards, glandular, about half-an-inch long. (Illustrated in *Journ. Roy. Hort. Soc.*, Vol. XXXIX, 1913.)

Grows on stony alpine slopes and clefts in limestone rocks in the west Rhaetian and Bergmasker Alps.

Culture: Plant it in good loam and grit, in an open, sunny spot well supplied with water when in growth; or it may be cultivated with success in a crevice in a limestone rock, packed with the above compost. *A. W. Darnell.*

(*To be continued*).

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Fritillaria karadaghensis.—Fritillaria karadaghensis flowered in the open ground here on March 20; out of six bulbs planted, four flowered, and one had two flowers on a stem. It was planted in an Iris bed fully exposed and with only a three-foot hedge of Lonicera nitida as a wind break. One plant has set seeds. *R. M. A. Keeble, Mottingsden, Burwash, Sussex.*

Difficulties of the Scottish Forestry Commissioners.—While welcoming the friendly intention of the note under this heading in your issue of May 25, I beg leave, as one of the Commissioners, to repudiate the statement that "the great difficulty is to make landowners' sentiment overcome their cupidity." The "great difficulty" is rather that in the hill land to which afforestation is necessarily limited, the proportion of plantable to unplantable land is in Scotland usually very low. Owners are naturally reluctant to part with the plantable and retain the unplantable, which, bereft of its wintering ceases to have any pastoral value. This obstacle in many cases necessitates the acquisition of whole estates. As regards denuded woodlands (which the Commission is prepared to take over, although this is not strictly speaking its job) the "great difficulty" is to make the owners' cupidity overcome his sentiment, since the Commission is prepared to pay a fair price for good areas which the owner cannot afford to replant, and which in their derelict state not only bring in no revenue, but entail some expenditure in taxation and supervision. A few owners have, perhaps, not altogether without reason, a horror of dealing with any government department, but the majority in Scotland, as in England, have met the Commission very fairly, and evinced a real wish to further its work. *John Stirling Maxwell, Pollokshaws.*

The Sweetest-scented Flower.—I would like to state, in reply to *R. Kemp* (p. 369), that I consider the Daphnes, particularly the greenhouse or half-hardy sorts, such as D. indica and D. rubra, should be placed first, for well-grown specimens of these, with from twelve to eighteen trusses of flowers, nearly all fully developed, are hard to surpass in the matter of fragrance. *Barrell, Wroxham Hall Gardens, Norfolk.*

A Fine Old Magnolia conspicua.—I send a snap-shot photograph of a large tree of Magnolia conspicua (Fig. 218) in the grounds of Norwood Court, belonging to the Lorival Manufacturing Co., Southall, Middlesex. So far as I have been able to ascertain, the house was built in 1770 for Josiah Wedgwood, so the Magnolia may be approximately one hundred years old. The tree is eighteen feet high and twenty feet wide, and the trunk has a girth of thirty-four inches at eighteen inches from the ground. I am told it is one of the finest specimens in the country, but no doubt some of your many readers may be able to state whether this is correct. *G. Naylor, Norwood Works, Southall.*

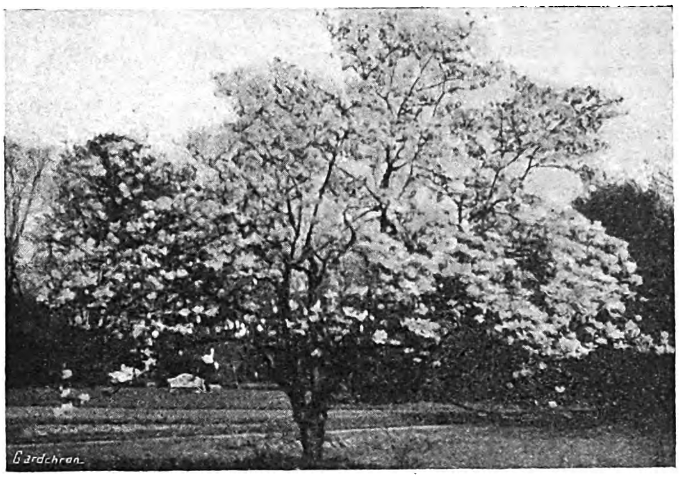

FIG. 218.—AN ANCIENT MAGNOLIA CONSPICUA AT SOUTHALL.

Apple Blossom destroyed.—Like *Market Grower* (p. 368, May 18), I find that the blossoms on my Bramley's Seedling Apples are absolutely killed, also on Lord Grosvenor and some trees of Lane's Prince Albert. These trees were loaded with fruit blossom and appeared to be all right up to a certain date. The same is also true of Raspberry Lloyd George; the canes of this variety are now killed to the ground. This is very disappointing after such good promise of fruit blossom. *W. A. Jenkins, Stockton-on-Tees.*

Herbaceous Calceolarias at Avory Hill, Eltham.—After reading Mr. Turner's article on "Herbaceous Calceolarias" (p. 400) a visit to the winter garden at Avory Hill, Eltham, would more than justify his remarks on this class of plants. I had the privilege of seeing a batch of these plants at Avory Hill last week, and am prepared to state that no finer wealth of colour and better grown specimens of these subjects could be seen in any establishment, and they reflect great credit on Mr. Parrott, the Superintendent, and his assistants. *A. Allen.*

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS.

One-hundred-and-eighty-nine candidates entered for the Senior Examination on March 20, 1929, and of these five were placed in Class 1, twenty-eight in Class 2, fifty-seven in Class 3, and eighty-three candidates failed. Sixteen candidates did not present themselves for examination.

A Silver-gilt Medal is awarded to Mr. Harold Fairbank, of Ivydene, Chapmore End, near Ware, Hertfordshire, who was placed first.

The bulk of the candidates, as usual, fall into two groups (1) those who have obviously had practical experience in horticulturre but have had little scientific training, and (2) those whose experience has been the reverse in both respects. A small proportion only of the candidates showed evidence of having seriously studied both sides of the subject, and of these a few did really well. On the whole, however, the level reached was not high.

The majority of candidates attempted Question 6, on the cultivation of a Vine under glass, and Question 9, on herbaceous plants, and answered them quite well. Very few candidates attempted Question 8, on the pruning of flowering shrubs, and many of those who did obviously had little or no knowledge of the subject. Answers to Question 7 were disappointing, the candidates not seeming to realise the importance of successional sowings of Brassicas. There were very few good answers to Question 10, on how to supplement the supplies of organic manure in the garden.

Forty-three candidates were examined in the Junior Section, and of these five were placed in Class 1, five in Class 2, nine in Class 3, and twenty-four candidates failed.

A Silver Medal is awarded to Mr. William A. Hughes, of Cheadle Royal Gardens, Manchester, who was first.

As in previous years, there was a great difference in the standard reached by the various candidates. There was a fair proportion of good answers, but, on the other hand, many were very poor, or even worthless. The chief general fault was the absence from the answers of helpful drawings. Hardy perennials confused a number of candidates, who could not distinguish between perennials, biennials and annuals.

SENIORS.

Class 1.—(1) Mr. Harold Fairbank, Ivydene, Chapmore End, near Ware. (2) Mr. Frederick John Reed, 30-32, Eastover, Bridgwater. (3) Mr. E. K. Lawrence, R.H.S. Gardens, Wisley, Ripley. (4) Miss M. L. Edwards, 111, Alma Street, Newport, Mon. (5) Mr. G. L. Knight, R.H.S. Gardens, Wisley.

Class 2.—(1) Miss I. M. Gover, Studley College, Warwickshire; and Miss M. A. Tracey, Aldersey Horticultural College, near Chester. (3) Mr. W. A. Dove, R.H.S. Gardens, Wisley; Miss K. M. Metcalf, Midland Agricultural and Dairy College, Sutton Bonington; and Miss C. M. Parry, 22, Quentin Road, S.E.13. (4) Miss E. A. Given, Aldersey Horticultural College; and Miss L. C. Style, Studley College. (8) Miss A. D. Lawrie, Aldersey Horticultural College. (9) Miss B. D. Latham, Studley College. (10) Mr. Percy E. Cross, John Innes Horticultural Institution, Merton; and Miss M. Jones, Bourne Lodge, Farnham, Surrey. (12) Miss Marion Lewis, Walmoor College, Chester; Miss M. Roscoe, 58, Redington Road, Hampstead, N.W.3; and Miss M. Glendinning, Studley College. (15) Mr. F. E. M. Praill, The Dell, Grange Street, St. Albans; and Mr. Harry Hall, John Innes Horticultural Institution. (17) Mr. A. G. Tunnard, R.H.S. Gardens, Wisley. (18) Mr. B. Douglas Shane, Farm Institute, Sparsholt, near Winchester; and Miss W. A. Duncan, Aldersey Horticultural College. (20) Mr. C. H. A. Robson, Wyndcliffe, Saffron Walden. (21) Miss D. M. Martin, Lady Gardener's Cottage, Bedgebury Cross, Goudhurst, Kent; Mr. Leslie P. Lee, 66, Selwyn Avenue, Kew Road, Richmond; Mr. R. E. Hardwick, R.H.S. Gardens, Wisley; and Mr. Harry Bone, Aylesbury Road, Wing, Leighton Buzzard. (25) Mr. Thomas Lomas, 79, Gladstone Road, Wimbledon; Mr. William Howell, 14, Riverside, Abbey Estate, Cambridge; and Miss I. M. I. Crane, Studley College. (28) Mr. John A. Haywood, Midland Agricultural and Dairy College.

Class 3.—(1) Mr. Bernard Hoyle, 108, High Street, West Melton, near Rotherham; Mr. F. A. Bush, Arddarroch Gardens, Garelochhead, Dumbartonshire; and Miss M. E. Morris, Ingoldisthorpe, King's Lynn. (4) Mr. W. R. N. B. Barnett, St. Patrick's Hall, Reading; Mr. George T. Goodship, Helford House, Drayton Road, Boreham Wood; Miss E. H. Parsons, Sturtmoor, Landford, Salisbury; Miss J. A. Buchanan, Studley College; and Mr. I. M. Burnet, R.H.S. Gardens, Wisley. (9) Mr. Harold A. Sanders, Wall Lane, near Lichfield; Mr. R. J. English, John Innes Horticultural Institution; Miss K. Barron, The Poplars, Boxmoor; Miss M. E. Woolger, 14, Radnor Avenue, Harrow; Mr. James W. Leggott, 19, Laurel Grove, Waterloo, Liverpool; Miss N. J. Gradon, Whitesmocks, Durham; and Mr. John L. Beddall, 4, Bennett Road, Crumpsall, Manchester. (16) Mr. William A. Hobday, Hopbine Cottage, Dormansland, Lingfield, Surrey. (17) Mr. Thomas Norman, Agricultural Institute, Usk, Mon.; Miss N. Hartley, Fir Trees, Stoke Green, Slough; Mr. John Roberts, Heaton Park, Manchester; Mr. Montague Carter, Colaton, Stone's Road, Epsom; Miss M. C. Johnston, Pye Corner Cottage, Broadway, Worcestershire; Miss M. James, Cheshire School of Agriculture, Reaseheath; and Miss M. Jones, Studley College. (24) Mr. W. E. Rickards, Arrowe Hall, Woodchurch, Birkenhead; and Mr. John N. Acaster, Cheshire School of Agriculture. (26) Miss D. H. Preen, Agricultural Institute, Usk; Miss M. B. Berry, Studley College; Mr. Ernest W. Brown, South Lodge, Elvetham, Hartley, Wintney; and Mr. R. A. Macdonald, R.H.S. Gardens, Wisley. (30) Mr. Frederick J. Marsh, The Lodge, Kites, Ramsden Heath, Billericay; Mr. F. S. Taylor, 25, Aspen Villas, Albert Terrace, Beverley; Mr. E. B. Horton, R.H.S. Gardens, Wisley; and Mr. J. R. Reid, R.H.S. Gardens, Wisley. (34) Mr. Joseph Pearce, The Gardens, Cottesbrooke, Northants; Mr. W. A. Tobias, Midland Agricultural and Dairy College, Sutton Bonington; and Mr. Albert V. Pike, The Gardens, Hethersett, Reigate. (37) Mr. Ross Young, Alexandra Park, Manchester; and Mr. Jack Hardy, 115, Corporation Road, Darlington. (39) Mr. John P. G. Page, The Hoo, Buckden, Hants.; Mr. John H. Lock, Alexandra Park, Manchester; Mr. George C. Searle, 5, Fenswood, Long Ashton, Bristol; Miss P. Askworth, Cheshire School of Agriculture, Reaseheath; and Miss G. Kershaw, Studley College. (44) Mr. John W. Norwood, 2, College Cottages, Hextable; Miss Vivien Graves, Walmoor College, Chester; Mr. John D. Douglas, Penninghame Gardens, Newton-Stewart, Wigtownshire; Miss S. H. Ironside, Studley College; Miss Rosemary May, Studley College; Mr. John W. Worrall, 154, Nottingham Road, Hill Top, Eastwood, Notts.; Mr. Lawrence Wass, Nether Hall Nursery, Dronfield, near Sheffield; and Mr. H. S. Boothman, R.H.S. Gardens, Wisley. (52) Mr. Cecil J. Callister, Ballaglonney Cottage, Crosby, Isle of Man; Mr. Charles W. West, 4, Rose Cottages, Beardall Street, Hucknall; and Mr. P. B. Platts, R.H.S. Gardens, Wisley. (55) Mr. G. W. G. Freeman, 11, Northfields, Twyford, Berks.; Miss J. Anderson, c/o W. Anderson, Esq., Mortimer; and Mr. James George, Reelig Lodge, Kirkhill, Inverness-shire.

JUNIORS.

Class 1.—(1) Mr. William A. Hughes, Cheadle Royal Gardens, Manchester. (2) Miss Z. F. Ford, Agricultural Institute, Usk, Mon. (3) Miss K. F. Heley, Hele, Valebridge Road, Burgess Hill. (4) Miss P. Chaplin, The University, Reading; and Miss W. M. Long, Conisborough, Rosebery Avenue, Linslade, Leighton Buzzard.

Class 2.—(1) Mr. G. R. Long, R.H.S. Gardens Wisley. (2) Mr. K. G. L. Rackett, The Farm Institute, Sparsholt, near Winchester. (3) Mr. D. A. Builder, R.H.S. Gardens, Wisley. (4) Mr. F. G. Goldsack, 32, Landport Street, Fratton, Portsmouth; and Mr. H. C. Haskins, R.H.S. Gardens, Wisley.

Class 3.—(1) Miss E. M. Chambers, The Farm Institute, Sparsholt; and Mr. K. C. Boorman, R.H.S. Gardens, Wisley. (3) Mr. S. C. Willson, R.H.S. Gardens, Wisley. (4) Mr. William Henry Butt, Agricultural Institute, Usk. (5) Mr. Charles William King, 42, Cassland Road, South Hackney, N.E. (6) Mr. G.N. Stallard, 155, Beardall Street, Hucknall, Notts.; and Mr. N. S. Flowers, R.H.S. Gardens, Wisley. (8) Miss M. E. Foster, 80, Polsloe Road, Exeter; and Mr. Henry C. Rudge, 24, Taylor Street, Nechells, Birmingham.

TEACHERS' EXAMINATION IN SCHOOL AND COTTAGE GARDENING.

Of the 296 candidates who entered on March 23, 108 were placed in the First Class, seventy-nine in the Second Class, forty-one in the Third Class, and twenty-seven candidates failed. Three candidates who failed omitted to answer the compulsory question. Forty-one candidates were absent.

A Silver-gilt Medal is awarded to Mr. Clarence Charles Quelch, of the School House, Gaunt's Common, Wimborne, who was first.

The answers to the Compulsory Question, asking for the cropping plan for one year for two poles which were to be allocated to two boys, were, on the whole, very good. Some of the answers showed distinct evidence of "cramming," particularly those to Question 5, dealing with Apples for a cottager's garden. Some of the answers to Question 3, on pruning, were excellent, showing a good knowledge, but a few candidates did not give much thought to the subject. Some of the answers showed a higher standard than in previous years, but a common fault was the incompleteness of the answers.

NURSERY NOTES.

MESSRS. BARR AND SONS.

Although our visit, a few weeks ago, occurred somewhat near the end of the Daffodil season, and rather too early for the Tulips, owing to the lateness of the season, yet there was much of interest to be seen at the Taplow nursery—on the Bath Road, near Maidenhead, and within easy distance of London—of Messrs. Barr and Sons, so that a very enjoyable day was spent.

This firm is far-famed, not only for bulbous subjects, but for practically every type of garden plant, although it is, perhaps, with the Narcissus and Tulip that the name of Barr is chiefly associated, and rightly so, for there can be no better nursery stocks of these subjects in the country than are to be found at Taplow.

Although the Narcissus season was drawing to a close, there were yet many fine sorts to be seen—huge drifts of many varieties—all remarkably clean and healthy, the best display, naturally, being provided by the Poets Narcissi, which were in their prime and occupied an enormous area, forming a huge sheet of orange-lit whiteness.

A large bed of Cassandra, a good garden sort of moderate price, made a grand display, the small, dark red-rimmed cups standing out well against the firm, pure white perianths; another noteworthy sort, as seen growing at Taplow, was Ethelburga, with large, pure white segments and a red-margined, lemon-yellow eye. Oracle, which has a wonderfully symmetrical bloom, and Corinna, also suggested themselves as being good Narcissi for general garden culture, the last-named having a medium-sized, shapely bloom, with white perianth segments and an orange-yellow cup, fringed with deep red. Among really first-class sorts in this collection, one of the grandest was Snow King, which would appear to be an excellent "doer"—it is very beautiful, with large, round perianth segments and a yellow, red-edged cup. Sarchedon, also, was worthy of special note, being of fine form and texture, with rounded, pure white perianth segments and a small, rich yellow cup, fringed with crimson-scarlet.

However, it was not only among the Poeticus Narcissi that grand blooms were to be seen. Nearby, were numerous batches of late-planted sorts, and it was noticeable that these, which were not planted until December—after the late orders had received attention—made a very striking display and had, in a few instances, come through the severe and trying winter better than the early planted bulbs. Noteworthy varieties in this collection were White Pearl, a grand Leedsii, with large, pure white perianth segments and a creamy-white crown; Ixion, a good Incomparabilis of general garden merit; Prince of Wales, a bold Trumpet variety with soft primrose-yellow perianth segments and a bright yellow trumpet; and Prince Fushimi, another Incomparabilis of outstanding merit.

In another portion of this extensive nursery were the general stock beds, together with huge drifts of seedlings, for new Narcissi varieties are being produced continually at Taplow and, as is well-known, Messrs. Barr and Sons have been responsible for the introduction of many striking seedlings, so that a close inspection of the beds of, at present, unselected seedlings, revealed several that will occupy high positions among the élite Narcissi. One exceptionally fine Barrii seedling of grand substance, with a clear cream-coloured perianth and a rich orange cup, caught the eye at once, while among the many Triandrus hybrids also there were some fine varieties.

In the general stock beds the majority of the varieties were over for the season, although there were still good blooms of Proteus, a late giant-flowered Incomparabilis, very fine; Zanzibar, one of the newer Barrii Narcissi of grand form and colouring, and several others.

As stated, it was too early to see many Tulips in bloom; a few early sorts were making a bright display, but had we been a few weeks later, what a glorious picture would have greeted us! Seldom, if ever, have we seen such healthy and vigorous stocks; huge beds of each variety with no gaps or misses in the rows, the Darwins especially giving promise of a brilliant and varied display judging by the large variety grown.

But there were plenty of other subjects in flower to command attention, while the plants out of flower were almost equally as interesting. Messrs. Barr and Sons, in the first place, have an unique collection of bulbous Irises, also of Delphiniums, which, despite the trying conditions, were in fine fettle, and the collection of Paeonies, embracing all the best among garden hybrids, and many rare species, although not yet in flower was sufficient to interest a Paeony enthusiast for some considerable time, especially the species, among which were, to mention but a few, P. corallina, P. Bakeri, P. officinalis in several varieties, including Fire King, P. var. lobata and the rare P. Sabinii; and P. Mlokosewitchii, a rare, dark-foliaged Caucasican species, producing large, single, citron-yellow blooms.

We noted some exceptionally good strains of Polyanthus, the results of years of selection, while it would also appear that Messrs. Barr and Sons have made a speciality of the newer Earlham Montbretias, judging by the huge beds of numerous varieties, notably His Majesty, which were being planted.

It was, of course, too early to see the Bearded Irises, of which the Taplow firm has one of the finest collections in the country, but the dwarf pumila Irises were making a brave display, and formed a very representative collection.

Space would not permit the enumeration of the many interesting herbaceous plants which claimed attention, nor of the numerous alpine plants which are grown for stock purposes; much could be written on the Hellebores alone, some two hundred named varieties being in flower in a specially cool and congenial border, where also were numerous other shade-loving plants.

Lilies also receive special attention from the Taplow firm, and it was extremely educative to see them in their various quarters. L. Martagon, L. testaceum and several others, including a few of the rarer species, were, for instance, flourishing in a specially prepared bed of rather light soil, in a cool, shaded border; in heavier soil, and under more open conditions, were the hardier sorts, such as L. umbellatum, L. Hansonii, etc., all looking very happy; while in yet another part of the nursery, where the soil is naturally moist, were such moisture-loving Lilies as L. giganteum, L. Henryi, L. Parryi, etc., growing in association with Trolliuses and other plants requiring moist conditions.

And then, upon making our way back to the offices and bulb stores—buildings specially constructed for the drying and storing of Narcissus and Tulip bulbs, the two requiring quite different conditions—and after inspecting the propagating houses where, incidentally, was a large batch of fine, healthy pot plants of Romneya trichocalyx, and the frames devoted to plants for bedding, Antirrhinums, Chrysanthemums, etc., we came to the quarters of the lesser bulbous subjects. Here were large drifts of Muscari in variety, Scillas, Anemones and many Tulipa species, notably T. Eichleri, T.

dasystemon and the golden-yellow T. chrysantha; also various Fritillarias, all making a brave display. In this section also there was a grand bed of Iris cristata, some two thousand plants in all, while in a sheltered border against the offices was a comprehensive collection of double-flowered Primroses, providing a bright display of colour.

Much more could be written of the plants seen at Messrs. Barr and Sons' nursery at Taplow; of the Water Lilies, a branch recently extended; and of the various specialised collections of herbaceous plants. The visit was so enjoyable and educative that we look forward to another at, perhaps, some other season of the year, for the variety of plants grown at Taplow is such that there must be a wealth of flowering plants to be appreciated almost throughout the year.

PUBLIC PARKS AND GARBENS.

The Chingford Urban District Council has concluded negotiations for a loan of £1,200 for public walks and pleasure grounds.

The Donaghadee Urban District Council has authorised the surveyor to supply the Ministry of Home Affairs with detailed particulars of the work proposed to be undertaken in the scheme for further development of the commons as a park. Application for a supplemental loan of £1,500 has been made.

The Great Yarmouth Town Council has agreed provisionally to accept the offer of Messrs. Burton and Son to give the Council the disused burial ground, known as Yarmouth General Cemetery, to be maintaind as an open space.

It is proposed that the Parks Committee of the Wallasey Town Council should take over the Upton Park Estate, embracing about 106 acres. Of this estate it is understood that fifty-four acres be reserved for recreation, and thirty for housing.

The Ministry of Health has held an enquiry into an application by the Liverpool Town Council for approval of town-planning scheme No. 2—for Gateacre, Childwall, the Wooltons, and parts of Allerton, Wavertree and Whiston. The scheme embraces ornamental gardens, parks and parkways, riverside walks and the preservation of open spaces.

The Shoreham Urban District Council is making an application to the Ministry of Health for sanction to borrow £500 for the purchase of land for an open space at the Meads, Victoria Road.

The Ministry of Health will hold an enquiry at St. Ives into an application by the Town Council for sanction to borrow £2,250 for laying out rock gardens and constructing a putting green, and for the erection of tea-rooms at Porthminster green and beach.

The Cheadle and Gatley Urban District Council proposes to negotiate for the purchase of about fifteen acres of land at Gatley for a recreation ground.

The City Surveyor and City Engineer of Manchester have been authorised to prepare a report as to the cost of converting the old graveyard of St. John's Church, Deansgate, into a garden.

At a meeting held in Glasgow a few days ago, the question of acquiring a large area in the Cairngorm Mountains as a National Park for Scotland was considered. Sir Ian Colcoquhoun presided and many Scottish societies were represented. It was estimated that a capital sum of about £100,000 would be needed to purchase and equip the area, and Sir John Stirling Maxwell suggested that here was a grand opportunity for some wealthy Scot to provide this amount and thereby render his country a signal service.

SOCIETIES.

GARDENERS' CLUB.

The Annual Meeting and Dinner of the Gardeners' Club was held at St. Ermin's Hotel, Westminster, on the first evening of Chelsea Show (May 22). The accounts showed a substantial balance in hand, and it was resolved to send donations from the Club funds to the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund.

The following officials were elected for the ensuing year:—Chairman, Mr. T. Hay, Hyde Park; Vice-Chairman, Mr. F. Jordan, Ford Manor; Treasurer and Secretary, Mr. F. C. Puddle, Bodnant; Assistant Secretary, Mr. A. Bullock, Copped Hall; Committee: Messrs. C. H. Cook, J. Comber, W. Hales, C. P. Raffill, J. G. Weston, F. G. Preston, G. Taylor and R. Findlay. Mr. T. Hay, on behalf of the members, made a presentation to the Secretary in recognition of his services.

After the meeting, forty-one members sat down to dinner, and a very pleasant evening was spent.

GUILDFORD AND DISTRICT.

The first outing of the season took place on Saturday, May 18. A combination of felicitous circumstances—the perfect weather, the singular beauty of the district, and the extreme cordiality of Sir William and Lady Lawrence—conspired to make the visit to Burford memorable. Sir William and Lady Lawrence personally received the members and conducted them round the gardens, assisted by a daughter and a neice.

The first thing that impresses a visitor to Burford is the situation. Unlike many mansions in Surrey that occupy a position commanding far stretching views, this fine Georgian mansion is built at the foot of Box Hill, where the River Mole cuts through the North Downs—the famous chalk ridge that William Cobbett traced from Farnham to the Shakespeare Cliff at Dover. The little river ripples through these grounds, and from the opposite bank Box Hill rises majestically for some 450 feet. In immensity and grandeur it is almost as imposing as parts of Cheddar Gorge, although different in character. The face of the cliff is well covered with Box and Juniper, sombre in hue, with glints of chalk showing between. Scattered here and there a few Whitebeam make a pleasing contrast, and one solitary Beech was conspicuous in its tender green. This wonderful picture forms the background to the house and garden.

The garden is unlike any visited before. Massed colour schemes, or beds and borders of familiar and popular varieties are not found at Burford. Sir William's leaning, one might, perhaps, state his delight, is along experimental rather than conventional lines. Hence, he has gathered a collection of rare and choice subjects. Many plants have a sentimental value, inasmuch as they were collected by Sir William or Lady Lawrence in Canada, Algiers, Morocco and elsewhere. Diverse in variety and semi-tropical though they are, they live quite happily in gravelly beds and have come through the past winter with very little damage.

One extensive lawn is planted with many rare shrubs, some coming late into flower this year; others gay with blossom. Among them were Pyrus Scheideckeri, P. Zumi var. alba, P. Eleyi, P. Malus var. aldenhamensis, and P. M. var. Niedzwetzkyana.

Trailing over the stump of a dead tree, a Mutisia retusa was in flower; this was brought from the Argentine Andes five years ago. Close by is a collection of Amelanchiers, including A. (florida) oxyodon, A. rotundifolia, A. vulgaris var. cretica and A. alnifolia var. pumila in flower. Further on is a very deep blue Gentian and a Lithospermum—a relation of Heavenly Blue—but with blooms of a rich yellow colour.

In the moraine, a Viola, a gift from Lady Byng, brought from Canada, is highly prized, so also is a small yellow Violet, of Canadian origin. A dusky-faced Pansy—Irish Molly—was noticeable, together with Phlox canadensis, Androsace carnea var. Laggeri, A. Chumbyi Lewisia Finchii, Phacelia sericea, Gentiana acaulis, G. verna, Aethionema Warley Rose, Meconopsis integrifolia var. brevistyla, and M. quintuplinervia, and a small-growing Anchusa with flowers resembling Forget-me-nots. On a wall is a Wistaria brought from China twenty-five years ago, now carrying its white blossoms.

In the houses were, likewise, many unusual plants in addition to Melons, Plums, Peaches, etc., all in a perfectly healthy condition.

Finally, the party was conducted to a beautiful lawn by the mansion, where tea had been prepared out-of-doors. Lady Lawrence presided at the tea table, charmingly decorated with Cowslips picked from the meadows.

Alderman W. T. Patrick expressed thanks for the great kindness extended, and Sir William Lawrence spoke of the pleasure it had given him to receive members of the Assoication, and to learn of the work it was striving to do.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on Friday, May 3, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, A. Keeling and H. Arthur (Secretary).

First Class Certificate.

Phaius Cooksonii var. magnificus.—A large, bold flower.—From J. B. Adamson, Esq.

Awards of Merit.

Odontoglossum Mirum var. Walden and *O. Llewellyn var. Purple Gem.* From J. B. Adamson, Esq.

Odontioda Bradshawiae var. Perfecta and *O. Louise.* From Captain W. Horridge.

Laelio-Cattleya Bunglow (*C. Suzanne Hye × L.-C. Ernestii*).—From Messrs. A. J. Keeling and Sons.

Award of Appreciation.

Odontoglossum Red Admiral var. Brilliant.—From J. B. Adamson, Esq.

Cultural Certificates.

To Mr. J. Howes, for Phaius Cooksoni var. magnificus and Masdevallia Houtteana; and to Mr. A. Burns, for Miltonia Lucia var. Fidelia.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged a group to which a Gold Medal was awarded; Odontoglossums were represented by O. harvengtense, O. Doreen, O. Queen of the Belgians, O. Harold, O. eximium var. regale, and P. Princess Mary; Odontioda Viking, O. Leeana, O. Theresa and O. Olympus var. nigrum were also shown, with Oncidium varicosum var. Rogersii and O. Marshallianum; Lycaste Deppei and L. brevispatha.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, were awarded a Large Silver Medal for a group containing Miltonias and hybrids of the vexillaria section in great variety; Odontoglossum crispum var. Abigail, O. Mercia and O. Philippa; Odontioda Vuylstekeae and Sophronitis grandiflora.

Captain W. Horridge (gr. Mr. A. Coningsby), Bury, staged Odontiodas in variety, Miltonia hybrids and Sophronitis grandiflora. Messrs. A. J. Keeling and Sons showed Odontioda Harlequin, Miltonia Lena, Lycaste Lawrenceana, Bulbophyllum moniliforme and Dendrobium Pierardii.

At the meeting held on Friday, May 17, the members of Committee present were Messrs. J. B. Adamson (in the chair), A. Burns, A. Keeling and H. Arthur (Secretary). Mr. J. Howes was invited to sit with the Committee.

First Class Certificates.

Miltonia vexillaria var. Duke of York.—A large flower, suffused with pink, and with a deep maroon mask. *Miltonia Hyeana var. King William.*—White, petals soft pink, lip lined with pink and with a yellow mask. From Mrs. Bruce and Miss Wrigley.

Miltonia Kennie var. Princess Elizabeth.—A round flower, pink, with velvety-crimson mask. *Odontioda Freda.*—A large flower with pink blotches, and *Trichopilia Hennessii.*—A large, white flower with yellow throat. From Messrs. A. J. Keeling and Sons.

Awards of Merit.

Miltonia vexillaria var. Duchess of York, M. Hyeana var. King Harold, and *M. H. var. King Henry.* From Mrs. Bruce and Miss Wrigley.

Cultural Certificates.

To Mr. A. Burns, for Miltonias, and Dendrobium Victoria Regina; the last-named plant has been exhibited for nineteen years in succession.

Groups.

J. B. Adamson, Esq., Blackpool (gr. Mr. J. Howes), was awarded a Silver-Gilt Medal for a group of Odontoglossums in variety, including O. Everest, O. Amethyst, O. illustrissimum and O. Black Prince; Odontioda Margaret and O. Hippolyta; Cypripedium Enchantress, C. Maudiae, C. Rosettii var. Goliath, C. bellatulum and C. niveum; Vanda cristata and Oncidium varicosum var. Rogersii.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, were awarded a Gold Medal for a group containing Miltonias (in addition to those gaining awards)—M. vexillaria var. Oswaldii, M. v. var. G. D. Owen, M. v. var. Solus, M. v. var. Goliath, M. v. var. virginale and M. v. var. Robusta; M. Hyeana var. King Athelstan, and M. H. var. F. M. Ogilvie. together with Odontoglossums and Odontiodas, Messrs. A. J. Keeling and Sons showed Laelio-Cattleya G. S. Ball and Trichopilia tortilis.

ROYAL HORTICULTURAL.

The following awards have been made to the undermentioned vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Dwarf French Beans.

(Under Glass.)

First Class Certificate.

(46). **Canadian Wonder Improved* (*Flageolet Rouge*), sent by Messrs. W. H. Simpson.

Awards of Merit.

(32). *Bounteous,* sent by Messrs. Watkins and Simpson; (53) **Early Prolific,* sent by Messrs. James Carter and Co.; and (55) **Fifty Days,* also sent by Messrs. James Carter and Co.

Highly Commended.

(34). Perpetual, sent by Messrs. James Carter and Co.; (35) Monster Negro, sent by Messrs. W. H. Simpson; (50) Earliest of All, sent by Messrs. Nutting; (52) Early Warwick (or Early Prolific), sent by Messrs. Harrison; and (56) Helmingham Early Prolific, sent by Mr. C. Orchard.

Commended.

(10). Saxa, sent by Messrs. Zwaan and van der Molen; (15) Ne Plus Ultra, sent by Messrs. Kelway; and (57) Langport Wonder, also sent by Messrs. Kelway.

GENERAL BULB GROWERS' OF HAARLEM.

The Narcissus Committee of the above Society made the following awards at the International Daffodil Show, held at Haarlem, on May 1 and 2.

First Class Certificate.

Narcissus Irene Copeland (*Double*).—White and soft yellow; a double form of an Incomparabilis, with a Paeony-like flower.

Awards of Merit.

(Market Flowers.)

Narcissus Henna (*Incomparabilis*).—Deep lemon-yellow perianth, and a clear orange, tubular cup. Raised by Mrs. R. O. Backhouse.

N. Red Rim (*Poeticus*).—Round, white perianth, and a flat, button-shaped cup, which is greenish-yellow, with a wide orange-red border. Raised by the Rev. G. H. Engleheart.

N. Wide Wing (*Poeticus*).—White perianth, with a flat, yellowish-red bordered cup. Raised by the Rev. G. H. Engleheart.

Awards of Merit.

(Show Flowers.)

N. Commander Byrd (*Bicolor Trumpet*).—Large, lemon-yellow trumpet, strongly frilled; sulphur-white perianth. Raised by Messrs. V. Zonneveld Bros. and Philippe, Sassenheim.

N. Estelle (*Incomparabilis*).—Lemon-yellow perianth, with a deep orange, heavily frilled cup. Raised by Mrs. R. O. Backhouse.

N. Friar (*Leedsii*).—Sulphur-white perianth, and a small, frilled, yellow cup. Raised by Mrs. R. O. Backhouse.

N. J. K. Ramsbottom (*Barrii*).—Clear white perianth, with a deep-yellow, orange-bordered cup. Raised by P. D. Williams, Esq.

N. Marvellous (*Bicolor Trumpet*).—Very large, golden-yellow trumpet, and a firm, sulphur-white perianth. Raised by Messrs. C. Alkemade Azn, at Noordwijk.

N. Mr. Nijgh (*Barrii*).—Clear white perianth; the deep orange cup is frilled and has a yellow centre. Raised by Mrs. R. O. Backhouse.

N. Naomi (*Barrii*).—Flat, sulphur-yellow perianth; the cup has a deep orange border and a butter-yellow centre. Raised by Mrs. R. O. Backhouse.

N. Orange Circlet (*Incomparabilis*).—Perianth lemon-yellow; cup butter-yellow, with an orange-red, distinctly marked border. Raised by Messrs. Barr and Sons.

N. Peerless (*Poetaz*).—Flowers of medium size borne two on each stem; soft apricot-coloured perianth, with a deep orange cup. Raised by Mrs. R. O. Backhouse.

N. Red Knight (*Incomparabilis*).—Perianth creamy-white, with a large, yellow, clear orange-coloured cup. Raised by Mrs. R. O. Backhouse.

N. Twinkle (*Barrii*).—Small, apricot-coloured flower, with a deep orange cup and apricot-coloured stamina. Raised by Mrs. R. O. Backhouse.

N. Vixen (*Incomparabilis*).—Sulphur-white perianth and wide-spreading, clear orange cup. Raised by Mrs. R. O. Backhouse.

ANSWERS TO CORRESPONDENTS.

Border Carnations.—*H. M. M.* We do not know of a book which deals with the commercial growing of border Carnations.

Gardener's Notice.—*T. L.* In the absence of any special agreement as to notice when you were engaged as a head gardener, you are entitled to receive one month's notice determining such engagement.

Growing Cut Flowers Under Glass.—*America.* All things considered, we think the Chichester district would be more suitable than Wokingham for the cultivation of cut flowers under glass. It would have the advantage of sunshine and shelter from the north and would also be in fairly close proximity to a long stretch of southern watering places, as well as fairly handy for the Continent.

Lawn Grass Unhealthy.—*A. E.* Assuming the drainage is in good order, your lawn is, in our opinion, suffering from exhaustion. A liberal quantity of good soil and decomposed organic manure should have been incorporated with the existing soil. It is also important that when a lawn becomes sufficiently established, it should receive careful treatment and attention, otherwise it will soon deteriorate. We suggest fortnightly dressings of a good lawn fertiliser and sulphate of ammonia alternately, at the rate of two ounces per square yard, and 1 lb. per forty square yards respectively, put on in dull weather and well watered in. When the grasses show signs of responding to the treatment, monthly dressings will then suffice. Discontinue the use of fertilisers about the middle of September, and in December give the lawn a good dressing of well-decayed farmyard manure.

Names of Plants.—*G.* 1, Potentilla fruticosa var. Veitchii; 2, Deutzia gracilis; 3, Crucianella stylosa; 4, Alyssum argenteum; 5, Polemonium, probably coeruleum; 6, Helianthemum vulgare var; 7, we cannot undertake to name garden varieties of Roses; 8, Libertia grandiflora; 9, Wistaria floribunda var. alba.—*J. B. D.* Pyrus purpurea.—*A. E. W.* 1, Rhododendron Manglesi; 2, R. Gauntlettii; 3, R. Griffithianum hybrid.—*M. Y. W.* Photinia serrulata, a native of China; has white flowers in April or May, red fruits in autumn. Natural Order Rosaceae.—*C. G.* 1, Rhododendron Maddenii; 2, Saxifraga granulata; 3, Skimmia japonica [Thanks for 1s. for R.G.O.F. Box.—Eds.].

Pond Water Discoloured.—*G. A. H.* The note you referred to appeared in our issue for October 27, 1928 (p. 340). Copper sulphate is the chemical employed for this purpose, half-an-ounce of this being sufficient for 3,125 gallons of water. The quantity to use will, of course, depend upon the size of your pond; to estimate the quantity of water in the pond multiply the length by the breadth, and that by the depth, to find out the number of cubic feet, which should be multiplied by six-and-a-quarter to ascertain the number of gallons of water. Place the copper sulphate in a muslin bag and trail it through the water until it is dissolved.

Rats' Tails on Lawn.—*A. F. K.* The weed is Equisetum arvense (Field Horsetail). It is of common occurrence on deep, loamy soils, especially those that are damp and sour, although we have seen it on dry, sandy soil. If the soil of the lawn is too damp for general garden purposes, it should be drained in the autumn, and the drains need not be more than one foot deep and about the width of the spade. A light dressing of sifted loam, with one-third of newly-slaked lime, could be given after it is mown. This could be repeated in autumn to get more lime in the soil. Sulphate of ammonia would have little effect upon the weed on account of its siliceous, warty coating; but you could give a dressing of half-an-ounce to the square yard, and repeat it two weeks later to encourage the grass to grow. Water the lawn after each dressing, if the weather is dry. Mow the lawn the first time with a scythe or garden shears. The repeated mowing of the lawn will keep the Horsetail very low and impoverish the roots, so that eventually it may disappear altogether.

Tomato and Melon Diseased.—*J. W.* It was quite impossible to diagnose the trouble from the portion of Tomato and Melon plants submitted—it is essential to send the entire infected plant.

Tulips Diseased.—*C. of C.* Your Tulips are attacked with "fire" due to Botrytis tulipae, and also millepedes, Bolydesmus complanatus. A similar trouble was dealt with in the issue of *The Gardeners' Chronicle* for April 13, 1929 (p. 286), which see.

Vine Foliage Unhealthy.—*E. W. P.* The Vine leaves do not show any signs of having been attacked by parasitic fungi. The trouble is a physiological one, the excrescences on the foliage arising from some cause such as the relation between water supply and the requirements of the plant. Attention should be paid to the state of the borders in relation to watering, together with careful attention to ventilation.

Remarks.—Double white Narcissi will probably finish this week, but double white Pyrethrums are coming to hand in good condition, also some double white and mauve Stock from home-growers. All Pyrethrums, both single and double varieties, should become more plentiful now. More outdoor blooms have been on offer during the past week, especially Cornflowers, Delphiniums, Nigella (Love-in-a-mist), Iceland Poppies and Gypsophila elegans. Irises are arriving in large quantities from home-growers and the Channel Islands, but all require immediate sale, more especially the blue and white varieties, the yellow I. Cajanus being in the best condition so far received this season. Carnations and Roses show little change, but best quality blooms find a more ready sale. Lilium longiflorums have become more limited and prices are again on the up grade. Gladioli are receiving more attention; they include The Bride, Blushing Bride, Peach Blossom and Akermanii; a few spikes of the giant-flowered varieties have been offered during the past week. Sweetly-scented Paeonies are arriving from France in good condition, white blooms being most in demand.

Business continues very brisk in the pot plant department, the bedding season being now in full swing, and there is also a good demand for flowering plants for decoration purposes. The most prominent sorts on offer are Hydrangeas in forty-eights and twenty-fours, which vary in price from 2s. to 15s. each; Marguerites, white and yellow; Fuchsias, including some very fine standards; Heliotropes, Ivy-leaved Pelargoniums, Rhodanthe, Rambler Roses, Lilium longiflorum, Mignonette, and a few pink Ericas. Ferns and other foliage plants are somewhat limited in quantity owing to the growers having to deal with large orders for bedding plants.

Remarks.—With a brisk demand ruling for most commodities available in Covent Garden fruit market just now, there is an air of activity in many sections which is helped considerably by the fine weather. Choice fruits, such as Peaches, Nectarines, Melons and hothouse Figs and Grapes, continue to sell well. Australian Apples are in keen demand at slightly higher price levels, while Pears from the same source continue to be popular and move out freely. English Gooseberries have increased in supply, Kent now sending heavy consignments in addition to those from the west of England. Some good Cherries are coming from France and Spain is sending considerable consignments of Apricots. Forced Beans and Peas, as well as best Asparagus, have shown some improvement in demand. New Potatos, however, from all sources, are cheaper. Mushrooms have also realised better prices owing to shorter supplies. Salads continue to do well, and Lettuces in good condition are realising good money. Green vegetables are more plentiful and cheaper, although the few good Cauliflowers available are selling at firm prices. English Tomatos sell well in spite of largely increased supplies, and Cucumbers are maintaining their recently improved price levels.

GLASGOW.

A slight improvement in prices here and there was experienced last week in the cut flower market. Tulips, Roses and Sweet Peas, in particular, suffered from the heat in transit, and the soft and blown condition of the blooms was reflected in the low values ruling. All varieties of Tulips were sold from 1d. to 3d. for 6's; 4d. to 8d. for 12's; and 1s. for specials; while Roses ranged from 1s. to 3s. per dozen; and Sweet Peas, 3d. to 5d. for small bunches; and 9d. to 1s. 3d. for large. Carnations were worth from 2s. to 4s.; Irises, 3d. to 6d. for 6's; special, 8d. to 1s., and 6d. to 1s. 6d. for 12's; Lilac, 4d. to 8d. per bunch; Pyrethrums, special, 10d.; ordinary, 2d. to 3d.; Anemones, 1s. to 2s.; Lily-of-the-Valley, indoor, 1s. 6d. to 2s.; outdoor, 1½d. to 4d.; Paeonies, 1s. per dozen; Lilium longiflorum, 2s. to 3s.; Arums (Richardias), 2s.; Gladiolus The Bride, 6d. to 1s.; Maiden's Blush and Blushing Bride, 1s. to 1s. 3d.; Double White Narcissi, 2½d. to 4d.; N. recurvus, 1s. to 1s. 6d.; and Asparagus, 9d. to 1s. 6d.; and trails, 2s. to 3s.

The fruit market was quiet and steady. Cheddar Strawberries realised 2s. 6d. to 3s. 6d. per lb.; Pineapples, 3s. 6d. to 4s. each; Melons, 4s. to 7s. each; home-grown Grapes, 3s. 3d. per lb.; Gooseberries, 3d. to 4d. per lb.; and Cherries, 16s. (20 lbs.). Australian Pears (Jefferson), sold at 7s. 6d. to 8s. 6d. per box; New Zealand Apples (Jonathan), 15s. to 16s. per case; Grape Fruits, 16s. to 24s.; and Oranges, 25s. to 35s.

There was an active demand for salads. English Lettuces realised 1s. 6d. to 2s. per dozen; Dutch, 2s. 6d. to 3s. 6d.; Scotch, 2s. to 4s.; Radishes, 4s. 6d. per dozen bunches; Syboes, 6d. per bunch; and Cucumbers, 5s. to 7s. 6d. per dozen. Guernsey Peas sold at 1s. 3d. per lb.; Beans, 1s. 6d. to 1s. 8d.; Asparagus, 3s. to 4s. 6d. per bunch; Carrots and Turnips, 1s. to 1s. 2d.; Scotch Tomatos, 1s. to 1s. 2d. per lb.; Guernsey Tomatos, 9½d. to 10d.; and Mushrooms, 2s.

SCHEDULES RECEIVED.

Portsmouth and Southsea Horticultural Society.—Summer Show to be held on Southsea Common, on Wednesday, Thursday and Friday, July 24, 25 and 26, 1929. Secretaries, Mr. F. Baker, N.D.H., and Mr. E. J. Meredith, Alexandra Park, Portsmouth.

Reigate and District Gardeners' Association.—Horticultural Show and Floral Fete, at The Priory, Reigate, on Wednesday, July 10, 1929.—Secretary, Mr. W. A. Dobson, Mabledon, Reigate Hill, Reigate, Surrey.

THE ENGLISH ROCK GARDEN
by
The late REGINALD FARRER

PRICE (two volumes) £3 3s.
Postage extra 1/3

This wonderful book remains, and is likely to remain indefinitely, the classic of the rock garden, for since Farrer no new prophet has arisen in this realm of horticulture. He wrote the book not long before his tragic early death, and there is in it all the flame and ardour of his wonderful genius. To read its pages is to walk with Farrer through the rock garden, and hear his vivid, forceful comments on each of its denizens.

The Iris Society.

YOUNG in years, the Iris Society has already done excellent work on behalf of an increasingly popular garden flower, and its success is largely due to the fact that it counts among its members those whose names have become famous as raisers and cultivators of Irises. Although Mr. J. G. Baker, of Kew, aroused horticultural interest somewhat when, in 1892, he finished his *Handbook of the Iridae,* it was left to Sir Michael Foster to collect species, raise hybrids and cultivate Irises in such a way as to fire the enthusiasm of those who already foresaw the value of the Iris as a garden plant. The Japanese had long since devoted attention to the improvement of Iris laevigata, and given to us the race already known to gardens as Kaempfer Irises, but whereas comparatively few can provide the moist conditions in which these Irises delight, there are thousands who are able to cultivate the broad-leaved, bearded Irises, because many varieties are excellent plants for town gardens. The Iris Society concerns itself chiefly with the tall, bearded Irises, and certainly these are a fine class; there were good garden varieties even so far back as the days of Iris trials at the Royal Horticultural Society's Gardens at Chiswick. Then, however, the groups entitled aphylla, variegata, germanica, squalens, neglecta, and others, were fairly well defined, but now these groups, together with I. pallida and I. Cypriana, and others, have been merged into one another and form the garden section known as tall, bearded Irises. Apart from Sir Michael Foster, probably no individual has contributed more to the success of this group, and incidentally to the success of the Iris Society, than Mr. George Yeld, V.M.H., a veteran raiser whose seedling Irises we admired at York more than thirty years ago. Sir Arthur Hort and Mr. A. J. Bliss are notable raisers and, happily, as in the case of Mr. Yeld, still with us. But alas! the one man who was regarded as the immediate successor of Sir Michael Foster, as an Iris enthusiast, collector, raiser, grower and botanist, is no more; we refer, of course, to the late Mr. W. R. Dykes, whose beautiful book *The Genus Iris* is likely to remain for long the standard work on the subject to which he devoted so much of his time. Mrs. Dykes has joined the ranks of raisers, and her name must be added to those of her late husband, Barr, Perry, Murrell, Wallace, Bunyard and others, who have enriched our gardens with new Irises. It would be unfair, however, to infer from these observations that the improvement of tall bearded Irises has been confined to our own country. M. Denis and M. Mottet, M. Cayeux and M. Millet, in France, and Miss Grace Sturtevant, Mr. Wister and the late Mr. William Mohr in America must be joined with our own raisers in any grateful thanks we accord to workers among Irises. That American gardeners greatly appreciate Irises was made abundantly evident last week when so many members of the Garden Club of America attended the Iris Show at Westminster, the luncheon, and especially the afternoon reception, where they received a warm welcome from Sir William Lawrence, Bt., President of the Iris Society, and Mr. Gerald Loder, President of the Royal Horticultural Society. But the Iris Society is not likely to be satisfied with its present success; it must go from strength to strength, or fade away into an unambitious show organisation. It can do much in its publications, and has already set a very high standard in floricultural Year Books. We feel, however, that notwithstanding the high garden value of tall, bearded Irises, there is abundant room for exploration and imagination in regard to other sections of the genus Iris and we trust the society will encourage experiment in these directions. An Iris Society, to fulfill its title, must take under its wing the popular and the rare bulbous Irises, Irises for the alpine garden and the woodland, Irises for the unheated greenhouse and for the water garden. There are possibilities and difficulties, of course, but what is possible is often difficult at first, and difficulties overcome often extend the range of what is possible, therefore we hope the Iris Society will encourage the discovery and cultivation of species and natural varieties, the raising of hybrids and garden forms, and experiments in regard to the control and prevention of the few pests and diseases to which Irises are more or less liable..

Bearded Irises in St. James's Park.—The value of the bearded Iris as a flowering subject for town gardens is emphasised by the bright display of innumerable varieties on the margins of the lake in St. James's Park, and which are now at their best. Among the varieties which contribute chiefly to this very charming effect are Gagus, Madame Blanche Pion, Mrs. H. Darwin, Princess Victoria Louise, flavescens, Ballerine, Hamilcar, Innocenza, Tamar, Afghan Prince, Fro, very fine; Alcazar, Lent. A. Williamson, Prospero, Titan, Queen Caterina, pallida var. Como, Madame de Stael, Prosper Laugier and pallida var. odoratissima. On the small, round island at the Palace end of the lake Iris sibirica and Iris orientalis var. Snow Queen are flowering gaily, while further colouring is provided by bright beds of Violas, Rehmannia angulata, moisture-loving Primulas, and various richly-coloured Mimulus hybrids, brightest among which is the dwarf Mimulus Whitecroft's Scarlet.

Mr. C. Savidge.—Mr. C. Savidge has been appointed Assistant Horticultural Lecturer at the Cheshire School of Agriculture. He was previously for two years Assistant Horticultural Lecturer to the Norfolk County Council, and carried out trials against capsid bugs, etc. Before this he had been for six years on the fruit and market garden belonging to Mr. Newborn, of Wisbech, and has had experience with Colonel Clayton of the same district. Mr. Savidge was trained at the Kirton Farm Institute, Lincolnshire, and at Reading University. He holds the Royal Horticultural Society's General and Teachers' Certificates.

"Hardy and Half-hardy Plants."—Part II of this new publication is as interesting as the initial effort, and contains a coloured plate of Kneiffia (Oenothera) fruticosa var. Youngii. The other plants illustrated are Cynoxylon floridum, better known as Benthamia fragifera; Corysanthes macrantha, the New Zealand Nauticus Orchid, not in cultivation in this country; Calceolaria Fothergillii, a distinct Slipper-wort from the Falkland Islands; Meconopsis heterophylla, Lathyrus pubescens, Citrus trifoliata, Sarracenia purpurea, Morisia hypogaea, Philesia buxifolia, Castilleja liniariaefolia, Primula Paulinae, Arisaema triphyllum, Glaucium flavum, Epigaea repens, Gladiolus edulis, Iris Delavayi, Chamaescilla corymbosa, Tecophilaea cyaneocrocea, Berberis Wallichiana and Asplenium Petrarchae.

Allotment Holders and Unemployed Pay.—Thousands of allotment holders in South Wales and other places who were unemployed, have been in constant fear of losing their unemployment allowance by working on their allotments during the day time. In certain districts the men were warned that they were likely to forfeit unemployment pay if they continued to work their plots instead of devoting the day to looking for employment. The National Union of Allotment Holders took the matter up with the Ministry of Labour, and obtained an assurance that, provided a man loses no opportunity of seeking employment, his work on the allotment will not jeopardise his claim to unemployment pay.

Leeds Flower Show.—The annual Leeds Flower Show, organised by the Roundhay (Leeds) Horticultural Society, will be held this year on Tuesday and Wednesday, July 16 and 17. A few years ago, this show was nothing more nor less than a friendly competition between gardening neighbours; now, it is one of the finest shows in the north of England, and the site—the beautiful Roundhay Park—is admittedly one of the finest natural show grounds to be found. The Secretary is Mr. W. F. Kitchingman, 8, York Place, Leeds.

Our American Namesake—Although we have no real connection with our American namesake, *The Gardeners' Chronicle of America,* we take a fraternal interest in this excellent journal, which claims to be the only "all-gardening" magazine in America. It is a monthly, not a weekly publication, and is priced at 25 cents. The May issue is of particular interest to English readers, as it contains an article by John Birkentall, entitled, "The Famous Kew Gardens," in which the writer states—no doubt with truth—that every year thousands of American visitors to these shores go to Kew as part of their exploration of London and its vicinity.

A New Open Space for Manchester.—On June 5, the Manchester City Council approved a scheme for the purchase, from Lord Egerton, at the nominal price of £450 per acre, of an area comprising one hundred acres, at Alexandra Park, on the south side of the city, formerly used as an aerodrome. The site is to be converted into a "public park, open space, recreation ground or exhibition or show ground." Not less than twenty acres is to be fenced off as a recreation ground, not to be encroached upon except for use in connection with any show or exhibition on the remainder of the land, and Lord Egerton stipulates that no portion of the land is to be used for aviation, motor or motor-cycle races, or for mechanically propelled swings or roundabouts. Not more than eleven acres are to be covered at any time with buildings, and these shall only be for shows and exhibitions.

Experiments at the Kirton Agricultural Institute.—The Kirton Agricultural Institute has just issued a most interesting Report and Summary of results of experiments carried out during 1927. The experimental work undertaken in connection with the production of Potatos and Sugar Beet has been extensive, and the contents of the *Report* disclose vital facts discovered in the cultivation of both. The results of different manuring of early and maincrop Potatos, and the trials of Scotch "seed," mature versus immature, and of Dutch "seed," should be of great interest to all agriculturists. Valuable information is also given on the cultivation of Wheat, spring Cabbage, Peas, Broccoli, etc. Another section of the *Report* deals with plant pathology, pests, and the weather during 1927. Primarily, the results of the experiments are published for the information of residents in the Holland division of Lincolnshire, to whom they are issued free, but to those outside the division the *Report* is obtainable at a cost of 1s. 1d. post free, on application to The Principal, The Agricultural Institute, Kirton, near Boston, Lincolnshire.

American Gardens at Saltwood.—By the kindness of Mr. Alfred C. Leney, the American Gardens at Saltwood, near Hythe, Kent, are opened to the public on a few Wednesday afternoons during June. During Whitsuntide, when they were also thrown open, many visitors enjoyed the beauty of the Rhododendrons, Azaleas, Magnolias, flowering Cherries, Camellias, Pyruses and other early-flowering trees and shrubs, while Tulips were glorious in a dell where Narcissi still lingered and Forget-me-nots made sheets of blue. These gardens were made many years ago on a barren, peaty site, by the late Archdeacon Croft, Rector of Saltwood, with the skilled assistance of the late Mr. W. Acomb, who had an early training in Messrs. Backhouses' Nurseries at York.

Beautifying South Wales Mining Dumps.—The conversion of heaps of mine refuse into gardens is work that will have the blessing of all and the help of many who love flowers and gardens. The process of conversion is being carried on in South Wales and especially in Monmouthshire, where the Pilgrims' Garden Association is making waste places beautiful by planting and tending shrubs and flowers and making desolate areas places for rest and recreation.

American Lady Horticulturists at Kew.—The party of lady members of the Garden Club of America now on a visit to Britain, spent the afternoon of Monday, June 3, at Kew. To the number of nearly one hundred they were welcomed at the main entrance to the gardens facing Kew Green, by the Director, Dr. Hill, and several members of the garden staff. During an extended tour of the pleasure grounds and greenhouses, the visitors were particularly impressed with the Azalea Garden and Rhododendron Dell—which were seen at their best, the Rock Garden, glorious masses of the white form of Wistaria multijuga, and the wonderful Tree Ferns and other occupants of the Temperate House.

Naphthalene as a Remedy for Red Spider.—A writer in a German contemporary recommends the use of naphthalene powder as a remedy for red spider in hothouses, as being simpler in application and cheaper than hydrocyanic acid gas, and also less likely to injure the inmates of the house. The quantity used is five kilogrammes to every one hundred square yards of ground area; it is strewed on the ground, and the house—the atmosphere in which should be damp—closed for thirty-six hours. The evening is the best time for the operation (which should be performed preferably in dull weather), as it may then be closed for two nights and only one day. All the red spider will be found to be dead when the house is opened, but it is advisable to repeat the operation a fortnight later, so as to kill all insects which have hatched out since the first batch. On fruits, the naphthalene is stated to have no effect at all; and the slight smell which is noticed afterwards on Cucumbers can be got rid of by laying the Cucumbers for a few hours in some fresh grass.

Legacy to Gardener.—The late Mr. James Charles Ellard D'Esterre, of Elmfield, Millbrook Road, Southampton, who died on January 5, left £75 to his gardener, Mr. Bertram J. Morley.

Mr. W. E. Stewart.—About a month ago, Mr. W. E. Stewart entered upon his new duties as horticultural assistant to Mr. W. W. Pettigrew, V.M.H., Superintendent of the Manchester Public Parks. It must be obvious that such a young man must have made excellent use of his opportunities, otherwise he could not have secured his present position in view of the keen competition for it. Mr. W. E. Stewart is the son of Mr. W. Stewart, N.D.H., Superintendent of the Royal Hospital Gardens, Chelsea, and under whom he received his early training. He studied botany at the Chelsea Polytechnic and took the surveying course at the Regent Street Polytechnic. He obtained experience in landscape gardening while with Mr. G. G. Whitelegg, Chislehurst; then followed a further period of training at the Royal Gardens, Kew, after which Mr. Stewart extended his experience in the garden-crafts department of Messrs. Bakers, Wolverhampton. He then became an assistant in the Royal Parks, London, under Mr. T. Hay, M.V.O., V.M.H., and so to Manchester.

MR. W. E. STEWART.

The Control of Potato Sickness.—During recent years severe losses have been incurred by Potato growers in Lincolnshire, Yorkshire, Lancashire and other counties as a result of a complaint known variously as "Potato Sickness," "Potato Eelworm," and "Potato Dab," so that growers in general will welcome the results of Mr. E. E. Edwards' investigation of this trouble and of methods for its control, which appear in the June issue of the *Journal* of the Ministry of Agriculture (Vol. XXXVI, No. 3). It was previously thought that the trouble was due to unsatisfactory conditions of soil fertility, but the results of the experiments designed to ascertain the real cause, point very much to the eelworm, Heterodera schachtii, and the fungus, Corticium Solani, as being the real culprits, as non-sterilised soil, known to contain these two organisms, and sterilised soil innoculated with them, gave rise to infected plants, while plants grown in clean, sterilised soil were perfectly healthy. In the matter of control, applications of various chemicals to the soil were tried, those giving the most promising results being drained creosote salts (a name applied to a crude naphthalene containing small percentages of other coal tar products), carbon disulphide, calcium cyanide and calcium cyanamide. Tables showing the crop returns from the various treatments, together with the cost per acre, are given, and it would appear that the drained creosote salts are likely to prove of most economical value in the control of this serious Potato trouble. Mr. Edwards concludes by stating that these salts are worthy of further trial (the cost of the dressing was £4 per acre), and suggests: "This chemical should be broadcast twelve days before the Potatos are planted, at the rate of about 8 cwts. to the acre, and then immediately ploughed in to a depth of six inches."

American Gooseberry Mildew in Scotland.—The Department of Agriculture for Scotland, in accordance with the provisions of the American Gooseberry Mildew (Scotland) Order of 1920, intimates that occupiers of nurseries on which Gooseberry bushes are grown for sale, or with a view to the sale of the fruits to factories, are required to give immediate notification to the Department or local authority of any outbreak or suspected outbreak of American Gooseberry mildew on their premises. They are also prohibited from selling or removing any bushes or fruits affected by the disease, except under the authority of a licence granted by the Department. The Department is authorised by the Order to deal with any grower who fails to take steps to combat the disease.

Bitter-pit of Australian Apples.—An account of the co-operative work carried out by the Department of Agriculture of Western Australia, and the Council for Scientific and Industrial Research, on Bitter-pit of Apples in Australia, with special reference to the variety Cleopatra, has been compiled by Messrs. W. M. Carne, F.L.S., H. A. Pittman, B.Sc.Agr., and H. G. Elliot, and issued as *Bulletin* No. 41 by the Council for Scientific and Industrial Research of the Commonwealth of Australia. To summarise this work, which is well illustrated, it is stated there are two distinct bitter-pit diseases of pome fruits in Australia (1) the true bitter-pit, which originates almost solely in fruits in store, and (2) "cork," a disease which originates on the fruits while still on the trees, and never in store. "It is the former disease which constitutes the most serious defect of Australian Apples in European Markets." The non-parasitic spot diseases are clearly defined in the work, and classified as Jonathan spot, cork, and true bitter-pit, while cork, originally defined by Mix, has been re-defined and has been extended to include (a) internal cork, (b) crinkle cork, (c) blotchy cork, which is the chief form of the bitter-pit occurring on Apples while still on the trees, in Australia, and (d) drought-spot cork, all of which are discussed and fully described. The true bitter-pit, or storage bitter-pit, has been identified in two forms:—(a) mild pit, with small, rather inconspicuous surface lesions, occurring in both cold and ordinary storage, and (b) severe pit, characterised by relatively large pits, dark in colour, and occurring only in cold-stored fruits. Storage pit is shown to occur in fruits of susceptible varieties when picked while immature. ‘Picking maturity" and "full maturity" are discussed and defined, together with various methods of testing maturity, starch testing for picking maturity, and the "pressure tester" being dealt with at length. It is finally stated, in this comprehensive work, that Apples for export, if loss by bitter-pit is to be reduced to a minimum. should not be picked until they have reached the stage defined as "picking maturity," and, having been gathered, they should be placed in cold storage so soon as possible: exposure to warm temperatures increases the liability to internal breakdown, as also does gathering the Apples after they have passed the "picking maturity" stage. A very valuable contribution to the somewhat limited data concerning bitter-pit of Apples.

Association of Economic Biologists.—The Annual Field Meeting will be held at Cambridge, on Friday, June 21, and the following programme has been arranged:—The party will meet at the railway station, Cambridge, at 11.38 a.m. (Liverpool Street, 10.5). They will then proceed by No. 2 'bus starting from Market Street to the University Farm, where, by the courtesy of Sir Rowland Biffen, they will inspect the experimental plots and greenhouses. Members should provide themselves with sandwiches. After tea (1s. 6d. per head) the party will return by 'bus to Cambridge, where, by the courtesy of Sir William Hardy, they will visit the Low Temperature Research Station. An informal dinner for members, both ladies and gentlemen, will be held in Christ's College, on Friday evening, at 7.30 p.m. Members may bring guests. Arrangements have been made whereby not more than thirty of the party may be accommodated in Christ's College for the night. The charge for dinner, accommodation, attendance and breakfast will be 15s. 6d. per head. Lady members may obtain accommodation at the following hotels: The University Arms, the Blue Boar, the Lion, or the Belle Vue. On Saturday, by the courtesy of Professor Stanley Gardiner, a party will leave Cambridge at 11 a.m. and visit Wicken Fen, returning at about 4.30 p.m. Lunch and tea will be provided by Professor Gardiner. Members who wish to attend the above meeting are requested to notify the General Secretary, Dr. J. W. Munro, Imperial College of Science, London, S.W.7, before June 17, of their intention to do so, and to specify whether they wish:—(1) to attend the dinner, and if they propose to bring guests; (2) to sleep in College on the night of June 21; and (3) to attend the excursion to Wicken Fen.

Down House, the Home of Charles Darwin.—On June 7, Down House, at Down, Kent, the home of Charles Darwin from 1842 to 1882, and now held in custody for the nation by the British Association, was formally declared open to the public, many distinguished persons being present at the ceremony, including members of the General Committee of the British Association, representatives of Darwin's family and of Societies with which he was associated, and other distinguished guests, the chair being occupied during the short ceremony by Sir William Bragg, Chairman of the British Association, Sir Arthur Keith being the chief spokesman. The acquisition of Down House by the Association is the direct outcome of an appeal by Sir Arthur Keith, who, in concluding his presidential address on the present position of Darwinism, at the meeting of the British Association at Leeds in 1927, made a strong plea for the preservation of Down House as a memorial to Darwin, and the appeal had scarcely been made before a telegram was received from Mr. George Buckston Brown, F.R.C.S., stating that he would buy the property. Mr. Brown acquired Down House from Professor Charles Galton Darwin, grandson of the famous naturalist, and gave it to the Association with a generous endowment for its maintenance and preservation, at the same time expressing a wish that the property be regarded as a gift to the nation, and that the public be admitted without charge. Down House has now been restored so nearly as possible to the condition it was in when occupied by Darwin, who spent the last forty years of his life there. In America, a Committee has been appointed to co-operate with the British Association's Committee in an endeavour to recover so much Darwiniana as possible, and already many Darwin relics have been brought together at Down House, which will stand as a lasting memorial to Charles Darwin, the greatest of all naturalists.

Window and Front Garden Competition in Dublin.—It may be taken as a sign of good horticultural times for Dublin that the Independent Newspapers, Ltd. (proprietors of the *Irish Independent*, *Evening Herald*, etc.) have seen fit to inaugurate for that city a Front Garden and Window-box Competition in which the successful town and suburban amateur gardeners will receive at least £100 in cash prizes. The Dublin Garden and Window-box Guild is probably responsible for this generous stimulus, for this almost nebulous body, without money and with the patronage only of the far-seeing few, has for the past two years carried out a most successful competition which, although confined to some 8,000 occupants of dwellings erected under municipal housing schemes, attracted considerable attention. The competition is divided into four classes, two for front gardens and two for window-boxes, and all governed by the valuation of the house or flat; the prizes are £10, £5 and £2 10s., respectively, with ten consolation prizes of £1 in each class. The Irish Independent Newspapers, Ltd., are to be congratulated on their enterprise in making this big effort to cater for the rising popularity of gardening among the masses, whose individual requirements may be negligible, but whose collective order would certainly be appreciated by many houses in the trade.

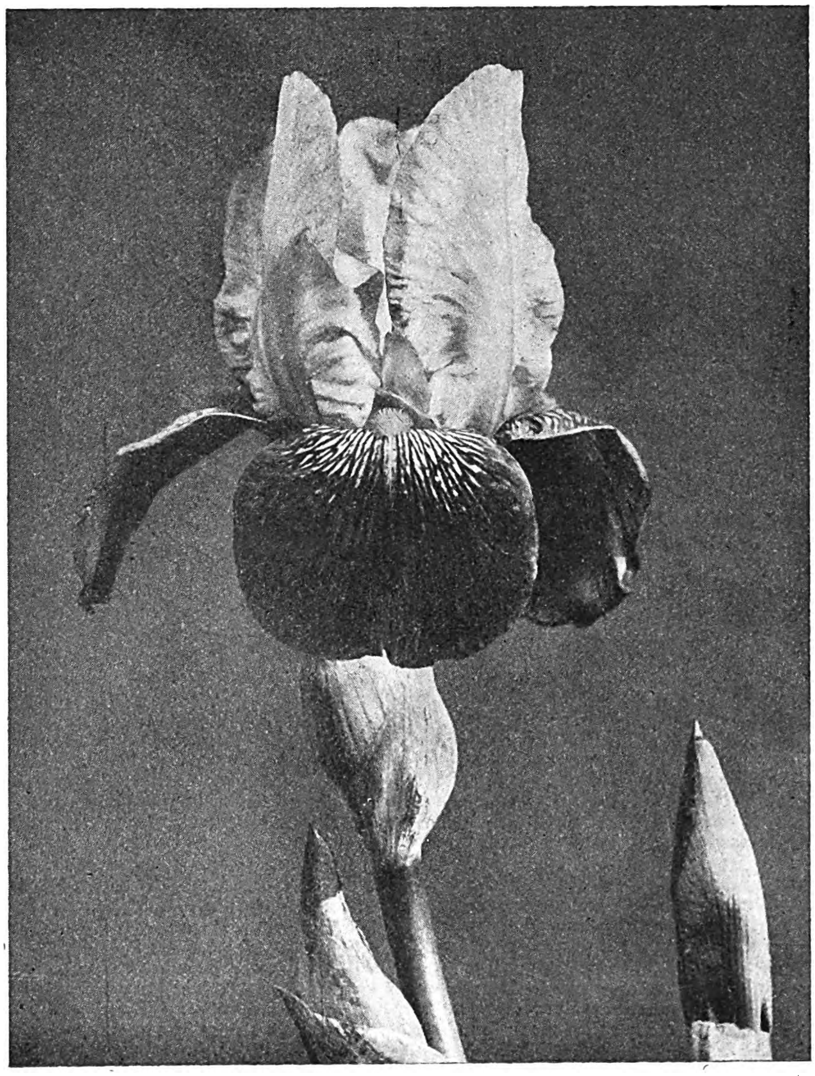

FIG. 219.—IRIS JOAN CURTIS.
Silver Medal, Iris Society, June 6. Shown by Mr. Amos Perry.
(see p. 450).

Appointments for the Ensuing Week.—TUESDAY, JUNE 18; York Gala (three days); WEDNESDAY, JUNE 19: Cheltenham Spa Floral Fête (two days); Royal Norfolk Agricultural Society's Show (two days). THURSDAY, JUNE 20: Newcastle and District Horticultural Society's meeting. SATURDAY, JUNE 22: Leeds Paxton Society's Hydrangea Show.

"Gardeners' Chronicle" Seventy-five Years Ago. — *Kilmarnock Weeping Willow.* — This beautiful weeping plant having lately attracted attention, its history may not be uninteresting. There lived, in a sequestered corner of Monkwood estate, near Ayr, an aged botanist, named James Smith, an enthusiastic lover of plants, and a zealous collector. From him, Mr. Lang, nurseryman, Kilmarnock, purchased one plant, about ten years ago. Afterwards Mr. Lang procured a few more plants from Mr. Smith; and as the old gentleman died shortly after, he never had an opportunity of ascertaining where he procured the variety. It is probable, however, that he found it growing wild, as the species, Salix caprea or Palm Willow, is one of the most common plants in the country. Mr. Lang has since been engaged in propagating the plant, and nearly one thousand have been sold. Sir W. J. Hooker received two plants of it in spring, 1852, and having observed, during last summer, how exceedingly ornamental it was, he gave Mr. Lang a decided opinion, stating that he thought very highly of it, and that it was much admired in the Royal Gardens at Kew. The tree flowers freely in the month of April, has broad, glossy leaves, every branch is curved gracefully downward, and it is as hardy as the most hardy plant we have, being in fact, a native of the country, and not, like the Salix babylonica, introduced from a foreign clime. The name of Kilmarnock Weeping Willow was bestowed upon it to distinguish it from the common Weeping Willow, the Napoleon Weeping Willow, and the American Weeping Willow; it is quite distinct from either of these varieties, having leaves two inches broad. *Gard. Chron., June* 17, 1854.

Publication Received.—*Handbook of the Parks and Recreation Grounds of the City of Manchester*, by W. W. Pettigrew, V.M.H.; pp. 142, illustrated. The Manchester Parks Committee, Town Hall, Manchester, price 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Atmospheric Conditions for Orchids.—The spell of bright, sunny weather, with the prevailing dry, easterly winds, experienced during the latter part of May, made it difficult to maintain a genial atmosphere in the cool houses. To overcome these difficulties successfully calls for close attention to details. Additional shade is needed during the hottest part of the day by the use of an extra blind or a thin coat of suitable shading put on the glass and the blinds used in conjunction with it. Hall's distemper may be diluted with water and applied cold; this water paint is very easily removed later on when not required. Ample ventilation is desirable, both day and night, at this season, but when drying winds are prevalent, discretion is needed when using the ventilators, or the atmosphere in the houses will quickly become dry, in spite of frequent damping down. On the other hand, when the outside conditions are moist and genial, the ventilators may be opened both top and bottom to their full extent. In the cool divisions, fire heat should not now be necessary for several weeks to come, unless there is a spell of cold, wet weather, when a slight warming of the pipes will be beneficial. Thrips, etc., should be kept in check by spraying the foliage with a weak solution of an approved insecticide every fortnight. In low-lying, moist districts, during damp weather, it is not advisable to damp down heavily or very late in the day, especially when the ventilators are in full use, and there is no fire heat.

The Warmer Houses.—The extra sun heat should prove beneficial to most of the occupants of the warmer divisions, provided careful attention is given to shading and ventilation. Atmospheric moisture may be maintained by damping the paths and lower stages as occasion demands, while occasional syringing between the pots and light spraying overhead is beneficial during hot weather. Sufficient ventilation should be given to allow a free circulation of air and to keep the atmosphere buoyant. If the ventilators are closed in the afternoons to secure the necessary rise in temperature, they should be opened again slightly in the evening to keep the atmosphere sweet. In most districts a little fire heat is necessary at night for the warmest divisions; this, with a little air admitted, keeps the atmosphere buoyant. As the growths advance, more water will be needed at the roots each time the compost approaches dryness; saturation for long periods should be avoided. As the growths are nearing completion more light and air should be given to assist in their full development. At this stage the plants should not suffer from lack of water, the quantity being reduced as the growths become complete. Very little water is required to keep them in a normal condition, especially if the flowers are not being produced until a later date. Those kinds which flower on completion of the growth should be given sufficient water to support the plant over the flowering period.

Tall-growing Dendrobiums.—Strong-growing kinds, such as D. Dalhousieanum, D. moschatum, etc., are now commencing to grow, and any necessary repotting may be done, using well-drained pots and a fairly coarse compost of A.1. and Osmunda fibre, used in a rough state, with a little Sphagnum-moss, adding charcoal to keep it open. This should be pressed firmly about the fleshy roots, care being taken to avoid injuring them during the operation. Careful watering is necessary until the roots are well advanced, when copious supplies will be needed each time the compost appears dry. The plants thrive well in the humid and buoyant atmosphere of the warm house. Similar conditions may be afforded to the evergreen section, embracing D. densiflorum and its varieties, D. Brymerianum and D. suavissimum. These Dendrobiums will require more shade during their growing season than the sun-loving D. Phalaenopsis and D. formosum.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

March Moth Caterpillar.—Since writing my last notes, I have been thinning the fruits on our bush and cordon Apple trees, and have been astonished at the number of fruitlets damaged by this pest. Not content with devouring the foliage, it will, on occasions, attack the young fruits. Where the fruits are short-stemmed and clustered together, the necessary shelter is afforded for this caterpillar to carry on its destructive work, and every Apple in the truss may be damaged. In some cases the damage is only very slight, but in others the injury may be quite a quarter-of-an-inch deep. These damaged Apples do not fall from the trees as is the case when attacked by the larvae of the codlin moth and the Apple sawfly, hence the importance of thinning. If this is carried out immediately, and a sharp watch is kept for signs of all three pests, much of the trees' vitality will be saved by the early removal of all the damaged fruits. I have found that a pair of Grape scissors is the most useful and handiest implement to use for the purpose of thinning Apples and Pears.

Layering Strawberries.—For very early forcing and, indeed, for any purpose, an early start is essential to secure strong, healthy plants. The best runners are obtained from plantations made the previous year and which have not been allowed to flower. They should be layered into small pots—2½ inch, or small sixty-size pots. The requisite number of pots, with some fairly rich, sifted soil, should be taken to the layering ground and filled as required with the prepared compost. The plantlets should be thinned down to four or five of the best per plant, the pots plunged to their rims in the soil, in alternate rows, in groups of a dozen or so, to facilitate watering, and a plantlet secured in each pot by means of a peg. Moisture is essential to induce rooting, which, if the conditions are favourable, will only take from three weeks to a month. For the general planting the most economical method is to stir the soil between the rows, water it if necessary, and layer the plantlets in groups. Keep them in contact with the soil by placing a flat stone on each stolon. Frequent waterings are necessary during dry weather, and especially so when they are being lifted for transplanting to fruiting quarters, an item only too frequently overlooked, with the result that the roots are often badly broken and bruised. Early fruits may be obtained next season by planting on a south border, from which Potatos have been cleared, and keeping them well supplied with moisture in the early stages of growth.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Climbers.—These are now making rapid growth on walls and trellises, and the young growths should be tied in carefully, otherwise they will become a twisted and tangled mass which it will be found impossible to part without destroying the best of the wood required for next year's flowering. In the milder districts of the country and around the coast we often see some of the rarer climbers that usually need the protection of a greenhouse, growing against walls. Hard winters such as we have recently experienced, settle the fate of many of these tender plants. None the less, they are of fairly rapid growth and well worth planting again. Those who have visited gardens where these plants are well-grown have happy memories of pictures it is well worthy trying to repeat. Clianthus puniceus (the New Zealand Glory Pea) is one of the most handsome climbers one could wish to see. Solanum jasminoides, with its delicate white, starry flowers, is a rapid grower in warm, light soils, while S. crispum is hardy enough for the open in favoured districts but is worthy of a place on a wall. Berberidopsis corallina, with its large, spiny leaves and coral-red trusses of flowers continues to flower for quite a long period. Passiflora coerulea deserves to be planted more frequently; likewise the white variety known as Constance Elliott. Both are fairly hardy, but a southern or western aspect is best. Lapagerias should be planted at the base of a cool wall, in sandy peat and leaf-soil; this is often ruined through neglect in watching for slugs which seem to have a special liking for the tender young growths that spring from the base. Lardizabala biternata is a good evergreen for covering walls, reaching between twenty and thirty feet in height. These are a few subjects that might with advantage be tried where moderately mild conditions prevail, but there is no limit to the selection for the mild, humid districts of the south and south-west. All can be procured in pots and planted now, so that they will become well-established before winter.

Hardy Annuals.—Take advantage of moist conditions to thin out annuals to their final distance apart. This is a much neglected part of garden operations and for that reason we seldom see the true beauty of these beautiful flowers. Each plant should have sufficient room for development, according to the kind grown. Stakes, which should preferably be of small, twiggy Hazel branches, should be placed among and around them at an early date, so that the growths can grow through them and find the necessary support without tying.

Perennials.—It is not too late to sow seeds of many perennials and biennials for flowering next season, and this ought to be done wherever there is room for raising a stock. Delphiniums, Lupins, Aquilegias and Campanulas are a few of the commoner kinds that are useful for cutting, and they may be raised at little cost. When sowing, use the best strains only; a good plant needs no more attention than a poor one.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Pot Strawberries.—The forcing of Strawberries is drawing to a close, and extra fine crops have not been very conspicuous this season. Many plants have been blind, others have produced both small and weak flowers, especially among plants which were layered rather late. Years ago no one experienced much difficulty in obtaining an abundant supply of runners, but Strawberries have deteriorated, and it is wise to obtain an occasional change of stock from a distant part of the country, or buy a few fresh runners yearly. Runners so obtained need not be potted up for forcing, but a few rows put out will give strong plants for runner production the following year. If young plants planted last August and intended to give the annual supply of runners for forcing and planting, have been divested of all their flower spikes, the recent rains will have encouraged an abundance of premier runners. These should be dealt with before they root into the bed; clean pots and good compost should be prepared without delay, and whether three-inch or larger pots are used matters little, provided they are clean and dry, and the compost dry enough to withstand firm ramming. Heavy, calcareous loam is sufficiently rich to grow good plants without the aid of manure; old lime rubble, ground oyster shell and bone meal may be used not only as correctives, but as necessary ingredients, and the longer the compost lies in bulk before use, the better it will be. Watering is always a difficult and laborious operation, but one upon which the success or otherwise of the crop depends, and must never be performed in a careless manner. The judicious use of liquid manure while the plants are growing is of great benefit and assists in the formation of stout and well-developed crowns.

Cucumbers.—As plants in frames will now be in full bearing, where manure is plentiful and frames or pits are well managed, a large summer supply from this time forward should be forthcoming. No time should be lost in clearing out old plants from houses, provided they can be spared. Young plants make rapid progress, and replanting wherever practicable is most profitable and also the most pleasing after the houses have been thoroughly cleansed. If required, frames in which Potatos and other forced vegetables have been grown should be cleansed and planted as they become vacant. After this date, plants grow freely; they should be planted thinly and the young growths frequently stopped to prevent crowding. When in free growth, early morning ventilation should be given, closing the frames again early in the afternoon, and syringing at any temperature ranging from 80° to 100°. If the summer proves extra fine and warm, the plants will require water at least twice a week—not cold, and in driblets, but in liberal supplies given through a fine-rosed can at a temperature of 80° to 90°.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Calceolarias.—The herbaceous Calceolarias are delightful as pot plants when well-grown, and, provided a reliable strain is obtained, flowers in a variety of shades may be secured. Seeds may now be sown in a moderately cool house, as Calceolarias are comparatively hardy and resent too much heat at all stages of growth. Owing to the seeds being so minute, the soil surface should be fine and even and, after sowing, just a fine sprinkling of sandy soil will be sufficient to cover the seeds. Shade the receptacles from bright sunshine and stand them in a cool house, keeping the surroundings moist. When germination is effected, care should be taken to prevent the soil becoming too dry, otherwise the seedlings will be scorched by the sun. The seedlings should be pricked off so soon as they can be handled, in a mixture of loam, leaf-mould and sand, and grown on under the coolest conditions possible. Continue to protect them from strong sunshine, and repot them when necessary; never allow the plants to become starved. Watch carefully at all times for green fly, as this pest will soon ruin the plants if allowed to remain unchecked.

Malmaison Carnations.—As these plants pass out of flower they may be stood in cold frames and allowed plenty of fresh air. This treatment will prepare the young shoots for layering, which may be done at intervals, so that the potting and flowering may be extended over a long season. The best of the one-year-old plants should be selected for growing on next year, and may be potted on into larger receptacles when convenient.

Chrysanthemums.—Where cuttings of Chrysanthemums were inserted as advised, to be grown on single stems in six-inch pots, the plants should now be ready for placing into four-and-a-half inch receptacles, and, in about three weeks' time they may be moved into their flowering pots. Retain the first bud that appears. After potting, the plants may be sprayed frequently in hot weather, and, so soon as the receptacles are filled with roots, apply weak liquid-manure and soot water.

Francoa ramosa.—Established plants of the Bridal Wreath, as this is called, which have been grown under cool conditions, will now be producing flower spikes, and until the flowers are opening, may be fed liberally with liquid manure. F. ramosa is by no means a tender subject, and may be placed out-of-doors if desired to retard its flowering; by introducing batches into a warm greenhouse at intervals, it may be had in flower over a long period. Seeds may be sown now to secure good plants for next season; selected forms may be increased by means of side-growths.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Chicory.—A sowing of Chicory may now be made, allowing fifteen to eighteen inches between the lines. When the seedlings are large enough to handle, thin them to a fair distance apart so as to secure good crowns for forcing during the winter.

Endive.—Seeds of the Moss-curled Endive may be sown, to be followed in about two weeks' time by a sowing of the broad-leaved Batavian Endive, which withstands the winter better than the Moss-curled type, which is useful for consumption during the autumn, but is very easily damaged by frost and dampness.

Onions.—If supplies of young Onions are required for salads, a further sowing should be made in rows ten to twelve inches apart, which allows ample room for this crop.

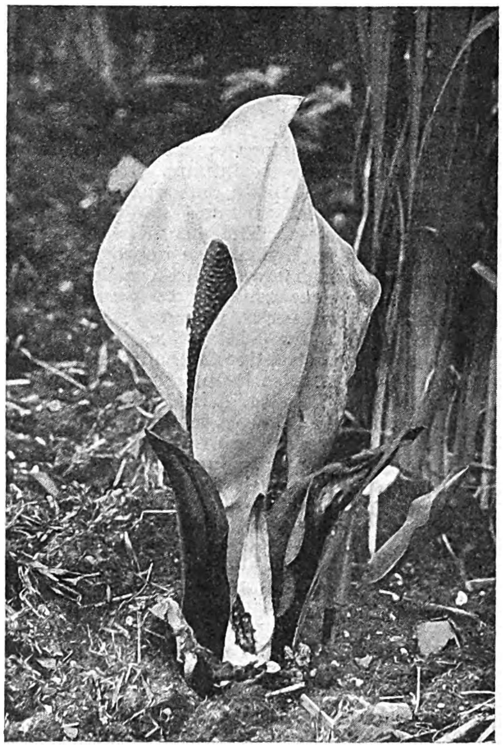

FIG. 220.—LYSICHITUM CAMTSCHATCENSE VAR. ALBUM AT GLASNEVIN.
(see p. 441.)

Parsley.—Where Parsley is wanted during the winter months, a few frames should be made ready and seeds sown in them. The soil surface should be a reasonable distance from the glass, and the lights may be kept off until the weather commences to be cold and wet in the autumn.

Late Peas.—A further sowing of late Peas may be made to supply a late crop. If the ground is dry, the drills should be watered well before the seeds are sown, to hasten germination. When the seedlings are showing give them every attention, and water them frequently if the weather is hot and dry. Earlier-sown plants should be staked before they become too tall.

Late Potatos.—So soon as the haulm is a reasonable height, cultivate between the rows with a "Buco" cultivator, which is very suitable for this purpose, and then earth them up. If the soil is inclined to be poor, give a dressing of an approved Potato manure previous to earthing.

Tomatos.—If these have been well hardened off they may now be planted out, staking each at once, and watering them well.

Thinning Seedlings.—As the seedlings of the various vegetables become large enough, no time should be lost in thinning them, or much injury may result. After thinning, hoe between the rows.

Winter Greens.—So soon as these plants are a fair size, the ground for them should be prepared and the plot divided up for successional crops. See that an early variety is not planted with a late one, for by planting the varieties according to their rotation, the ground will be cleared as they become fit for cutting.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Seakale from root cuttings should be examined carefully, and have the shoots pushing up from the crown reduced to one, as a strong, single crown is most desirable. Keep the soil open and free from weeds so long as it is possible to work among the plants without damage to the leaves. Permanent Seakale beds grown for forcing under pots, etc., should be cleared of all debris, well manured and cultivated. Any attempt to flower should be prevented by removing the growth. Being a seaside plant, salt and sand should be used freely in the soil. A sowing of Parsley should be made about this time to ensure a good winter supply. If possible, sow where a frame can be placed over it, to ward off excessive rain as well as frost; or the plants may be pricked out into frames, but open treatment should be given until severe frost threatens. A sowing of an early Pea, such as Pilot, may be made at an early date should space be available; these often come in just as other fresh Peas begin to get scarce.

Annuals.—Seedlings should be thinned before they become drawn or crowded. The distance apart should, in most cases, equal the height to which they are expected to grow, with two feet as a maximum for the taller subjects. Twigs of Birch, Hazel or Spruce afford admirable support for the dwarfer kinds, but stakes are better suited to Larkspurs, Nigella and similar plants. Sweet Peas should be tied at frequent intervals, to keep the growths upright. The tendrils may or may not be removed in the process, but where plants are trained as single stems it is best to remove them. Watering must be attended to when necessary, and a mulch given on dry, warm soils. No feeding should be given until several well-developed flowers have been produced.

Tuberous Begonias.—These should be afforded larger pots before they become pot-bound. A compost consisting of one part fibrous loam, one part partly decayed leaves, and one part old, flaky manure, with one part of sand and charcoal added, suits them. Water thoroughly before turning them out and pot only moderately firmly. Place the plants in a cold frame, keeping them close and shaded for a few days, with only a sprinkling of water, until the roots are again in action; thereafter do not let them dry out at any time.

Winter-flowering Plants.—Young stock of Euphorbia fulgens, Poinsettias, Jacobinias, Coleus thyrsoideus, etc., for winter flowering should now be rooted. The cuttings selected should be short and fairly firm, and every effort to promote a short-jointed growth made by keeping them near the glass while in heat, and removing them to a cool house or frame when established. Cinerarias and Primulas of all kinds should be pricked off into boxes of light soil so soon as they show the rough leaf; a cold frame is the best place for them now. Keep them rather close and shaded for a few days, after which they may be given open-air treatment, except during very hot or very wet weather.

Watering.—The principal watering of the day under glass, should, for the next month or two, take place late in the afternoon, as plants get more benefit from water then, having the cool night in which to enjoy it. Most growing plants should be syringed freely morning and evening on bright days, and the stages, walls and paths thoroughly damped down. The houses, except those containing flowering plants, should be closed for a few hours as the sun declines, but some air should be admitted again before night.

INDOOR PLANTS.

CELSIA ARCTURUS.

Although this greenhouse plant is by no means well-known, nevertheless it deserves a place in every greenhouse, especially where only a little heat is available, and anyone who has never grown a batch of plants before will be amply repaid, not only by its pretty and showy display of flowers, but also for the length of time it keeps in bloom. It is not uncommon for it to commence flowering in August, and with only three successional sowings, to last until April, and when one recognises how valuable flowering plants are for decorative purposes during the dull period of the year, surely this plant is worthy of consideration.

Anyone starting a batch of plants cannot do better than to commence sowing seeds at once in gentle heat. The seeds should be sown in pots or pans covered with sheets of glass. Prick off the seedlings when ready into small sixty-sized pots, and when established remove them to a cold frame. When ready, transfer them to forty-eight-sized pots, potting them in a moderately heavy compost. For the first week after potting, keep them close and only give a sprinkling of water. Afterwards, admit air freely until the lights may be removed altogether, only to be replaced should the weather become very wet. The plants grow best on a cool base, and should be placed either on an ash floor or slates, or upon an inverted pot, as the roots come through so readily, and when moved they receive a check by the breaking of their roots.

Established plants should be generously fed twice a week with a solution of soot and cow manure in liquid form. A little prepared plant food added is an advantage which the plants readily respond to.

It is a good plan to cut out the first flower spikes, and although this throws the plants back about three weeks, six or seven spikes will come up instead of one although, of course, these are smaller, but the plant presents a much more showy appearance.

The chief essential to be borne in mind when growing Celsia Arcturus is cool treatment. After the seeds have germinated, very little fire heat is necessary, in fact, it is detrimental to the plant, as it causes it to become drawn, leggy and useless. I have known some plants to run up in spite of the cool treatment, but this was due to a poor strain of seeds. *Geo. Barton, Tansley.*

TREES AND SHRUBS.

ENKIANTHUS CAMPANULATUS.

This species may be regarded as the hardiest and most satisfactory member of this small genus of very beautiful shrubs, and is a valuable and extremely attractive subject for planting in rather open woodland. It is now, early June, heavily laden with trusses of flowers, ample proof of its hardiness, for these flowers are produced from the terminal buds of short, spur-like growths of last season's formation, and had to pass through the severe winter—therefore, it may be stated fairly definitely that E. campanulatus, a native of Japan, from which country it was introduced to this in 1888 through the agency of Messrs. J. Veitch and Sons, is quite hardy in this country.

It is a deciduous shrub, seldom more than six feet high under cultivation here, but capable, it is stated, of attaining a height of from fifteen to thirty feet. Of erect, rather stiff habit, its growths are produced in whorls and are, in the young state, smooth and tinged with red. The rich, dull green leaves are borne in clusters chiefly at the ends of the shoots; they are one inch to two-and-a-half inches long, and vary in shape from obovate to oval, usually tapering gently at the base, the margins being finely toothed. The foliage takes on vivid orange-yellow and reddish tints in the autumn, and thereby adds considerably to the decorative value of this shrub.

And the flowers also, although not brightly coloured, impart a charm to E. campanulatus which places it high among flowering shrubs for the woodland, suitable for planting in cool, deep, peaty or loamy soil. The blossoms, produced during late May and early June, in drooping racemes sometimes so shortened as to appear like umbels, have bell-shaped corollas pale cream in colour, veined with red, the five rounded lobes also being tipped with red.

E. campanulatus, which is figured in the *Botanical Magazine*, t. 7,059, is strong-growing when happily established in suitable soil, and in conjunction with other peat-loving plants, may be employed to produce charming effects—subdued with regard to the floral display, but vivid and striking in the autumn when the foliage prepares to depart. *M. W.*

FLOWERING CRABS.

Under the heading of Malus in the genus Pyrus come all the flowering Apples usually known as Flowering Crabs. The majority are more effective in flower than fruit.

I think I should put at the head of the list the garden hybrid P. Eleyi, on account of its flowers, foliage and fruits. It is a hybrid between P. Niedwetzkyana and P. spectabilis, and was named after its raiser, Mr. C. Eley, of East Bergholt, in Suffolk. Its foliage opens almost dark crimson, changing to purplish-green, and is beautiful from spring to autumn. Its flowers are wine-red and borne freely, and equally attractive are the fruits in autumn—like purplish-red Cherries, in clusters. This plant flowers in April and May and is, I think, an improvement on P. purpurea, which flowers a little earlier than P. Eleyi. In gardens where space permits, both should be grown, for P. purpurea flowers most profusely, and its Cherry-like, purplish-red fruits are very attractive in the autumn. The foliage is not quite so large as in P. Eleyi.

P. floribunda stands high in the list on account of its profusion of flowers in the latter part of April. The buds are crimson and the flowers nearly white when fully expanded. It forms a low, very twiggy bush or tree, and a good specimen becomes a cloud of blossom each year, for it never seems to fail to flower freely. Bullfinches appear to prefer the buds to other species in my garden, and even with all the damage they do to the flowering buds, the bushes still give a mass of bloom. Personally, I prefer to grow this as a bush rather than as a standard. There is a variety known as atrosanguinea with deeper-coloured flowers and of rather more pendulous habit, but my experience is that it is not so free in flowering or so effective as the other.

P. Sargentii is a delightful plant for any garden, but especially for small gardens, for it does not appear to exceed six feet in height. Its flowers, pure white, are clustered along its somewhat stiff, horizontal branches. The buds are tinged with pink before opening. In the autumn the foliage turns a rich gold and the fruits, which are borne freely and are about the size of a Pea, become bright crimson.

P. baccata is the true Siberian Crab, but the latter name is generally applied to P. prunifolia, which is a better grower. The two species may be distinguished by their fruits. The fruit of P. baccata has a flat top and an eye forming a cavity, and that of P. prunifolia has a protruding eye. While they are attractive in spring when in blossom, I think they are more so when the fruits are ripening in the autumn. They form tiny Apples of the size of a large Cherry.

P. Malus var. aldenhamensis, raised at Aldenham is somewhat similar to P. Eleyi. The flowers are darker and several days later, and the fruits are not unlike ripe Morello Cherries. Another similar hybrid is P. Lemoinei, which I have only as a young bush, and this promises to be as good as P. Eleyi in flower, but I do not know whether it fruits at all, although there appears no reason why it should not do so.

P. arnoldiana is a hybrid of P. floribunda, and while not being of such strong habit, inclines to be somewhat pendulous. The flowers are considerably larger than those of P. floribunda. P. theifera forms a shapely, small tree, and the flowers, which are white, tinted with pink, give one the impression that it is a Cherry and not a Crab. The small, red fruits are often freely borne and are effective in autumn. P. Prattii has larger foliage than most of the Crabs, and this applies also to P. yunnanensis, which has white flowers and broad foliage which turns a rich colour in the autumn.

I have an attractive flowering variety named Lady Northcliffe, which appears to be a little earlier than P. floribunda, with flowers of a similar colour. The fruiting forms of P. Malus, such as John Downie, Cheal's Crimson, Veitch's Scarlet, etc., should be grown for their flowers as well as their fruits, although probably they are more attractive in the autumn when laden with their comparatively large, highly coloured fruits.

P. Tschonoskii has not yet flowered with me, but it has white flowers tinged with pink. The habit is rather upright-pyramidal and its autumn foliage is very richly coloured.

There is considerable confusion in the three following Crabs—P. angustifolia, P. coronaria var. flore pleno, and P. ioensis var. flore pleno. The flowers are comparatively large, double, soft pink and very fragrant. The latter variety is stated to be of poor constitution—perhaps the choice of the stock on which it is worked might have some effect on it; these flower later than the other Crabs.

P. Toringo (P. Sieboldii) is of somewhat bushy-pendulous habit and flowers later than P. floribunda. The flowers are white. A rare species I have here is P. crataegifolia. Its white flowers appear in June, and its foliage is greyish-green, resembling that of a Hawthorn. P. kansuensis is another rare species, the flowers and foliage of which also much resemble those of an American Thorn.

P. spectabilis is of rather upright habit. The flowers are nearly two inches across, of a pale rose shade. There is a semi-double form of this variety known as Kaido, with deep rose flowers.

P. M. var. magdeburgensis is a very ornamental variety of recent introduction and is of strictly fastigiate habit. The flowers are of large size and rich pink. The only plant I have is as yet small and does not show its fastigiate habit.

P. Zumi is of the same class as P. Toringo; the flowers are pink in bud, changing to white when open, and are in clusters of five or six.

This by no means exhausts the list of ornamental Crabs, but I think I have mentioned most of the best for spring effect. One thing about them is that the majority seem to give a wonderful display of flowers every year, no matter what the weather may be. They are best left alone to form shapely specimens, only using the knife when absolutely necessary. *Prunyrus, Hants.*

SYRINGA VILLOSA AND S. WILSONII.

With so many beautiful varieties of Lilac, chiefly of Continental origin, available, the Syringa species are liable to be overlooked in the ordering of shrub borders and gardens. Yet such neglect is not justified, for among these species are many which, although not possessing the heavy inflorescences of the hybrids or, in some instances, the fragrance, are yet singularly attractive, with such distinct characters as to render them well worthy of inclusion in the most select collections of shrubs. Two such species are Syringa villosa and S. Wilsonii, both of which are flowering freely this season, and at the time of writing are making a grand display.

S. villosa has long been known in English gardens and, for that matter, in American and Continental ones as well, for it is the earliest known of the Chinese species. Père d'Incarville was the first to discover it about the middle of last century, north of Pekin—but it was left to Doctor Bretschneider, about the year 1885, to introduce this lovely Lilac to both Europe and America, which fact, no doubt, accounts for its synonym, S. Bretschneideri, under which name it has been described by several authorities (*Bot. Mag.*, t. 8,292), while it has also frequently been referred to S. Josikaea, and given the title S. Josikaea var. eximia.

S. villosa is quite hardy in this country and forms a grand specimen bush of symmetrical form; it is one of those shrubs which, to be seen at its best, requires to be given plenty of room, for it forms a rounded mound ten feet or more high, and as much across, and therefore requires ample space for free development. Incidentally, it is especially useful for planting in towns where the atmosphere is not conducive to the good health of many shrubs.

Even when not in flower S. villosa is a handsome shrub, forming an unbroken mound of rather pale green, oblong-lanceolate leaves, but at this season of the year it is superb, for the foliage is almost hidden from view by the masses of dense, branching racemes of pale rose or nearly white flowers, the unopened ones being of a deeper, rosy-lilac shade.

S. Wilsonii is of different habit to S. villosa, for, whereas the latter develops into a spreading, rounded mound, S. Wilsonii is of erect, columnar habit, attaining, when fully developed, a height of about fifteen feet.

It would appear that the correct name of S. Wilsonii is S. tomentella, but it is so commonly known under the former name, at least in this country, that the use of the latter would only lead to confusion. Its erect branches are ash-grey, and are furnished with elliptic or oblong-lanceolate, pointed, light green leaves, the flowers, which are small and of wax-like appearance, of palest flesh colour, with deeper pink corolla tubes, being borne in large and dense, erect and rather stiff, branching racemes.

Neither of these species presents any difficulty in cultivation, although S. Wilsonii was slightly damaged last winter, but not sufficiently to impair its display of flowers. Like other species, they flourish in deeply-worked, loamy soil, and benefit by a biennial mulching of manure or humus, which treatment keeps them in active growth. They both make grand specimen plants and may be propagated by cuttings or layers, S. Wilsonii, being rather difficult in the latter respect, owing to its erect mode of growth, care being necessary when bending the branches down during the process of layering. *Kent.*

ALPINE GARDEN.

DIANTHUS SUBACAULIS.

This daintly little alpine Pink is now flowering freely on a warm, sunny ledge, and is very charming. For D. subacaulis forms a compact little cushion of small, narrow, glaucous-grey foliage, and above this are borne, on slender, simple stems up to about four inches in height, small, symmetrically-shaped, rich rose-pink flowers, not half-an-inch in diameter and carried singly on the stems, but produced with sufficient freedom as to form a dainty and attractive, light mound of blossom.

D. subacaulis is not difficult to cultivate. It may be grown in the moraine, but does equally well on a sunny ledge in well-drained, light, loamy soil containing plenty of limestone chips. The late Reginald Farrer in *The English Rock Garden*, declined to consider this Dianthus, which hails from the Dauphiny, as a distinct species, although it is treated as such in the Kew *Hand-list of Rock Garden Plants*.

It is a charming little Pink, not difficult to grow nor, under normal conditions, liable to be lost, and is well worth its place on the rock garden. *M. W.*

PENTSTEMON SIX HILLS HYBRID.

This interesting and attractive hybrid shrubby Pentstemon originated in the nursery of Mr. Clarence Elliott, hence the name of Six Hills Hybrid. There is a very fine plant of it in my moraine, and at present it is in full bloom and very attractive. It is believed to have for its parents P. Davidsonii and P. cristatus. It forms a low, spreading plant with pleasing, glossy, dark green leaves, above which rise a vast number of rather large, lavender-coloured bugles, on stems five or six inches high. It came into bloom here in the last days of May.

P. Six Hills Hybrid is growing here in a well-drained moraine with plenty of sand and chips in the compost, and mulched with whinstone chips; here it is thoroughly at home and has grown amazingly and has withstood the last two winters without the slightest injury. The moraine has a gentle slope to the west. *S. Arnott.*

NOTES FROM GLASNEVIN.

Lysichitum camtschatcense var. album.

The enormous yellow spathes of L. camtschatcense are fairly familiar to growers of hardy plants, but the variety with white spathes (Fig. 220) is less common although no less remarkable. It has flowered in the bog garden at Glasnevin for some years with increasing vigour, and this spring surpassed its previous efforts. Arising from among the green tips of the young leaves the pure white spathes are striking. It almost seems as if this white-spathed plant might be a distinct species, as not only are the spathes broader in proportion to their length, but the leaves differ from those of the yellow-spathed plant, which has enormous, deep green leaves, whereas in the white-flowered variety they are shorter, blunter and almost glaucous-green, especially when young. So far, seedlings from the white variety have not been raised, although last year's seeds are still sound, whereas seeds of the type, or yellow, form grow freely, even germinating around the parent plants.

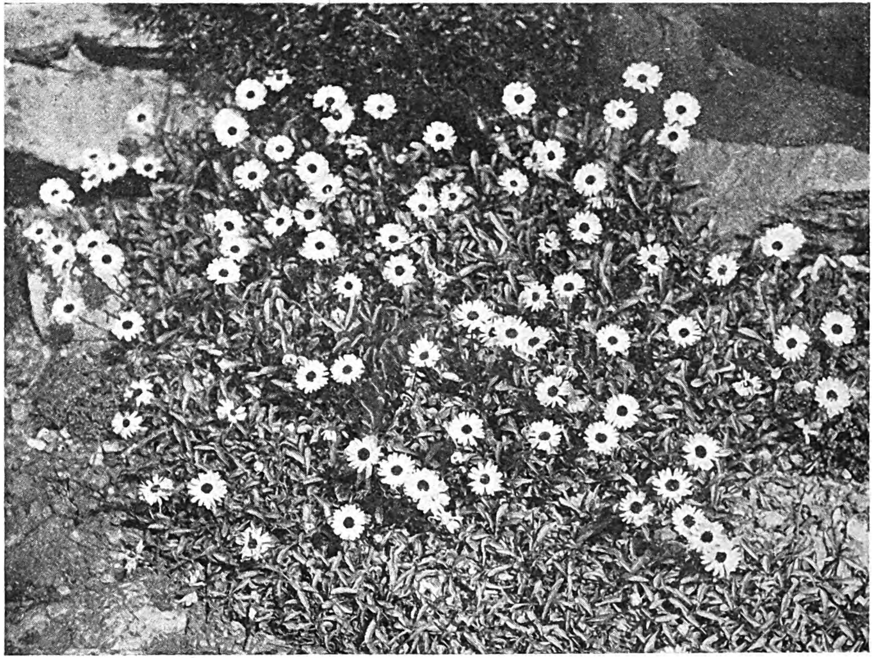

FIG. 221.—ERIGERON LEIOMERUS.

Erigeron leiomerus.

The long spell of dry weather in March, April and May apparently suited this dainty species (Fig. 221) from the mountains of Colorado and Utah. Never before has it flowered so freely, demonstrating well its suitability for exposed dry and sunny positions in the rock garden. Here it is growing in a pocket of rather poor soil close by the path and has been in flower for many weeks, the lavender-blue flower heads rising only a few inches above the leaves which hug the soil. In a genus which contains many beautiful species and hybrids, this is certainly one to be recommended.

Sedum fastigiatum.

This is a Himalayan species of the Rhodiola section, attractive at present by reason of the rich, dark red colour of the sepals and carpels of the female flowers. From a typical woody rootstock the round, smooth stems arise, erect and more or less in a whorl, about six inches high, each terminating in an inflorescence. The fleshy leaves are linear-lanceolate, half-an-inch or so long, deep green. This is a particularly pleasing species which has recently attracted the attention of visitors.

Sedum pilosum.

One of the most enjoyable colour effects in the rock garden at present is provided by a patch of this charming biennial species. The first year it forms attractive rosettes of fleshy, hairy leaves which are now completely hidden by dense cymes of beautiful rose-pink flowers. Although a biennial, this is a desirable plant. Seeds are produced freely and germinate readily, so that by sowing a pinch annually a stock is easily maintained. A sunny position in well-drained soil is essential.

Dianthus caesius var. grandiflorus.

The Cheddar Pink is known in gardens in several forms, including the rather coarse double variety, but in my opinion, the finest is the variety under notice. The flowers, of a bright rose-pink, are almost an inch across, borne a few inches above the glaucous leaves. This came originally to Glasnevin from Mr. A. K. Bulley, of Ness, Cheshire, and is not the least valuable of the many fine and interesting plants we owe to his generosity.

Senecio tyrolensis.

This may be but a form of S. arbrotanifolius with rather more finely cut leaves and neater flower heads, but the brilliant orange-yellow colour is the same. This is a limestone plant of the Southern Alps, according to Farrer, although most botanical works are curiously silent concerning it. An exposed position in well-drained soil seems to suit it. Propagation may be effected by cuttings of the basal shoots. Seeds are uncertain.

Tulipa Sprengeri.

This, the latest of the Tulip species to flower, is also one of the most striking. Reaching a height of eighteen inches to two feet when flourishing, the fiery, orange-red flowers are remarkably effective, particularly when seen in a large colony. It is now flowering on the rock garden here, but the finest colony I have seen grows in Mr. Walpole's garden at Mount Usher, where it has been raised in hundreds from seeds and provides a wonderful display annually. This beautiful Armenian species is worthy of being more generally grown.

Hippeastrum pratense.

I was first attracted by this fine Chilian species at the International Show in 1912, when it was shown in some quantity. It is now in full flower at Glasnevin, in two small beds at the end of the Camellia House, facing south-west. The bulbs have been there for many years now and flower regularly. The orange-red colour appeals to most plant lovers, and the hardiness of the bulbs seems beyond question. I have seen it flourishing equally well on Mr. Barton's rock garden at The Bush, in Co. Antrim, where the climate is like that of parts of Scotland. *J. W. Besant.*

NOTES FROM KEW.

So many shrubs in the outdoor garden suffered last winter from frosts and cold winds that it is doubly pleasing to note and record how well some of the old favourites have withstood the test. I have never seen the Laburnums, the Lilacs, the Pyruses, the varieties of the Common Hawthorn and the Wistarias—to name only five—flowering better.

The Laburnum is one of our most beautiful flowering trees of small size, producing masses of yellow blossoms during the second half of May and in June. The trees are so hardy, easily cultivated and readily raised from seeds, that it is surprising that they are not planted in far greater numbers in shrubbery beds and borders and fringing the woodland.

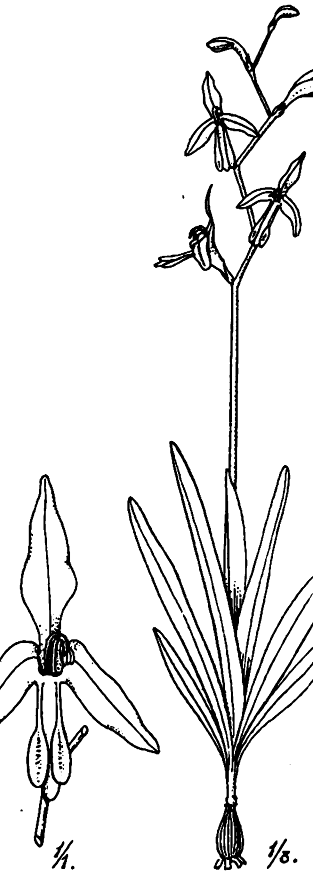

FIG. 222.—SYNNOTIA BICOLOR.

Nearly twenty varieties and hybrids are represented in the Kew collection. A selection of the best for general cultivation should include Laburnum Watereri, L. Vossii, L. vulgare var. intermedium, L. v. var. Alschingeri, L. Latest and Longest, and L. alpinum, the Scotch Laburnum. The last two are particularly valuable because they flower some three weeks later than the varieties of Laburnum vulgare.

Mention must also be made of the remarkable graft-hybrid, Laburnum Adami, which also is flowering very freely this spring. On some trees it may be found necessary to do a little pruning, the Common Laburnum in some cases being inclined to outgrow the purple-flowered hybrid.

The white, pink and red or scarlet varieties of the Common Hawthorn or May are very prominent and attractive on the lawns, in the Crataegus collection south of the Temperate House, and particularly on the banks of the islands in the lake. There is also a great wealth of exotic species and varieties flowering very freely near the Chinese Pagoda. It is only possible to give in these notes a very limited list of the most desirable to plant as flowering trees. These include the varieties coccinea plena (Paul's Double Scarlet Thorn), alba plena (double white), rosea plena (double pink), and coccinea (single scarlet), with Crataegus monogyna var. semperflorens, a dwarf, slow-growing tree or bush, represented by a group of four plants three to five feet high, and covered with white blossoms; C. orientalis, the Oriental Thorn, with distinct, lobed, greyish leaves and masses of white flowers; the Red Haw, C. mollis; C. prunifolia, C. Leeana and the yellow-fruiting Thorn, C. oxyacantha var. fructu luteo.

Most of the flowering Crabs are over or past their best. One notable exception is the Bechtel Crab, Pyrus ioensis var. flore pleno. This has dainty, pale-pink blossoms which are deliciously fragrant and larger than any other Crab, being two to two-and-a-half inches in diameter. Pyrus crataegifolia forms a small, round-headed tree some eight to ten feet or more in height. It is a native tree of north Italy, its pure white flowers and foliage resembling those of a Thorn rather than a Pyrus. The Common Whitebeam, Pyrus Aria, as flowering at Kew at the present time, is a handsome British tree deserving much more attention in our pleasure grounds and parks. Another neglected British tree for open woodland and park planting is Pyrus torminalis, known as the Service Tree.

The Chinese Fringe Tree, Chionanthus retusa, is conspicuous in the Oleaceae collection near the Azalea Garden. A deciduous shrub or small tree, a specimen some six feet in height is covered with snow-white blossoms.

Several specimen lawn bushes of the Chinese Rosa Hugonis are conspicuous with long, arching growths covered with bright yellow blossoms. Large bushes of the Mount Omi Rose, R. omeiensis, are equally ornamental with their elegant, Fern-like foliage and large, four-petalled, white flowers. A large group of the Siberian Rose, R. altaica, in the Rose Dell near the Chinese Pagoda, is a charming sight The creamy-white flowers are three inches across.

The little known Jamesia americana has come through the winter better than most of its near ally, the Deutzia family. A deciduous bush, four to five feet or more in height, it has white flowers, borne freely in small terminal panicles. A native of western North America, it has been cultivated at Kew since 1862.

Very many Spiraeas are in flower; the one of outstanding merit at the moment is a large bush of S. bracteata near the Cactus House. Between five and six feet in height and as much in diameter, the bush is wreathed with rounded clusters of pure white flowers. A native of Japan, the name "bracteata" refers to the small, leaf-like bracts produced on the inflorescences.

In common with several old favourites in the outdoor garden, the severe frosts of the past winter have done no harm to the Wistarias. In fact, all are flowering with, if anything, more than their usual freedom. On several buildings and on the iron, cage-like structure near the Maidenhair Tree, Wistaria chinensis has proved a source of considerable attraction to visitors for some time. About ten or twelve days later in flowering, the lilac and purple blooms of W. multijuga and the white variety alba, have surpassed in attractive beauty the older sort. The branches of the white variety in particular are packed with the long racemes of blossoms on a cage-like structure, near Cambridge Cottage Garden and the Water-Lily House. This floriferous character is largely the outcome of close spur-pruning of the young growths. As the long, twining shoots develop in summer they are cut back several times, at intervals, to within three or four leaves of the base. *A. Osborn.*

SYNNOTIAS.

The genus Synnotia, Sweet, comprises three species of dwarf herbaceous plants belonging to the Natural Order Iridaceae, and the Tribe Ixieae; they are closely related to the Gladioli on one hand and the Ixias on the other. All three species are well worthy of cultivation, and should succeed out-of-doors in warm, sunny localities in Great Britain, in sheltered but open parts of the rock garden in well-drained, rich, gritty loam and leaf-soil. A handlight should be placed over the plants so soon as the leaves show signs of decay, in order to ripen the corms; it should be allowed to remain over them until growth recommences in the spring. In cold localities they should be grown in pots of rich, gritty soil, in a greenhouse from which the frost is just excluded. When growing in a state of nature in their native habitats, Synnotias are usually found among short herbage in gritty or rocky soils in hilly situations.

S. bicolor, Sweet (Fig. 222).—This delightful species was introduced into this country in the year 1786, but is now probably lost to cultivation, The ellipsoid or ovoid corm which is buried about one inch below the surface of the soil, is about as large as a Filbert, and is coated with finely-reticulated or honeycomb-like fibres of a pale or darkish brown colour; it produces a stout, greenish-white stem about one inch long, somewhat swollen where it emerges from the corm; this portion is buried beneath the soil; it bears from six to eight sword-shaped, blunt leaves, from six to eight inches long, with a distinct midrib and many delicate longitudinal veins. They are produced from the top of the short stem in a fan-shaped manner, and are of a delicate pale green colour; there are usually numerous, small, dark purple blotches and bars at the base of each leaf.

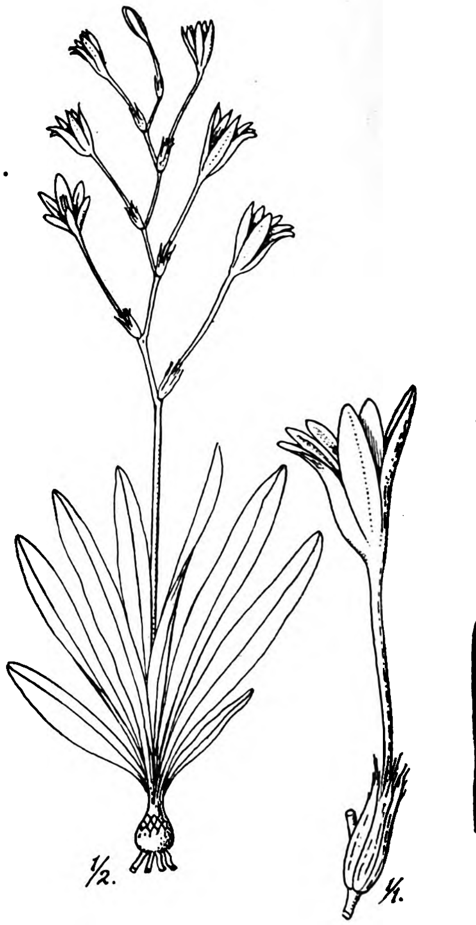

FIG. 223.—SYNNOTIA METELERKAMPIAE.

The flower stem is from six to eighteen inches long, and is slender, grass-like and zig-zagged above among the flowers, which are borne in a loose spike; they number from two to six, and are somewhat widely separated. The spathe-valves or bracts which protect the blossom when it is in the bud stage are oval, thin in texture, about half-an-inch long and deeply lacerated towards the apex; they are green at the base and brown at the tip. The curiously-shaped but attractive blossom has a cylindrical tube about half-an-inch in length, dilated and broadly funnel-shaped at the mouth, where it is divided into six somewhat unequal segments measuring about one-and-three-quarters-of-an-inch across. The uppermost segment is oval, blunt, undulate and tapers to a broad stalk below; it is carried quite erect; the two side segments are similar in shape, but do not taper so much; they are spreading. The three lower segments are long and narrow; the two outermost are shaped like elongated tennis racquets, and the centre one has a broad stalk. In colour the blossoms vary from very pale yellow to white shaded with violet or purple; the three lower segments are rich yellow and project forward like a lip or platform.

The variety Roxburgii, Baker, has the outer coating of the corm composed of fine threads, and the blossoms are lilac-purple throughout.

The type and its variety are found in hilly country in the Cape, Paarl Malmesbury and Van Rhynsdrop Divisions of Cape Colony.

It is also known under the names of Gladiolus bicolor, G. galeatus, Sparaxis bicolor and S. galeata. It is figured in the *Bot. Mag.*, t. 548, under the name of Ixia bicolor.

S. Metelerkampiae, L. Bolus (Fig. 223).—In habit and leaf this handsome species closely resembles the preceding, but differs from it very much in the shape and colour of its blossoms. The ovoid corm, which measures about five-eighths-of-an-inch in diameter, is coated with stiff fibres which form a very pronounced honeycomb-like pattern on its upper half; it is buried not more than half-an-inch below the surface of the soil, and produces from its base about half-a-dozen stout, tough, fibrous roots. The blunt, or slightly pointed, pale greyish-green, sub-erect, sword-shaped leaves, some half-a-dozen in number, are produced in a fan-shaped manner from a very short stem, which is entirely buried beneath the soil; they are from two to four inches in length, about half-an-inch in width, and are frequently wavy on their margins. All their nerves, except the centre ones, are quite inconspicuous.

The flower stem, which is sometimes branched low down, is from six to ten inches tall, grass-like, erect below, zig-zag among the blossoms, which number from nine to twelve, borne in a loose raceme. The spathe valves or bracts are very conspicuous on account of their very pale green ground colour, and pale chestnut-brown shadings. They are oval in shape, about three-quarters-of-an-inch long, and are much torn and lacerated upwards.

The richly-tinted blossoms have very slender, cylindrical, slightly curved tubes, about one-and-three-quarters-of-an-inch in length, which very suddenly expand near the apex into funnel-shaped mouths. The segments of the blossom are very unequal in size, and are carried much more erect than those of the preceding species; the uppermost segment, which is by far the largest, is broadly oblong, with incurved margins, and is carried more or less erect; the two side segments are rather similar in shape, but are smaller, and the three lower ones are smaller still, narrower, and have undulate or incurved margins. The blossoms, which measure about two-and-three-quarter inches in length, including the tube, and about three-quarters-of-an-inch in width, are of a rich violet colour, except the three lowermost segments, which are bright orange, bordered with violet; the orange colour becomes pale towards its centre. This desirable species has not yet been introduced into this country, but is in cultivation in South Africa. It is apparently a very local species, and was originally discovered near Eendekuil, in the Clanwilliam Division of Cape Colony, growing under the same conditions as the preceding species. It is figured in *The Flowering Plants of South Africa*, t. 97.

S. variegata, Sweet.—The corm of this charming plant is about half-an-inch in diameter, and is coated with coarse fibres arranged in a honeycomb pattern. The leaves, from six to seven in number, are produced in fan-shaped manner from a short underground stem; they are sword-shaped, from three to six inches in length, blunt or slightly pointed, and of a pale green colour. The blossoms, which number from three to six, are arranged in a loose spike on a slender flower stem from six to twelve inches tall, in the same manner as those of S. bicolor. The spathe valves or floral bracts are oval, thin in texture, and lacerated towards their tips.

The richly-tinted blossoms, which measure about two-and-a-quarter inches in length and one inch in width, have a cylindrical tube as much as one-and-a-half inch in length, which dilates suddenly near its apex into a funnel-shaped mouth; the upper segment is oval, about half-an-inch in breadth, and is carried more or less erect, while the other five segments which are not so long, are only three-eighths-of-an-inch across. The ground colour of the blossom is dark violet with rich yellow shading on the three lower segments. It is probably closely related to the preceding species, and is found in sandy soil among other dwarf vegetation, and like S. Metelerkampiae, is apparently confined to the Clanwilliam Division of Cape Colony. The plant is also known as Sparaxis leuto-violacea (Eckl.) and S. Wattii (Harv.); it is figured in colour in Sweet's *The British Flower Garden*, t. 150. *A. W. Darnell.*

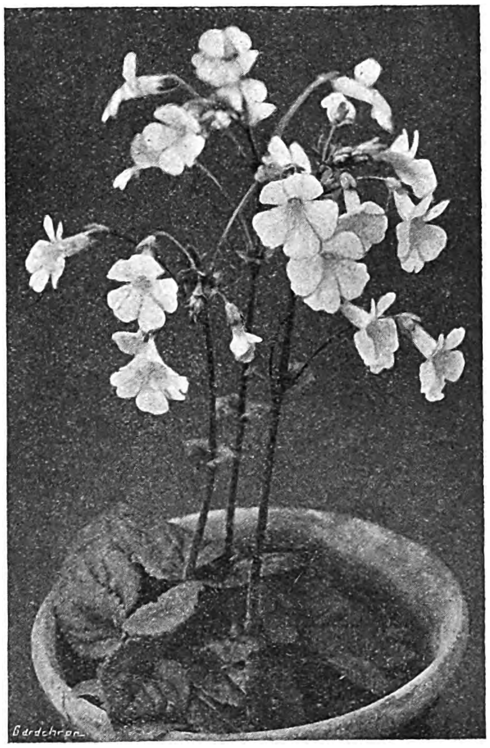

FIG. 224.—OURISIA ALPINA.

PLANTS NEW OR NOTEWORTHY.

OURISIA ALPINA.

The plant shown by Captain McEacharn at the Chelsea Show was Ourisia alpina, Poepp. and Endl. (Comber 1,127), correctly named and reported in your issue of May 25 (p. 385). Unfortunately, the photograph reproduced on p. 391 (Fig. 199) was of Ourisia coccinea or O. elegans (I am not sure which).

You will see from the print that I enclose (Fig. 224) O. alpina is entirely different, the flower being noticeably shorter and more open at the mouth, while, as you state, the colour is pink, not scarlet as in the longer-tubed species.

Another fact which crops up in this connection, and is not generally known yet, is that the Ourisia coccinea commonly grown in our gardens is not true O. coccinea, Pers., but Ourisia elegans, Phil. The true species was shown in May last year and gained an Award of Merit. This was raised from seeds collected by me in 1927. Both species have been lumped under the name of O. coccinea, but are quite distinct. *Harold F. Comber.*

OURISIA MACROCARPA.

Many visitors to the recent Chelsea Show were interested in the fine display of this novelty in the Bodnant collection. I have not had the species long enough to enable me to state anything regarding its behaviour out-of-doors, but I am assured it is quite hardy, and it certainly promises to be a most useful garden plant. Put out in a cool, fairly rich loam in part shade, my specimen (Fig. 225) has made a clump over a foot across of its close-set foliage. The heart-shaped leaves, which are dark green, leathery, bullate and evenly serrated, are from two inches to three inches long. They are glabrous on both sides, but the stalks are hairy and these, as well as the flower pedicels, sepals and leaf margins, are stained with claret colour. The flowers, a good firm white with a yellow throat, are well over half-an-inch across and, individually, rather suggest those of a Nemesia or small Streptocarpus. These blooms, whose whiteness is accentuated by the dark pedicels and calyces, are borne in ample whorls some three inches or more across. As the flowering stalks, rising to about one foot, bear several of these wreathes of blossom in succession, the flowering period is continued throughout the spring and the plant looks like carrying-on well into summer. I understand that the Bodnant stock (Fig. 213, p. 421) was raised from collected seeds sent direct from New Zealand, and the Hon. H. D. McLaren informs me that he has found the species a most reliable garden plant. It is certainly one of the most attractive of the Ourisias that has come my way. *A. T. Johnson, N. Wales.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXIII.—A Fresh Start.

We had now to decide on a new plan of action, one in which the Mishmis would co-operate, since without them we could do nothing. Whatever we decided to do must be done quickly, or we would miss the most valuable part of the season; in spite of our early start from the plains, and the comparatively short distance we had to travel, we were now, date for date, worse off than I had been in 1926, when the situation had looked black enough! We discussed many plans during the next two days, but the simplest appeared to be to try to reach Kaso, a fine peak over 15,000 feet high, which lay far back on the Delei-Dou divide, but directly above the village where we had our camp. Everything depended on the Mishmis. I called up the Gam, and although he insisted that there was no water on the mountain, he very sulkily promised to produce two dozen coolies for us. The next thing was to find a camping ground, as high as possible. As to the route, from the village we could see a path going steeply up the shoulder in the direction of the mountain, and on May 19 we started out to explore it.

The ridge was precipitous, but open, the thick forest which clothed the sheltered flank ceasing abruptly along the crest; the exposed flank, which faced due south, was covered with grass, Bracken, and scattered bushes, with bulging outcrops of bare crystalline rock, and was now chrome-yellow with a species of Piptanthus. Climbing up the ridge, we noted the trees along the edge of the forest: Tsuga and with it Magnolia rostrata and Rhododendron sinogrande, Heptapleurum and other Araliaceae, Oaks, Enkianthus himalaicus (Fig. 226) and Acer. At about 8,000 feet we began to find Rhododendrons in flower, including fine specimens of R. megacalyx, with six or seven blooms on a truss. This is a larger form than the plant from the Tsangpo gorge, with smaller, less rugose leaves; it ascends to nearly 8,000 feet in the Delei valley, but does not look constitutionally hardy. Here, too, we met with the first specimens of Larix Griffithii, which ascends to the tree limit at 12,000 to 13,000 feet, but does not form forests by itself. Other Rhododendrons were a gnarled, smooth-barked tree 'Thomsoni' with large trusses of small, purple flowers, just over; a big-leafed, bushy 'Maddeni,' and several epiphytic species including the beautiful, fragrant 'Edgeworthii' (Fig. 227) found in the Seinghku valley in 1926. Other plants were Ilex nothofagacifolia (Fig. 228), a red-flowered Schizandra, and, on the rocks, Cassiope selaginoides and a pink-flowered Vaccinium. But, perhaps, the best thing on the ridge was a small, tree Gaultheria, its bursting leaf-buds squirting jets of scarlet fire into the massed flowers which were sewn tightly along the branches like cream beads. On the way down the ridge, I found a large, foetid-flowered Aristolochia. From the botanical point of view the first reconnaissance was a success; but we found no possible camping ground.

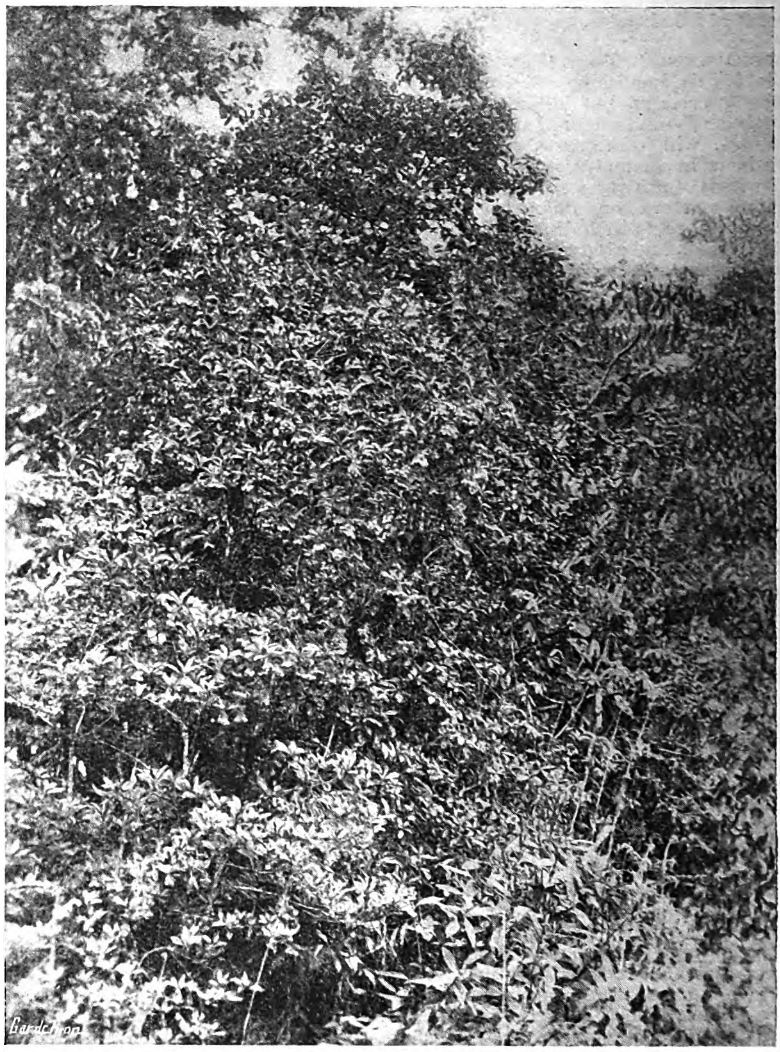

FIG. 226.—DENSE THICKET AND FOREST, WITH ENKIANTHUS HIMALAICUS IN THE FOREGROUND.

Three days later we tried again, Buttercup having volunteered to spend a night on the ridge and explore the path so far as possible. After reaching the point on the ridge where we had turned back before, we entered the rain forest, and again climbed very steeply, until at about 10,000 feet we reached a place where the ridge, changing direction and descending slightly, widened out momentarily at the corner; here, beneath a canopy of big-leafed Rhododendrons, was a possible camping site. The next problem was water, and needless to say, it did not grow on the ridge! This was Buttercup's real quest; and having seen him safely housed in a cosy corner, with blanket and food, and a supply of fire-wood, I returned to the valley.

Next day it was again wet, so it was evident that Buttercup was having an uncomfortable time, and also that he would get no view of Kaso; however, his object was to find water, and, if possible, to reach the alpine region; and he turned up to a late tea that afternoon, and reported. As to the path, he said that it continued indefinitely along the ridge up and down through the forest, and over the cliffs, but that it was hard going in places, as no one had been along it this year, and the snow had weighed down the Bamboos, almost completely blocking it. As to water, he had found several trickles sliding down rock faces or dripping from cliffs, and had reached melting snow, where pools lay in hollows even on the ridge; but he had found no certain and inexhaustible supply anywhere near our camping site. Finally came the botanical report, and here Buttercup opened his rucksac and produced the goods; so I spent a happy hour. Amongst several sprigs of Rhododendron were a 'Sanguineum' with deep port-wine red flowers and a 'Saluenense' with purple flowers, like those of R. calostrotum. Amongst the Primulas were P. vernicosa, a small, purplish-flowered 'Auriculata' from the cliffs, and a charming 'Denticulata' with mops of fragrant, mauve flowers; seeds of this last were collected in the Di Chu valley in 1926, before ever I saw the flowers—which was lucky, for I got no seeds of it in the Delei valley. But the most interesting plant which Buttercup brought back was one which, at a first casual glance, I passed over as a Lloydia; but so remote from the truth was this, that when I looked closely at it, I confessed that it was probably an Omphalogramma! I was certainly on the right track there; but when later in the season, I saw the fruits and seeds, it was evident that it would not fit into that genus either, although it was more Omphalogramma than Primula. It was, in point of fact, a Bryocarpum.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, and 25; and June 1, 1929.

The position was now thus. We had found a possible camping ground in the rain forest at about 10,000 feet altitude; there was a path up the ridge which, it was now reasonable to assume, continued to the alpine region, and there were flowers. But there was, at the moment, no water; two or three fine days, and the sources found by Buttercup, none of which lay close to the camp, might vanish; the monsoon *might* not break for a fortnight. However, we decided to risk it; we must either climb a mountain here, and that soon, if we wished to catch the June flowers, or abandon the Delei valley and try elsewhere—a counsel of despair.

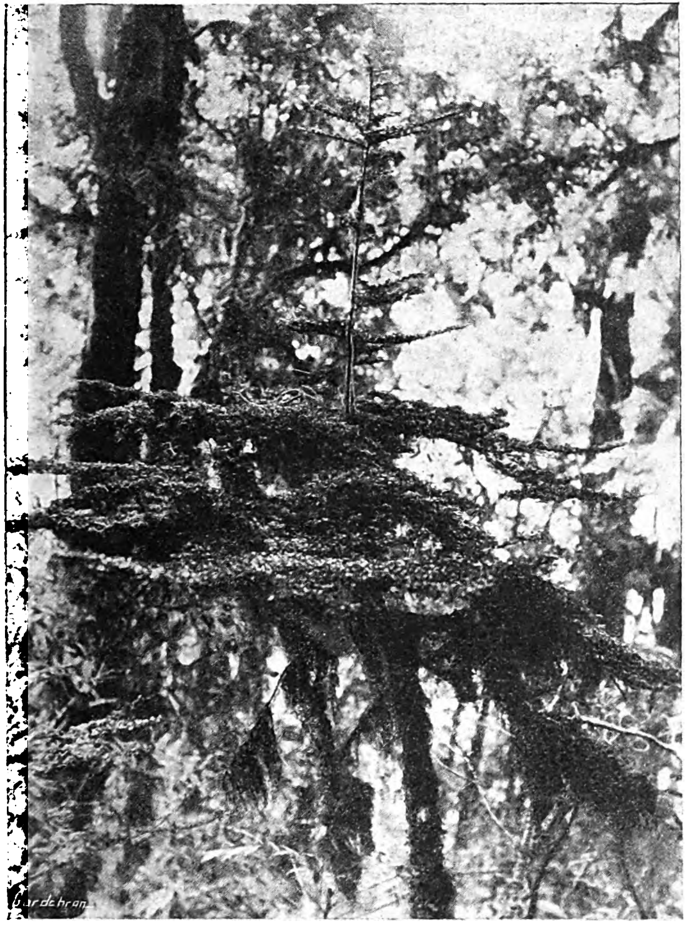

FIG. 227.—ILEX NOTHOFAGACIFOLIA (SHOWING THE CURIOUS TABULAR ARRANGEMENT OF THE BRANCHES.

For the next five days it rained continuously, until I began to think the monsoon had broken already. This would have assured the water supply, but until it turned fine, the coolies could not climb the steep, slippery path up the ridge. All this time I was in a fever of doubt as to whether the Gam would keep to his promise. Meanwhile, we were greatly cheered by the arrival of coolies from Denning, with supplies and mails.

May 28 being fine, we summoned the Gam and made arrangements to start next day. I offered a wage much in excess of that paid to coolies in administered territory (it would have been sheer waste of time to offer less). The Gam promptly raised it, as I knew he would, and I as promptly accepted; so that was fixed with the minimum of friction. Next day we were early on the move. Soon the Gam arrived and then the coolies began to wander in; but by the time we were ready to start we were still ten short of the full complement. The Gam said no more would arrive, but that he would bring the remaining loads up next day; so we left all the rations, stores and spare parts behind, taking food for three days only, and when the sulky Mishmis had had their usual wrangle with us, we actually started. Leaving all the rations behind offered one more hostage to fortune, but we had to take risks.

We now found that the inhabitants of the next village, who had done their best to dissuade us from going, and our coolies from carrying loads for us, had driven spiked Bamboos into the path, in the hope of laming some of us; they were furious at the expedition because we were poaching on their game reserve. However, we had no casualties. The climb proved all we expected for the coolies, and it was late in the afternoon when we arrived at a waterless camp; I was knocked out by a fever attack and did not reach camp until nearly dark. The coolies, having no water, went down the ridge the same evening, but we had brought up two petrol cans of water, sufficient for immediate needs, if zealously rationed.

On the way up the ridge, I noticed that the flowers of Magnolia rostrata, which had been in bud nine days ago, were already over! Five days' rain, of course, had something to do with this, but still — ! I had seen a couple of trees in bloom in the forest, for the first time, and was terribly disappointed with this much-talked-of species. The leaves are so big, and the white flowers, at the ends of the branches, so small, that except under very favourable conditions, they can scarcely be seen at all. The tree itself, which may grow a hundred feet high, with leaves twenty inches long and six inches wide, is seen at its best in April when the leaf-buds are bursting, and in November when the leaves are falling to expose the red, Pineapple cones.

Arrived at our camping place we had to clear the ground a bit before we could put up the tents. Then we rigged up baths with canvas sheets to catch the rain water from the tent flies; but scarcely any rain fell for several days, and we were dependent on a precarious supply from Buttercup's well, which was twenty minutes' journey along the ridge. This was quickly exhausted, and then we had to go to the water cliff, about three quarters of an hour up the ridge, and leave a bucket there to be filled by the constant drip from above. Our Mishmi interpreter went once a day for water and returned with a petrol can full; about ten days later I found a spring right below our camp, and not far down the face, so we made a path to it.

Immediately afterwards the monsoon broke in earnest, and after that we had no more difficulty, as our reservoirs were always overflowing! True to his promise, the Gam returned next day (May 30) with ten coolies, bringing up the remaining loads, so now we were in a position to stay here six weeks. Before going down, the coolies built us an open hut, roofed with bark, where we could have a fire, dry our clothes, and eat our meals in moderate warmth and comfort, without filling our tents up; and here we lived by day, except when the wind blew the rain and mist right through the *basha*, or the fire smoked too badly, or the roof leaked everywhere, or we could not keep the fire in at all. For better or worse, we were now committed to the Delei valley, and to a small portion of one mountain; so we had to make the best of it. *F. Kingdon Ward.*

CHILE AND THE ANDES.*

No. XII.

It was a day or two before we all moved out to the farm. Meanwhile a Dutch steamer came into the harbour with a cargo of pedigree

---

* Previous articles on Mr. Clarence Elliott's expedition were published in our issues of November 12 and 26, December 10 and 24, Vol. LXXXII; January 7 and 28, Vol. LXXXIII; July 28, Vol. LXXXIV; March 28, April 6 and 20, and May 11, Vol. LXXXV.

Freesian cattle, bound for the agricultural show at Santiago. The "King" went on board and bought to the extent of £1,000—two cows, two heifers, and about a ton of pedigree bull. They were brought off in a lighter, and hoisted on a rather inadequate crane. The bull was tied up in a ramshackle shed which he at once demolished, and just as he seemed to be getting into form, and was looking round as though to destroy Coquimbo itself, the "King" took charge, and with an amazing display of quiet nerve, got the bull to a great baulk of timber, and had him securely fastened before he knew what was happening. A very good show, which we watched from a carefully chosen strategic point. The "King's" views on imported cattle in relation to foot and mouth disease were interesting. He told me that Chilian farmers prefer Dutch to English cattle, because, owing to our policy of killing, to stamp out the disease, our cattle have acquired no sort of immunity, inherited or otherwise. They are particularly prone to take the disease, and have it in a severe form when they come into Chile, where foot and mouth disease is rife. Continental cattle, on the other hand, enjoy, he told me, a certain immunity, and take it less readily and less violently. Imported British cattle are disabled, often permanently, and always for a very long time, while imported Continental cattle, as a rule soon get over it. The enterprise of the Dutch breeder who had sent out this consignment, of his cattle was impressive. So far as I remember, there were between forty and fifty beasts. They were splendidly housed on board, arrived in wonderful condition, and were fetching excellent prices when I saw them later at the Santiago Show. The owner had sent out an attractive booklet with photographs of the animals and with their records and pedigrees printed in Spanish.

But to get back to plants.

In a deep gorge near the town, we found Alströmeria violacea ? (C.E.74), an extremely handsome species growing three feet tall, with wide, ample heads of very large flowers of a beautiful rose-lilac. The two upper segments were golden, flecked with crimson. The gold against lilac is, perhaps, a lapse from perfect taste, or a not very happy experiment. Who can say. Yet I was very pleased when I found, one afternoon, a clump of this striking species growing on a steep, sunny scree, with a sprinkling of last year's seeds lying about at its base. I settled down for an hour or more and picked up seeds one by one. I have heard now and then gentle murmurings that a fault of plant collectors is that they send home such miserably small packets of seeds of some of their finds. I would like to plant the murmurers on a rough scree, at a slithering angle, to scramble among loose stone and Cactus thorns, to pick up, one by one, last year's seeds of Alströmeria! There were Cactus thorns not only among stones I scrabbled in, but among stones I sat and kept slipping on!

Along the shore of the bay were several good things, especially a beautiful Malvaceous plant (C.E.81), and a dwarf, herbaceous Solanum, Solanum heteranthemum (C.E.82). The Mallow grew about two feet high, with wiry stems, grey, felty leaves, and mauve, Almond-scented blossoms, large, and of exquisite satin texture. I fear it is going to be very difficult in cultivation. Solanum heteranthemum grew about twelve to eighteen inches tall, with fragrant lilac flowers, and the general appearance of a dwarf, very floriferous and much improved Polemonium coeruleum with lilac flowers. Pasithea coerulea was superb on the hills about Coquimbo, growing five to six feet tall, with graceful, yard-long, branching spikes of brilliant blue. We collected plenty of seeds, which, with me, have germinated badly, although elsewhere they have done well. In Mr. Spedan Lewis's garden, plants from my seeds have already flowered and made their appearance at the R.H.S. Hall. Pasithea is not, of course, new to cultivation. Mr. Bowles told me that for years he has grown and flowered it in a warm wall-sheltered border in the open, and in late autumn Mr. A. G. Hadden sent me seeds from plants in the open in his garden at Porlock. The plant, however, is rare and very little known. Except in very favoured districts, I believe the best results would be obtained by planting it out in a border in an unheated greenhouse.

On the same hills, with Pasithea, we found seedling plants of Tecophilaea violaeflora, far more lusty and vigorous than any we had seen further south. They were six and nine inches tall, and carried four and five capsules on a stem. A most attractive plant was C.E.68—Bahia ambrosioides. It grew in rocky places on the hillsides, with the erect, sub-shrubby habit of the common Rue, in fact, it looked like a singularly beautiful Rue with creamy-white flowers. Two good finds which my companion made in the Coquimbo hills were Tropaeolum brachyceras, a charming, frail climber with short-spurred golden flowers, and Calceolaria picta, a graceful herbaceous species, eighteen inches tall, with a loose shower of rose-pink flowers spotted with crimson. Both were very scarce, and we failed to secure seeds of either.

A curious and interesting shrub at Coquimbo was Porlieria hygrometrica. It grows six to ten feet tall, very rigid and erect, with stiff pinnate leaves of a jade green. Reicher, in his *Flora of Chile*, states that it has been almost exterminated for the sake of its timber, but it was still very abundant in the hills at Coquimbo. Willis in his invaluable *Flowering Plants and Ferns*, states that "the leaflets spread out horizontally at night, but in the day fold up in pairs, reducing transpiration." We took special note of this, but found that exactly the reverse was the case! *Clarence Elliott.*

PROBLEMS OF PLANT LIFE.*

(*Continued from p.* 280).

II.—The Mystery of the Cell.

Everyone is aware in these days that plants of every shape, size and form, from the tiny Duckweed to the giant Water-Lily, or the dwarf Willow to the mighty Oak tree, are made up of cells. We are, indeed, so familiar with this commonplace of botany that we wonder there ever could have been a mystery of the cell. Yet so it is. The story of cytology, as this branch is called, is in point of fact a very wonderful one. The cell may be called, and in truth has more than once been spoken of, as the unit of life; for animal tissues as well as those of the plant are simply an agglomeration of cells, Whether we take the pollen grain or the petal. the leaf or stem, the root or fruit of a plant, every part is built up of cells, just as is the muscle and nerve, cartilage and bone of the human body. All this is the revelation of the microscope, and before that wonderful instrument was invented, the knowledge of the cell was of the most rudimentary character. When, however, the minute forms of life which are found in water came to be magnified, men began to form a totally new idea of the way in which plant and animal organisms were built up. It took a long time, it is true, for the theories to be tested, and facts to be demonstrated. Transparent growths, such as Algae, for example, could easily be studied, and their structure understood, but when it came to thick leaves, dense tissues, and solid wood, the case was different. Step by step, however, the biologist pressed on his way, removing as he went all the obstacles which beset his path, making thin sections, clearing and staining, until at last the truth stood revealed, and the incontrovertible verdict could be pronounced that all life was built up of, or consisted in modifications of, the cell.

Cytology, then, is that branch of botany which concerns itself with cell-structure, and a very wonderful subject it is. Looking at one of the unicellular organisms, such as Euglena, for example, with which every microscopist is familiar, it would seem to be an easy thing to define a cell. It appears to be a cyst, with a gelatinous material for the outer covering, and a content of a more or less fluid substance, which may be colourless or otherwise. But what appears so simple at first sight soon proves itself to be a very complex thing, and when we pass from the unicellular organism to one which is composed of a multitude of cells, one pressing upon the other, and each serving a different end, the task of defining the cell becomes one of great difficulty. Theories were formed, revised, discarded, and again introduced as new facts came to light, and means of investigation were perfected, and a vast army of workers have added their individual grains of knowledge to the building up of a science which to-day fills us with wonder.

One may, perhaps, take the researches of Malpighi, dating from the middle of the seventeenth century, as laying the foundations of their great superstructure. A good summary, not only of Malpighi's discoveries but of the history of cytology, may be found in *The History of Biology*, by Nordenskiöld, which has recently been published by Messrs. Kegan Paul, but this is a work which it is not possible for everyone to obtain.

Among English botanists who were able to render great service in the early days of modern biology may be mentioned Robert Brown, whose discovery of the nucleus may be regarded as epoch-making. The nucleus may be termed the soul of the cell, unless, indeed, we reserve that description for the nucleolus, which is the inner sanctum, the very holy of holies of the plant or animal tissue.

Another name which stands in the forefront is that of Schleiden, who was born in 1804, and in 1838 put forth the question, "How does the cell arise?" He was able to carry forward the work of Brown, and to him we owe the discovery of the nucleolus. So minute is this body that it was impossible to anticipate its discovery until microscopic technique had been brought to a high state of perfection. As Schleiden built upon the foundation laid by Brown, so Schwann built on the superstructure of Schleiden, and affirmed that one common principle of evolution is laid down for the most highly differentiated parts of animal and vegetable organisms, and that this principle of evolution is the formation of the cell.

Schwann held some views which did not commend themselves to later students, but upon his main thesis these workers have been able to formulate a conception of the phenomena of life as a whole, and it has been stated that without Schwann, Darwinism could hardly have been victorious. Mohl's researches resulted in a fuller and truer idea of the cell-nucleus than that held by his distinguished predecessors, and at the same time Nägeli, working on the structure of pollen grains in flowering plants, was able to give a very exact account of the division of the nucleus. He also discovered what he called the transitory cytoblasts, which have since received so large a share of attention as chromosomes, although it remained for others to follow out their full course of development and give them their true interpretation.

When we come to Darwin, we find the theory of the cell receiving a new interpretation. He believed that every cell gives off minute atoms or germinules which, being reunited to form sexual germs, give rise to the resemblances which exist between parent and offspring. This theory, known as pangenesis, has not received support in more recent years, but a further paper on Mendelism and heredity will be necessary to enable us to deal with that branch of the subject. It is curious to note that Haeckel, with all his aggressiveness, held a view respecting the structure of the cell which was at variance with fact—the view, namely, that certain single-celled organisms, which he called monera, were destitute of a nucleus. This suffices to show how difficult a subject for research the cell has been. Microscopists will appreciate what a vast improvement in methods of study was brought about by the invention of the microtome. Under the old methods it was Schultze, perhaps, who brought the study of cytology to the highest degree of perfection. Along with him may be mentioned Strasburger, whose *Practical Botany*, edited by Professor Hillhouse, of Birmingham University, was for many years an invaluable text book for English students.

---

* The first paper of this series appeared in our issue of April 13, p. 280.

In our next paper, in which we will give a glance at the subject of plant fertilisation, we shall be able to derive help from the foregoing notes, while they will serve as a starting point for some further investigations. *Hilderic Friend.*

NOTICE OF BOOK.

Hair-Dyes and Agriculture.

A book on hair-dyes and hair-dyeing is not only a novelty, but the book by Mr. H. S. Redgrove, a chemist and botanist whose name is known to readers of *The Gardeners' Chronicle*, and Mr. G. A. Foan, a practical hairdresser, is very welcome; for, in spite of the fact that hair-dyes are now used by an ever-increasing number of devotees of beauty and fashion, no book dealing with the subject in a scientific manner has hitherto been produced, at any rate, in English. Moreover, the book in question,* in addition to very full information concerning the composition of the various preparations used for dyeing the hair and the best methods of applying them, also deals in a most interesting and helpful manner with the structure of the hair, and with various questions relating to its hygiene, many practical hints being given on how to avoid premature greyness.

From hair-dyes to agriculture is not so far a cry as might appear at first sight. In spite of many researches which have been carried out to discover suitable substances for colouring the hair among the synthetic coal-tar dyes, and which are detailed in the book, certain of the older dyes obtained from plants remain the safest and best. This is especially the case with Henna, which is, however, often mixed with deleterious substances. Henna (Lawsonia alba) is extensively cultivated in Tripoli, India and Egypt to meet the big demand for the dye for cosmetic purposes, and the authors deal very fully with the botany and cultivation of the plant. Among the numerous illustrations, two of Henna are included, one showing a Henna plantation, the other the plant in bloom.

The two Chamomiles used in hair-dyeing, Anthemis nobilis and Matricaria Chamomilla are also carefully described and figured. Other dyes of plant origin dealt with include Indigo, Logwood, Fustic, Catechu and Quercitron, the chemistry of the various substances and their action on the hair being most lucidly explained. Many formulae for hair-dyes are given, including some especially adapted for dyeing false hair or postiche, for which purpose the vegetable dyes are particularly useful. The whole constitutes a volume as interesting to the general reader as it is, we should imagine, indispensable to the professional hairdresser. It should make a special appeal to those readers interested in the question of the chemistry of plant products. The book contains a very complete index and a useful bibliography.

FUEL AND HEATING.

The following remarks on fuel and heating are inspired by some well-reasoned notes in recent issues of *The Gardeners' Chronicle* on the production of crops in unheated greenhouses. Some of your correspondents have shown how useful glasshouses may be without artificial heat, but, however this may be, most growers will admit that their full economic value can only be utilised when reasonable heating is practised. Bearing in mind that the price of fuel is both actually and relatively higher than in pre-war times, it becomes more and more important that it should be purchased and used intelligently and economically. It would appear that the average gardener pays little attention to this matter and the waste accruing from this neglect must be very considerable.

The old adage that the cheapest article in the market is the dearest in the long run is often exemplified in the purchase of fuel. The value of fuel depends not on its weight, but mainly on the number of British thermal units (B.T.U.) it is capable of producing, and therefore price per ton is not the sole consideration. As most of the greenhouse heating in this country is by the use of coke as fuel it may be worth while to consider the production and relative values and uses of the various specimens which answer to this name in the market.

Coke resembles some other articles of commerce in that it lacks uniformity, but for horticultural purposes there are two main classifications—(1) furnace coke, (2) ordinary gas coke, both of which may vary considerably in heating power within their own groups. Generally speaking, however, gas coke is more uniform in heating power than furnace coke, as an average sample will yield at least from 12,000 to 12,500 B.T.U.'s per ton, whereas the yield from furnace coke varies between 10,000 and 13,000 B.T.U.'s per ton, the latter figure being very exceptional. It has to be remembered that the builders of so-called coke ovens have in mind the separation of sulphate of ammonia, tars, dyes, etc., as primary products, leaving coke as a residue, whereas in the case of the gas house, gas is the primary product, and although coke is again a residue, to a certain extent there is not the same temptation to extract the volatile oils to their utmost capacity as in the case of furnace coke. This directly affects the value of the coke for greenhouse heating.

The superiority of gas coke over raw coal for greenhouse boilers is incontestable, as gas coke contains no smoke-producing matter and requires less than half the amount of cold air necessary for raw coal for its complete combustion.

The art of successful stoking is to burn the fuel completely with as little air as practicable. Every pound of cold air in excess of that actually required tends seriously to cool the furnace, just as cold-feed water tends to cool the boiler. In theory, 1 lb. of coal requires 12 lbs. of air for its complete combustion, but in ordinary practice so much as 30 lbs. of air is frequently allowed in order to prevent emission of smoke. Heat absorbed in raising this excess air to the temperature of the chimney flue gases is wasted so far as the temperature in the greenhouse is concerned. It is obvious that under the low pressure principle of greenhouse boilers it is much easier to approach the ideal of complete combustion with coke than with coal as fuel, but the superiority of gas coke over furnace coke is not so generally appreciated. The latter is a harsh coke, not at all suitable for greenhouse boilers, and even when its B.T.U. content is equal to that of gas coke its efficiency is much lower because of the necessity of allowing an excessive amount of air to induce complete combustion.

Many gardeners who know these facts are not able to give their employers the benefit of the knowledge, but have to remain impotently in the background while the secretary, the agent or the housekeeper buys fuel judged solely on its paper price per ton, and with no regard to its real heating value or its suitability for the type of boiler concerned. *W. Auton.*

MARKET FRUIT GARDEN.

Although the rainfall of May (1·92 inch) was just above the average, it was the driest May we have had for four years. Most of the rain fell on the 5th, and towards the end of the month the land had become very dry, mainly as a result of several days of strong easterly winds. Although the weather was often cool, there was much sunshine. The Apple blossom, which began to open on the 10th, and was general on the 19th, encountered the best of the weather. Bees were very active and numerous, and conditions were altogether most suitable for pollenation. As a result, the bloom appears to be setting very freely, and there can be little doubt that a bountiful crop will be gathered. Nearly all varieties bloomed very profusely, some of them really too much. Three outstanding varieties are Worcester Pearmain, Bramley's Seedling and Lane's Prince Albert. Cox's Orange Pippin was very light on blocks of trees which have given me two heavy crops; but one lot which yielded less last year had plenty of bloom. Blenheim Pippin is also short with me, except for one row which failed last season. Beauty of Bath looks very promising, as do James Grieve, Early Victoria, Lord Grosvenor, Lord Derby, Newton Wonder, Allington Pippin, and Royal Jubilee. I do not know when I have seen so much bloom on Warner's King.

Plums evidently suffered more from frost than appeared at the time. In one plantation Victoria was practically wiped out and the bloom of Belle de Louvain severely thinned. In another plantation both escaped. Other varieties have reached the stage where a few of the fruitlets are swelling, but others lagging behind. The chances are that the latter are not going to hang, in which case the crop of Plums will be light. The most promising variety is Czar, which will almost certainly carry a full crop. Bush fruits all look exceedingly well, except in some low-lying spots where the bloom of Black Currants was caught by frost. Pears and dessert Cherries are not setting well, but these are of no commercial importance to me. Apples and Black Currants are my main crops, and should give me a good season.

Pests and Diseases.

Insect and fungus troubles are well under control so far. Winter moth and tortrix caterpillars were rather numerous on young trees, but have been killed by arsenate of lead. Plums and Black Currants in the immediate district are badly crippled by aphis; but in my plantations tar distillate wash has given a complete control. There are signs that the Currant capsid (Lygus pabulinus) is going to develop rather seriously; and this is really the only trouble in the way of insect pests. Apple-blossom weevil this year did a certain amount of unusual injury to the young leaves before the bloom opened, and has capped the usual percentage of blossom, a matter of no importance in a year when bloom is so plentiful. Apple scab I have not seen yet on any of my trees, with the exception of a Siberian Crab in my garden, which is always my scab barometer. As the first of the post-blooming sprays for scab prevention has been applied, there should now be no serious trouble from this disease. The weather when some of this spraying was done was such as to favour injury from lime-sulphur. Fortunately, very little occurred. There was a certain amount of leaf-drop in one batch of Cox's Orange Pippin from the use of lime-sulphur at only one part in a hundred, the strength which I was using for all varieties; so I diluted still further, to one part in 150, for other blocks of this variety, giving a good wetting instead of making any attempt at mere dewing over. This has done no harm at all, but may not be strong enough to do any good.

Response to Manuring.

Trees in my older grass orchards, both Apples and Plums, which have been treated under the "sod mulch" system for some years—the grass mown twice a year and allowed to rot into the ground—are showing a response to manuring which is quite spectacular. This is particularly pleasing to me, as I had nearly given up hope of reviving some of my trees without breaking up the turf. Last year, over a considerable area, they looked very poor indeed, showing marked symptoms of nitrogen starvation—small, light-coloured leaves, little growth, bark of a light colour, and a tendency to die back. This was in spite of a complete dressing of chemical fertilisers, including 3 cwts. per acre of nitrate of soda. This nitrate, which used to give me good results, appeared to be failing to act on the trees, even where the dressing was increased to 5 lb. per tree. Indeed, the effect hardly showed even on the grass.

Almost a chance experiment seems to have

Blonde or Brunette? A Complete Account of the Theory and Practice of Hair-Dyeing in all its Branches, by H. Stanley Redgrove, B.Sc., A.I.C., and Gilbert A. Foan. 8½ ins. × 5½ ins., pp. xii + 132 + 3 plates. London: William Heinemann (Medical Books), Ltd., 99, Great Russell Street, W.C. 1. Price 7/6 net.

given me a solution of the problem. I had some lime left over from spraying, and this was applied to the ground under some of the worst trees. Towards the end of the season I began to see some very slight improvement in these trees. The leaves were remaining green after those on the unlimed area had begun prematurely to take on autumn tints. An analysis of the leaves made at Long Ashton Research Station showed that those from the limed plot contained rather more nitrogen than the others. In some way the trees on the limed plot had been able to utilise some of the nitrogenous manure.

Now my soil is not short of lime, heavy applications of ground chalk having been made in previous years. I had tested the soil in all the plantations and found it neutral; and an analysis, also made at Long Ashton, confirmed this. Therefore the lime, if having any influence at all, must be working on the surface. As a matter of fact, it could not do anything else so soon after application on grass land, as the soil was very dry all the summer. It could only be supposed that it was working in some way on the mat of dead material which had accumulated as a result of the annual mowing of the grass. Apparently this mat was holding up the nitrogenous manure so that the trees could not get it; and the lime encouraged bacterial activity, resulting in the breakdown of the mat and the release of nitrates.

The same process occurs in the making of synthetic "farmyard manure" (as in the Adco process). All litter, such as cut grass or straw, is naturally covered with bacteria, which are waiting for conditions suitable for breaking it down. They can do this only in the presence of moisture, nitrogen, and some substance capable of neutralising acidity. In making "farmyard manure" from straw, sulphate of ammonia and ground chalk have been used successfully. Presumably, on the cut material in my plantations, the bacteria were present and the nitrogen had been supplied, but the bacteria could not get to work because of the absence of some neutralising agent. Where this was provided in the form of lime, bacterial action started and some of the nitrogen was made available to the trees.

Practical Application.

The theory seemed good enough to act upon. The possibility of making synthetic "farmyard manure" of the accumulated litter as it lay on the ground was attractive. Obviously, I must apply plenty of nitrogen and just a little lime or chalk to neutralise acidity. Calcium cyanamide and nitro-chalk immediately suggested themselves as suitable manures to provide both requirements. When synthetic manure is made in heaps, large quantities of water have to be used to saturate the litter. This being impossible on the ground in the plantations, rain must be depended upon. Therefore, I wanted some lime-nitrogen dressing of not too soluble nature which could be applied in autumn or early winter, when there would normally be plenty of rain following. I elected to use calcium cyanamide, and applied 3 cwts. per acre in December. As things turned out, my object was defeated by the weather, so little rain falling during the winter that the cyanamide remained dusty on the surface for weeks. I doubt, however, whether the idea of early application was sound, as the temperature would presumably be too low for bacterial activity until spring. It was later suggested to me that 3 cwts. of a rather slow-acting fertiliser like calcium cyanamide was rather light for trees in such poor condition on grass, so I added a dressing of 3 cwts. of nitro-chalk, applied in February, over the greater part of the area, making 6 cwts. of nitrogenous fertiliser per acre altogether. I can say at once, however, that parts of the plantations received the 3 cwts. of nitro-chalk only, and the result is just as marked at present as where the previous dressing of cyanamide was given; so I think the need for very early application can be ruled out. In future I should prefer to use nitro-chalk only, as the cyanamide burned the men who applied it, and probably the grass as well. Phosphates and potash were given in addition over the whole area.

The Result.

The effect of the manures showed from the beginning of the growing season. I have not had such foliage for years, if ever before. The leaves are big and of beautiful dark green colour. Old Plums, which seemed to be nearly worn out, appear likely to refurnish themselves with growth and take on a new lease of life, as they are pushing out new shoots from dormant buds along the main branches and stems. The grass, which was scorched brown by the combination of winter drought, frost, tar-distillate wash, and possibly cyanamide, was very late in making a start, but is now growing vigorously and showing the dark green colour which is expected to follow nitrogenous manuring. Both trees and grass on a plot which received phosphates and potash, but no nitrogenous manures, are in marked contrast to the rest of the area. Part of this plot was limed, to see whether lime without notrogen would answer, but so far this is giving a negative result. A plot from which potash has been omitted for two years is not yet giving definite results, except on the grass under the trees; but there may be a different story here as the season goes on. It is, however, rather soon to expect a response to the use of potash. Often this does not show until after the third or fourth application. Although my soil is very low in available potash, the need for it was not likely to be acute while the trees were in a definitely low nitrogen condition.

I have dealt with this matter at some length, because it may be of some use to growers who have trees in grass which are not responding to manures. In case some of my readers consider that I have written a lot of semi-scientific twaddle, I will sum up the situation in a very few words, as follows: In my conditions, fruit trees grown under the "sod mulch" system do not respond to nitrogenous fertilisers without the presence of a little lime. The new nitrogenous fertilisers with a lime base, such as nitro-chalk, therefore have a special value. On other soils, for all I know, the need for lime-nitrogen manures may not occur. A good response to nitrate of soda or sulphate of ammonia has often been reported. There may be something peculiar in my conditions, or it may be that, after years of sod mulch treatment on any soil, the accumulation of litter limits the effect of nitrogenous fertilisers which do not include lime. I ought to have found my solution sooner, because my records show that, in one season when I had a particularly good result from nitrate of soda, a dressing of ground chalk had been applied a few weeks before. *Market Grower.*

FRUIT GARDEN.

STRAWING STRAWBERRIES.

It is essential that Strawberries should be marketed in clean condition, otherwise they are quite worthless. The method of strawing which is usually adopted for this purpose is the most satisfactory, but the work must be done at the right time to give the best results.

It is a matter of importance that the work should be carried out sufficiently late in the season for the final hoeing to keep the plants reasonably clean until after the crop has been harvested. At the same time, it is advisable to place the straw in position before the fruit has grown to such a size and reached such weight that it is laying on the ground.

Once the fruit has lain on soil for any length of time, especially during wet weather, it will never become thoroughly clean again. It will lose, to some extent, its fresh appearance when ripe, with the result that its market value will be reduced. There is also a good deal more labour needed in placing the straw in position once the fruit is on the ground. Each bunch of fruits must be carefully lifted and the straw placed beneath it, and even then some injury will be done to the crop.

There is some difference of opinion among growers as to the best straw to use for Strawberries, whether this should be baled or loose. Baled straw has the advantage of being very easily moved from place to place; but it takes a good deal of pulling to pieces. Straw from the stack is easy to handle once it is in position on the field, but it is very bulky to move from place to place.

If Strawberries are grown beneath half-standard trees, there is not the slightest doubt that baled straw has the advantage. It is difficult to get a load of unbaled straw down the rows.

In the cost of baled straw and unbaled straw there is a difference per ton. The baled straw costs a good deal more than the other, but when the difference in carting and in the labour of getting the straw out is taken into consideration, the difference in the cost is not great.

Whether loose or baled straw is used it should be clean, that is, free from weeds; nothing more quickly gets a Strawberry plantation overrun with weeds than the use of straw which is full of weeds, the seeds of which will be sown on the ground, causing endless work with the hoes as they germinate and grow in their new positions.

The work of strawing should be carried out with the greatest care. The straw should be properly drawn our or "yelmed," as it is called, as if it were to be used for thatching.

Particular attention is needed when placing the straw in position, as unless care is exercised in this direction, a good deal of the fruit instead of resting on the straw will be covered by it. This very often happens with those who have had little experience of the work.

Another matter of importance is the amount of straw which is put down. It is just as easy to put the straw down too thickly as too thinly. There should be just sufficient placed between the rows to cover the ground well, but no more.

A plan which is practised by some growers is to place straw along each side of the Strawberry rows, but to leave the middle of the ground between the rows free from straw. This is false economy, as should there come a single heavy shower of rain during the picking season, the soil from the middle of the row will be splashed about in considerable quantity, and a good deal will get on to the ripe fruit and ruin it for market. *J. W. Morton.*

VEGETABLE GARDEN.

CELERY.

The young Celery plants intended for the main crop should now be planted out in well-prepared trenches in which a liberal supply of well-rotted farmyard manure has been incorporated. If the seedlings were pricked out in cold frames, they should now be strong and sturdy and hardened off ready for transference to the open.

Trenches one foot wide will suffice for single rows, and one foot nine inches for double rows, About a week before planting give the surface a dusting of old soot, and fork it in lightly, and also before planting tread the soil lightly and rake it level if the ground is not too wet. Place the plants about a foot apart and, if in double rows, plant alternately, as this system will give the individual plants more room. When each row is finished, give a thorough soaking of water, preferably that which has been exposed to the sun and air. If the weather proves hot and dry water should be given almost every day, as Celery is a moisture-loving subject and will never grow well if allowed to become dry at the roots. Frequent dampings overhead in the late afternoon with a rosed can will also be found very beneficial, and if the weather is dull and showery, take advantage of this to give a dusting of soot. This not only helps to prevent attacks by the Celery fly, but also acts as an efficient fertiliser. Where supplies of liquid manure can be obtained, this should be diluted with water and the plants given frequent soakings, taking care not to pour it into the hearts.

During the summer it is a good plan to mulch the surface of the trenches with half-decayed stable manure; the frequent waterings will wash the nutrients from this manure down to the roots, while the mulch will also keep the soil in the trenches moist, and thus ensure free growth.

Towards the beginning of September the plants should be ready for the first earthing up. The grower should go along each row and carefully remove all the side-growths and decayed foliage, and then tie up each plant with a piece of broad Raffia. As each row is finished, give it a final thorough soaking with water, taking care to keep the plants themselves as dry as possible. Before any soil is placed around them they should be well dusted with old soot to ward off attacks of slugs during the winter. The trenches should have been cut out four feet apart, and, if this was done, there should be plenty of soil in the ridges between each trench for earthing up. Mark a trench out two feet wide down the centre of each ridge, pushing the spade well down each side, and the soil taken from the first spit on each ridge will be sufficient for a first earthing, which should not be more than a third of the way up the Celery plants, otherwise some of the soil may get into the hearts and cause them to either rot or become deformed. There will then be a narrow ridge of firm soil each side of the row, about a foot wide, and this, of course, will support the soil when the Celery is earthed up for the second and third time.

The ties should be loosened as the earthing up proceeds. Too much soil placed around the plants at one time is injurious; it is much better to complete the work in three operations, and the soil, after the last earthing up, should be placed well up to the foliage, and sloped outwards so much as possible to shoot off heavy rain. The sides of the banks should be made firm with the spade, thus giving them a tidy appearance and also warding off superfluous moisture. Give a good dusting of soot when earthing up is completed, and if the effects of Celery fly should appear, pick off the affected foliage.

If very wet weather should prevail in the late autumn some means should be taken to prevent too much water running down into the hearts of the plants. Some growers place sheets of galvanised iron along the rows. A good covering of clean straw placed along thickly in the form of a ridge will also assist in this respect, and this will serve to protect the crop in severe weather. Of course, in mild, dry weather, the coverings should be removed so that the air may circulate about the plants, otherwise there will be great danger of them rotting off.

The above remarks apply to Celery for ordinary use, but to obtain exhibition plants there is no better method of blanching than by using narrow bands of stout, brown paper. Exhibition plants should be put out in shallow trenches of well-enriched soil, and kept well watered and syringed. Keep all side growths picked off and mulch the surface with some well-decayed manure, as advised for the ordinary crop. Celery takes about six weeks to blanch well, and about this length of time before it is wanted for exhibition some bands of brown paper about six inches wide should be placed around the bases of the "sticks," tying them with broad Raffia. Continue to place the bands of paper up the sticks as they grow, examining the plants each time for side growths and twisted sticks, which should be removed; the final bands should be in position two or three weeks before the crop is wanted, thus ensuring an even blanch right up to the foliage. Some broad Raffia should be tied loosely around the foliage, to prevent the wind breaking it. Grown thus, it is an easy matter to apply water and stimulants and the plants should be well sprayed on all bright afternoons. When wanted for exhibition, they should be carefully lifted with a spade and the roots trimmed off, after which they should be sponged several times with clean, soft water, until they are quite clean. Celery is very brittle, therefore keep the tops tied up during transit to prevent them breaking. Each head, when dry, should be wrapped in clean, white paper, and when staged, should be syringed to keep it fresh throughout the show. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

HOME CORRESPONDENCE.

The Destructive Ivy.—As opposed to Sir Martin Conway's indictment of Ivy on old castles which you appear to endorse (p. 355), the views of the late Colonel Morgan, an archaeologist well-known in south Wales, may be of interest. The conversation arose over his failure to induce Ivy to grow over an ugly patch of concrete supporting the lower decaying portion of wall of that part of Pennard Castle (in the Gower Peninsula) which remains in a fair state of preservation. He was indifferent to the presence, or absence, of Ivy on old buildings, and expressed the view that, were it not for the Ivy on the walls of Oystermouth Castle, Mumbles (recently taken over by the Swansea Parks Department), many of those walls would have collapsed long ago. His view was that the stems of the Ivy often bound loose stones and masonry together, and that, where the Ivy was killed, collapse soon followed. However, from the botanist's point of view it was fortunate that it refused to grow at Pennard, as it is on those walls that Draba aizoides is to be found (not Penrice, as stated in Bentham and Hooker's *Flora*), so Hedera Helix was very considerate for once. *Cecil E Marks, Educational Garden, Singleton Park, Swansea.*

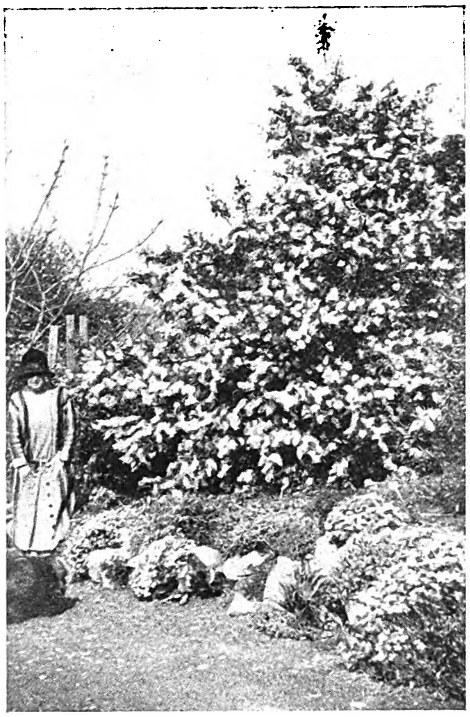

FIG. 229.—EXOCHORDA GRANDIFLORA AT KITTOES, BISHOP'S TEIGNTON.

Exochorda grandiflora.—In case it may interest your readers, I enclose a photograph (Fig. 229) of Exochorda grandiflora growing in south Devon. The plant has been in position for four years, and was about two feet high when planted. It has been a glorious sight. *Harry Geo. Younger, Kittoes, Bishop's Teignton, South Devon.*

The Iris Society's Show.—It was generally admitted that the Iris Show was a great success. It was run on somewhat novel lines, as the Executive Committee in March delegated to individual members of the Committee their particular functions and did not meet again until the day of the show. The plan worked admirably, and Mr. Pilkington, Mr. Barr, Major Churcher, and the other members of the Committee are to be congratulated. Most of all, however, I should like to mention Mr. Dillistone. Although in bad health—he had to go to a nursing home for a small operation on the evening of the first day of the show—his arrangements for housing the exhibits were perfect. The lay-out was very good, and it was achieved with the use of material placed at the disposal of the Iris Society by the R.H.S.; everyone will wish Mr. Dillistone a rapid recovery. The trade put up magnificent displays, all of which were in perfect taste; they allowed the flowers to speak for themselves, and I have never been to a show where the names of the firms exhibiting were less conspicuous; indeed, this proved somewhat of an embarrassment, as it was often difficult for visitors to find the display of a particular firm. The exhibition of pictures of Irises was a gratifying and instructive feature; the beautiful drawings made by the late Mr. Champion Jones for Miss Willmott were an object lesson, and Mr. Galsworthy's pictures of Irises actually deluded the public into thinking that they were living plants; while the rich colours by that grand old veteran, Mr. Caparne, gave a real sense of the decorative value of the plant. The competition for Irises arranged for decorative effect should be developed—two exhibits were exceedingly good. The stalls furnished by *The Gardeners' Chronicle*, *Amateur Gardening* and *Gardening Illustrated* were much appreciated. Mr. Bunyard's display of Iris diseases was of the greatest possible interest, and we all hope that he will find time to continue and develop the work and indicate the remedies for the diseases to which Irises are becoming increasingly susceptible. *William Lawrence, Burford.*

R.H.S. Examinations.—Mr. Alfred Hughes, with less than two years' experience as an apprentice in the Cheadle Royal Hospital Gardens under Mr. A. Falconer, has been placed first, Class 1, in the junior examination of the Royal Horticultural Society, which honour also carries with it the Society's Silver Medal, the highest award obtainable in this section. A former apprentice, Mr. Ross Young, was placed second in 1928, and this year has gained high honours in the Senior section. This record appears to be unique outside colleges and schools of horticulture, and speaks highly of the training these lads get in gardens which have become notable in the north of England. A former student of these gardens, Mr. T. H. Everett, also gained high honours in the Royal Horticultural Society's examination while employed under Mr. Falconer, and after a very successful period at the Royal Gardens, Kew, is now head gardener to a millionaire at Yonkers, New York, and is a frequent contributor to the pages of *The Gardeners' Chronicle.* Young men employed at the Cheadle Royal Hospital Gardens are able to gain experience in all branches of gardening, as shown by the excellent and varied exhibits shown from Cheadle at the leading horticultural exhibitions. *F. C.*

Rosa gigantea Flowering Out-of-doors.—When referring to the flowering of Rosa gigantea at Cambridge Botanic Gardens (see *Gard. Chron.*, Vol. LXXXV, p. 228), no mention was made of this species having been flowered outside in this country. A specimen here has been flowering since June 1. It is growing on a wall facing south and formed nine flower buds. Two years ago it developed six blooms. At Brent Eleigh Hall, Lavenham, Suffolk, a specimen flowered outside in an open border in 1912, and again profusely in 1915. In June, 1915, I sent foliage and a flower to the Editor of *The Gardeners' Chronicle.* Both sets of cuttings from which these plants were grown were sent to Mrs. Pearson, from Hoti Maidaan, India, by Colonel Campbell, an officer in the Corps of Guides. The colour of the flower is white when fully developed, although the bud has a lemon tint. A condition which encourages this Rose to bloom is partial starvation. It should be left unpruned. It will also be noticed that three of the years I have mentioned were preceded by a very hot summer, viz.: 1911, 1914 and 1928. Many gardeners who served in the Wessex Territorial Division in India, 1914-19, will have seen this species in bloom around the cooler hill stations. It is illustrated in *Gard. Chron.* of November 5, 1921, and a writer inquired if it had ever been tried out-of-door in the warmer parts of England. This Rose has withstood 25° of frost here with no other protection than the wall. *Charles Hodgson, Acton Place Gardens, Sudbury, Suffolk.*

SOCIETIES.

IRIS SOCIETY.

June 6 and 7.—This special flower Society filled the new Horticultural Hall, Westminster, with Irises of considerable beauty. In the centre of the hall there were many fascinating collections arranged by the chief trade growers, and these were a very attractive feature of the show. The classes for new seedling Irises contained a goodly number of really meritorious novelties, and the chief amateur classes were also responsible for many magnificent spikes of tall bearded Irises. The show was opened, well on time, by His Excellency the French Ambassador, after which there was a luncheon to distinguished guests. In the afternoon, the R.H.S., The English Speaking Union and the Iris Society entertained members of the Garden Club of America to tea. In the morning of the second day of the show, Mr. R. W. Wallace initiated a discussion on " Garden Irises," and, in the afternoon, Mr. Peter R. Barr lectured on " Iris Species for the Garden." There was a very good attendance ; nearly five thousand persons passed the turnstiles during the two days.

New Seedling Irises.

In the open sections there were twelve classes for new seedlings and, with one exception, they were for bearded Flag Irises of specified shades of colour. Certificates of Merit were awarded to the newer varieties, which showed a distinct advance in their respective classes, and certain selected varieties also received medal awards.

Certificates of Merit.

Yukon.—A stately spike of Mrs. H. Darwin type. The flowers were large and delicately flushed with very pale blue. Shown by Mr. G. L. Pilkington.

Jane Austin.—A tall spike of white flowers feathered with purple. There was less feathering on the falls than on the standards. Shown by Miss Insole.

Jurion.—A robust purple bicolor of Lord of June type. The standards were of slaty-blue colour and the falls were purple, lined with deeper colour. Shown by Mr. Frank Burton.

Trigo.—An exceptionally tall spike of very large flowers of Edward Michel type. The standards were of deep electric-blue colour, and the falls, which measured over four inches in length and three inches across, were of violet-purple colour, shading to blue. This handsome variety was also awarded a Silver Medal. Shown by Miss Insole.

Carfax.—In the same class as the foregoing variety the Silver-gilt Medal was awarded to a magnificent spike of exceptionally branching habit. The spike bore six fully open flowers and three buds. The standards were of electric red-purple colour and the falls were a deeper, velvety red-purple. Shown by Mr. A. J. Bliss.

Unnamed.—A tall spike of Alcazar type. The standards were of shot-purple colour and the falls were violet-crimson with deep veining. Shown by Mrs. Hamilton Rowans.

Unnamed.—A dwarfer spike of Eldorado type. The standards were yellow with a smoky centre and the falls were yellow, heavily veined with smoky-purple. This variety also received a Silver Medal. Shown by Mr. G. G. Whitelegg.

Joan Curtis.—This was probably the best garden variety among the new seedlings. It has a sturdy spike of flowers possessing exceptional substance (Fig. 219). The standards were of brilliant rich golden-yellow and the falls were reddish-maroon lined with yellow at the base. This variety also received a Silver Medal. Shown by Mr. Amos Perry.

Dog Rose.—A very tall spike of pallida type, with shining rosy-mauve flowers. Shown by Miss Insole.

Competitive Classes.

Many magnificent blooms, especially of bearded Irises, were to be seen in the competitive classes, and, generally, competition was keen. There were no finer blooms in the show than those exhibited by Mr. G. L. Pilkington, Liverpool, in the class confined to amateurs, for a group of bearded Flag Irises on an area of seventy-square feet, and with which he easily secured the first prize. It was a magnificent collection of extremely choice sorts, and included Bruno, in splendid condition ; Micheline Charraire, a grand white ; Souvenir de Letitia Michaud, lavender-blue ; Mary Gibson, pale smoky-plum, shaded gold ; Kenya, a good yellow, with pale cream falls ; Madame Cecile Bouscant, rich rose-lavender ; Louis Bel, small, rich velvety-purple ; Flaming Sword, Mrs. H. F. Bowles, Grey Lady, Nemoralia, a tall variety, with large, slaty-lavender blooms ; Coronago and Leonato. Mr. B. R. Long, Maidstone, was second, his best sorts being Mary Gibson, La Grand Ferré, Farrandale, Feronia, Amber, rich yellow ; Lady Charles Allom, deep purplish-blue, and Nemoralia ; while in his third prize exhibit, E. W. Meyerstein, Esq. (gr. Mr. Clapham), Morant's Court, Sevenoaks, included Lord of June, Catherine, Ann Page, Alcazar and Celestial in good condition.

In Class II, for a group on an area of thirty-six square feet, the Rev. Rollo Meyer, Watton Rectory, Herts., was first with a choice collection which included Dream, rose-coloured ; Balaruc, a good white of medium size ; Souvenir de Madame Gaudichau, flavescens, Kochii, and several good seedlings. Mr. G. P. Baker had grand vases of Sikh, smoky-plum-purple with velvety falls ; Moonlight, slaty-white ; Encorceleur, Alcazar, Clewen, and King Karl, with crinkled, apricot-tinted, biscuit-coloured standards and purple-spotted falls, in his exhibit, which was awarded the second prize ; while the best blooms in the third prize group, exhibited by Sir William Lawrence, Bart., Burford, Dorking, were of Titus, Diana, Lent. A. Williamson, Nemoralia, Opera and Aphrodite.

Mr. G. L. Pilkington was first with grand blooms in the class for a group of bearded Flag Irises on an area of twenty-four square feet, his best vases being of Lord of June, Quaker Lady, Africa and Mercedes. Mr. J. Sutcliffe Pyman, Sutton Scotney, was second, showing excellent examples of Medrano, Chasseur, Quaker Lady, Monsignor and Flaming Sword, while, in his third prize exhibit, the Rev. Rollo Meyer's best blooms were chiefly of unnamed seedlings.

Sir William Lawrence, Bart., was first in Class IV, for eighteen spikes of bearded Flag Irises, not fewer than nine varieties, his collection containing grand blooms of Ballerine, silvery-lavender standards and purplish-blue falls ; Allies, smoky-plum standards, with darker, velvety falls shaded brown at the base ; Glamour, Afterglow, with pale, slaty-lavender standards and slightly darker falls ; Lord of June and Blanche de Cashmère. Outstanding sorts in the second prize exhibit by Lady Elphinstone, Carberry Tower, Midlothian, were Albert Victor, violet-blue ; Opera, Thuban, large, lavender standards and purplish-blue falls ; Susan Bliss and Iris King. Third, Mr. J. Sutcliffe Pyman, who included good quality blooms of Medrano, Flaming Sword, Princess Beatrice and Monsignor.

For twelve spikes of bearded Irises, not fewer than six varieties, the Rev. Rollo Meyer was first, with Bruno, Amber, Duke of Bedford, Micheline Cherraire, Lord Lambourne, G. Parthuis and Leonata ; second, Mr. J. Sutcliffe Pyman, who showed very good blooms of Medrano, Flaming Sword, Ma Cherie and Ambassadeur.

Mrs. E. M. Garnett, Londonderry, led for six spikes, not fewer than three varieties, with grand examples of Grace Sturtevant, Gabriel Melchior and Mrs. Valerie West ; second, Rev. Rollo Meyer, with Amber, Duke of Bedford, Oriflamme and Crusader, very fine ; while Mrs. Garnett was also first for three spikes of any one variety, with Mrs. Valerie West ; second, Mr. J. Sutcliffe Pyman, who showed Princess Osra, a lovely sort, white, shaded and dotted lavender, especially on the margins.

In Class VIII, for three spikes of each of three different Irises, other than bearded sorts, Mr. M. G. Fitzhugh, Ashford, Kent, was first, and Miss L. Pesel, Twyford, second, the latter exhibitor being first in the next class, for six spikes of bearded Irises, not fewer than three varieties, open to amateurs who had never won a first prize at a previous show of the Society ; second, Mr. F. W. Hellizs, Kingston-on-the-Hill ; third, Mr. F. W. Tomalin, Hampton, Middlesex.

There were many fine vases in Class X, for three spikes of one variety, under the same conditions as for Class IX, Miss Pesel being first with grand blooms of Marjory Tinley, rich lavender; Mr. F. W. Tomalin, with Greven, and Mr. E. C. Levett, Kingston-on-the-Hill, shared the second place, the latter exhibitor showing Jacquiniana. Miss Pesel was also successful in Classes XI and XII for three varieties of white or cream bearded Irises and yellow bearded Irises respectively.

In the class for twelve spikes of American bearded Irises, Mr. G. L. Pilkington, Lower Lee, Woolton, Liverpool, was awarded the American Iris Society's Medal for a handsome exhibit which included exceptionally good spikes of Shasta, Bravira, Kathlyn Fryer and Morning Splendour. Miss L. Pesel, Church Farm, Twyford, Berks., was awarded the first prize for six spikes of American bearded Irises.

There were five exhibits of six vases of Iris sibirica varieties. Mr. G. Yeld, Gerrard's Cross, Bucks., was first with a beautiful collection which included I. sibirica var. alba and the varieties Papillon, Dragon Fly and Nora Distin. Mr. G. H. Furness, Somerset, was second. Mr. G. L. Pilkington, the only exhibitor, was awarded the first prize for six excellent vases of bulbous Irises.

The class for a collection of species and varieties filled a fair space. The first prize was awarded to Sir William Lawrence, Bart., Burford, Dorking, who included vases of I. graminea, I. setosa, I. tectorum, I. sibirica and a dusky hybrid from I. sambucina × I. paradox. Mr. H. Fitzhugh was second.

The Gordon-Lennox Challenge Trophy, which was offered for an exhibit to demonstrate the decorative value of Irises, induced an interesting competition. The Trophy and Silver-gilt Medal were awarded to The London Gardens for a novel exhibit of bowls and baskets of Irises. The receptacles, pedestals and staging were all of silvery colour. Mr. R. Silvester, who was awarded a Silver Medal, had a varied exhibit of considerable fascination, among which a large, low vase of Irises with plants of Carex and Selaginella found many admirers. Messrs. Robert Green, Ltd., were also awarded a Silver Medal for an attractive exhibit, and this included a hamper of Irises, a Victor wreath and a charming table centre. A Silver Medal was awarded to Miss L. Pesel for a table of Irises in bowls and vases.

Non-competitive Exhibits.

The trade responded admirably to the Iris Society's appeal for support in making this show a success, with the result that the main portion of the new hall was filled with many splendid collections of Irises, which made a grand display, the competitive classes being chiefly confined to the aisles.

Facing the main entrance were several large, rectangular, raised beds of Irises ; that set up by Mr. Amos Perry, who used Nepeta Mussinii and ornamental foliaged shrubs in association with his Irises, being very fine. In the centre of the group were grand blooms of Zillia, rich lavender, and Prosper Laugier, the group being made up of masses of the large-flowered, lavender-blue Duke of York ; Mrs. Marian Cran, purplish-rose ; Odessus, Olive Murrell, Olympus, Belladonna, rich blue ; Souvenir de Madame Gaudichau, royal purple ; Nemoralia, slaty-lavender ; Lady Charles Allom, Norman Bates, smoky-plum-coloured, lit with gold, and many others. Clorinda, Yellow Moon, No. 1,851 and No. 1,857, were good yellow sorts ; others of outstanding quality in this collection being No.

802, with plum-purple standards and deep velvety-purple falls, the whole shaded from the centre with gold; No. 0,669, Mary Gibson, Tangerine, very richly coloured, and the giant-flowered Niagara.

Messrs. R. Wallace and Co., Ltd., also had a grand collection, which embraced many fine varieties, was arranged tastefully, and included several good seedlings. There were lovely blooms of Mrs. Marian Cran, the cream-coloured Ivory; Sir Galahad, purple; Majestic, Julia Marlowe, light purple, with darker falls; Evadne, Pioneer and Bruno, while among the unnamed seedlings of note were 160/2, with smoky-lavender standards and purple falls; 4/1, bright, rich blue; 1/15, lavender-blue standards and purple falls; 160/1, smoky, pale purple standards, with deeper velvety falls; and 18/16, a good bluish-purple sort.

Mr. George G. Whitelegg had a choice group which included the beautifully coloured Ambassadeur; Souvenir de Madame Gaudichau, Prospero, Mrs. Frank Tiark, the small-flowered, bright reddish-purplish Opera; Mrs. George G. Whitelegg, the exquisite Citronella, with clear, bright yellow standards and red-shaded and veined falls; and the popular and valuable Alcazar.

Messrs. Lowe and Gibson, Ltd., had good vases of Eldorado, Romany, the pink Rhoda, Quaker Lady, Iris King and Mary Gibson, together with several very choice seedlings; while Mr. Gavin Jones, in his massed group, included Alcazar, Ma Mie, Ambigu, Maori King, Prosper Laugier, Dawn and I. pallida var. Empress of India.

The circular, open space in the centre of the hall was bounded by four triangular beds, set up by Messrs. George Bunyard and Co., and the Orpington Nurseries Co., Ltd., respectively. The two beds arranged by the former firm would have been improved considerably had some attempt at "finishing' the exhibit been made; as it was, the baskets and vases, and the Iris roots wrapped in sacking, detracted somewhat from the otherwise bright effect of many really good blooms. Among tall sorts which formed the centre of these triangles were Yeoman, dalmatica, Yolande, rich, deep blue with purple falls, very fine; Mdlle. Schwarz, pale lavender; Morning Splendour, Mrs. H F. Bowles, Crusader, bright, rich blue; Souvenir de Letitia Michaud and the richly coloured Sirius; while of the choice sorts bordering the groups, the most striking were Iris King, Nene, very fine; Romany, Troost, Pioneer, rich purple; Magnifica, very large; Loreley, Mira, of very delicate shading; Billia, Shekinah, yellow; Eldorado, Fro and Ed. Michel, purplish-red.

From the Orpington Nurseries Co., Ltd., came many large baskets and boxes of good blooms, but here, again, the receptacles were very much in evidence. Souvenir de Madame Gaudichau, Gabriel, Mdlle. Schwarz, Lord of June, Shekinah and Aphrodite were shown in large clusters, while among the choicest sorts were the golden yellow Rialgar; rich blue Wedgwood; White Queen, Rosalba, Romola, Deuil de Valerie Mayet, very beautiful; Evadne, Romance, Fra Angelico, of uncommon shading; Diogenes, Grace Sturtevant, Seminole, Tenebrae and Majestic..

Messrs. Barr and Sons had a magnificent rectangular bank of blooms, crowned with sheaves of Queen Mary, Cottage Maid, Minnehaha, Viola, Mount Penn and Souvenir de Madame Gaudichau; other good sorts in this excellently arranged display being Magnifica, Ringdove, Quaker Lady, Lohengrin, Hon. Mrs. Kingcote, Lent A. Williamson, Wyndham, Lac Leman, Moliere, Troost, Mrs. H. Darwin and Mons. Aymard.

Messrs. Waterer, Sons and Crisp also provided a very attractive and tastefully arranged display, among their best sorts being Ballerine, Magnifica, Moliere, Vesuvius, Isolene, Ed. Michel, variegata aurea, Ilsan, the richly shaded Mons. Brun, Fryer's Glory, Eurydice, very fine; Flaming Sword, Oriflame, Deuil de Valerie Mayet, Lohengrin, Lord of June and Fro.

In the collection of choice sorts set up by Mrs. W. R. Dykes we noted, as outstanding, the beautiful, yellow Amber; Wedgwood, the slaty-white Moonlight; Drancos, a giant, purple-flowered sort; Iceberg, Cupavo, rose-purple; Molo, Priestess, Gilda, another yellow sort; Harmony, Peerless and Thrill, all very striking.

Mr. G. Reuthe had a mixed collection of bearded Irises, while Messrs. Daniels Bros. included good blooms of Mrs. Allan Gray, Asiatica, Mount Penn, Prosper Laugier and Walhalla, in their small group.

The Horticultural Department of the University of Reading was responsible for an interesting exhibit demonstrating the colour classification of the bearded Irises, while from the Royal Horticultural Society's Gardens at Wisley came a collection of old Iris varieties, taken from the standard Iris collection, and demonstrating very emphatically the remarkable advance made in the production of varieties of bearded Irises during recent years.

Another exhibit of high educational value was that set up by Mr. G. N. Bunyard, who has been making a special study of the diseases of the Iris for some time, and although his work is not yet nearly completed, he has already made some important discoveries. His exhibit, besides demonstrating the more familiar diseases of the Iris, such as Iris rust and Iris leaf-spot, and the damage done to foliage by frost, which might well be mistaken for fungus attack at a glance, also included two distinct types of rhizome soft-rot, which is responsible for considerable havoc among Iris plants. Mr. Bunyard has come to the conclusion, and it would appear to be a very important one, for, if true, it will upset all previous conception, that the soft-rot (No. 1), which is generally considered due to bacterial agency, is caused by some other agency, at present unknown, for after repeated attempts at inoculation of Irises with this bacteria, Mr. Bunyard has failed to produce rhizome-rot, which would suggest that the bacteria is not primarily responsible for this disease. The second type of soft-rot, however, is definitely caused by a Botrytis, and Mr. Bunyard staged a series of illustrations demonstrating the Botrytis organisms in the Iris tissues. But the most important trouble, which is likely to become a serious menace to Irises in this country, is what is known as "scorch" or "fire." Whether this is due to the presence of fungus or bacterial organisms, or is merely physiological, has not yet been determined, but Mr. Bunyard has carried out preliminary investigations, and work on it is also being carried out in other quarters. Soil conditions, in the matter of acidity, etc., would appear to have no influence, for the trouble which commences with the withering of the roots, followed by their death, and results in the browning and dying of the foliage (the specimens demonstrated only too well the state to which healthy Iris plants are reduced to by it) has been located at various places in this country, and in a variety of soils. So far, Mr. Bunyard has discovered three distinct fungi in affected plants, but it is too early yet to state how far any of these may be responsible for the trouble.

There were several very attractive exhibits of paintings of Irises. Mr. Frank Galsworthy, Chertsey, showed beautifully executed paintings of many varieties and species; the Royal Horticultural Society exhibited the late Mr. W. R. Dykes' original paintings of Irises; while Miss Ellen Willmott showed a grand series of Irises grown at Warley, painted by Mr. Champion Jones. An extensive series of Iris paintings was also exhibited by Mr. Caparne.

Horticultural Journals were also well represented, *The Gardeners' Chronicle* staging a collection of coloured plates and books, including some specially devoted to Irises; while *Gardening Illustrated* and *Amateur Gardening*, also had interesting exhibits of books, etc.

THREE COUNTIES' AGRICULTURAL.

The Three Counties' Agricultural Society is to be congratulated on the horticultural features in the great show held at Gloucester on June 5, 6 and 7, and it is true to state that nothing in this show ground attracted more attention and praise than the exhibits in the flower tent. The arrangements for this section were in the hands of Mr. S. Starr, the Secretary of the Gloucestershire Root, Fruit and Grain Society, and he was admirably supported by the exhibitors, all of whom represented the trade.

A charming feature at the main entrance was a formal garden of an old-world character placed there by Messrs. Hopwood and Sons, in which grey stone was used with good effect and gave the garden a typically Cotswold appearance. The same firm also set up a formal garden at the end of the tent, which was of very attractive appearance.

Sweet Peas were a great feature and the display set up by Messrs. Dobbie and Co. was much admired, particularly the big masses of Clarion, Mrs. A. Searles, Flamingo and Pinkie. Another exhibitor of Sweet Peas was Mr. J. Stevenson, who showed good flowers of a choice selection of varieties.

The Carnations shown by Mr. C. Engelmann were worthy of the reputation of this famous grower, and the splendid flowers exhibited called for many expressions of praise. Messrs. Allwood Bros. also sent a fine lot of Carnations, which included all the best-known varieties, both for indoor and outdoor cultivation.

There was a reminder of Chelsea in the fine display of Delphiniums of named varieties, and wonderful flowers of Begonias, staged by Messrs. Blackmore and Langdon, and this exhibit was much admired. Mr. A. Hurren set up a simple but extremely pretty paved garden flanked with flowering plants set out in beds and borders. Messrs. J. Kelway and Son filled a large space with an interesting collection of Pyrethrums, Delphiniums, Paeonies and Gladioli, which were all greatly admired.

A very interesting display of hardy flowers, many of them rare, came from the Colesborne Gardens (Mr. W. H. Walters) and attracted a good deal of attention. The collection of Polyantha and other Roses from the Madresfield Gardens, Ltd., which occupied one side of the tent, was very pleasing, the plants being well flowered and of very healthy appearance. Not the least interesting exhibit was a collection of Aquilegias, set up by Mr. Charles Wall, and near to it was a formal Iris garden arranged by Messrs. Bowell and Skarratt.

Messrs. J. Peed and Son arranged a nice group in which Hydrangeas, Caladiums and Liliums were conspicuous. A fine lot of Delphiniums was shown by Messrs. Hewitts, and Messrs Rich set up a miscellaneous collection of flowers. Messrs. Bakers made a grand show with Pyrethrums, Delphiniums and Larkspurs in great variety, and the rock garden on a table, arranged by Messrs. Maxwell and Beale, again reminded one of Chelsea.

Single Dahlias came from Mr. Thomas Robinson, while Messrs. J. Cypher and Son filled an end of the tent with a mixed group of fine plants. Messrs. B. Cant and Sons sent a beautiful lot of Roses, among which rambler varieties were conspicuous. Lupins and Irises staged by Messrs. Jarman and Co., were good. Messrs. Toogood set up a bank of Schizanthuses and Cinerarias, with some well-flowered Stocks in pots.

An extremely interesting collection of hardy flowers was shown by Messrs. J. Jefferies and Son, and a big display of Dahlias came from the King's Acre Nursery, who also set up a fine group of Hydrangeas. There were other attractive features, and it was generally agreed that the show was the best of the series organised by the Three Counties' Society.

DERBYSHIRE HORTICULTURAL.

A Party of over sixty members of the Derbyshire Horticultural Association recently visited Foremarke Hall and Gardens by kind permission of Sir Francis Burdett.

Mr. Baldwin, the gardener, met the visitors and conducted them round the grounds which are laid amid a scene that is extremely picturesque at this period of the year, abounding in rich woodlands, beautiful specimen trees and well-kept lawns.

Rose gardens and Lily ponds, surrounded by well-clipped Yews, gave added charm and surprise views, while the flowering shrubs and Primula japonica in many colours adjacent to the rock and water garden were full of beauty.

Foremarke Church (St. Saviour) in the grounds also claimed attention. Built in 1662 and consecrated by Bishop Hackett, the sundials on the exterior (one of which is dated 1650) and an old three-decker pulpit, told of ancient glory.

Peaches, Nectarines, Figs, etc., were accommodated in the glasshouses, all giving good promise of healthy crops.

ROYAL HORTICULTURAL.

June 11 and 12.—As often happens at the meeting following the Chelsea show, the R.H.S. Hall was filled with excellent exhibits of a pleasantly varied character. Orchids of good quality were freely shown and the Committee recommended one Award of Merit to a novelty. The stove and greenhouse plants included especially good Hydrangeas, Gloxinias and Primulas, and there were many collections of hardy border flowers, particularly of Irises, Pyrethrums and Paeonies. The Floral Committee recommended twelve Awards of Merit. Beyond a good exhibit of Tomatos in pots, the Fruit and Vegetable Committee had nothing to occupy its attention.

Orchid Committee.

Present : Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Prince Shimadzu, Colonel Stephenson Clarke, Mr. Lionel de Rothschild, Mr. Frederick J. Hanbury, Mr. Stuart H. Low, Mr. R. Ashton, Mr. Charles H. Curtis, Mr. H. G. Alexander, Mr. S. Flory, Mr. Robert Paterson, Mr. H. H. Smith, Mr. J. E. Shill, Mr. Fred K. Sander, Mr. T. Armstrong, Mr. J. Cowan and Mr. A. A. McBean.

Although this Committee had no fewer than nine novelties before it, only one Award of Merit was granted and one Preliminary Commendation.

Award of Merit.

Laelio-Cattleya Hassallii var. alba, Arddarroch var.(Laelia Britannia var. alba × Cattleya gigas).—A very beautiful form, with ample white sepals and petals of fine substance. Lip very large, Tyrian-purple. Shown by Mrs. Brooman White, Arddarroch, Garelochhead.

Preliminary Commendation.

Miltonia Vida, Paterson's variety (M. Bleuana var. Reine Elizabeth × M. William Pitt).—A bright and attractive hybrid carrying two flowers on a quite small plant. The sepals and petals are crimson-purple ; lip of similar colour but softer hue, shading to rose-purple near the white margin. The radiating lines of the brown mask are edged with white. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Groups.

A fine feature of the group set up by Messrs. Charlesworth and Co. was a specimen of Coelogyne burfordiense, with three long spikes of its green and dark brown flowers. Miltonias and Odontoglossums, however, made up the bulk of the display, the former including M. Charlesworthii, M. gattonensis, M. Lydia, M. Lena, M. Wm. Pitt and M. Princess Mary. A novelty for these days was Laelia tenebrosa, while Dendrobium acuminatum, Phaius Norman, Oncidium anchiferum, Renanthera Imschootiana and Bulbophyllum Lobbii added interest to the beauty of the Odontoglossums, Laelio-Cattleyas and Odontiodas.

A handsome group was arranged by S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton. Vanda teres, V. coerulea, Thunia Marshalliana, Brassia verrucosa and Epidendrum prismatocarpum formed a background for fine spikes of Phalaenopsis Rimestadiana, Dendrobium acuminatum with seven spikes, D. Victoriae-Reginae, Zygopetalum citrinum, Cattleya citrina, the old and now apparently rare Peristeria elata, Lycaste locusta, L. costata, Cypripedium Parishii, with eleven flowers, Miltonias and Odontoglossums in variety, and Epidendrum pentotis with seven spikes, for which a Cultural Commendation was awarded.

A lovely lot of Miltonias from Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, attracted a great deal of attention, and won great admiration. Particularly fine were the examples of M. Lycaena var. gigantea, M. vexillaria var. Snowflake, M. gattonensis, M. Nellie Smith, M. Hyeana, M. Nadia, M. Bleuana, M. Mona, M. Wm. Pitt, M. Charlesworthii and the handsome M. Lucia, Paterson's variety.

Messrs. Stuart Low and Co. showed a small group which contained Laelio-Cattleya G. S. Ball, L.-C. Stevenson, L.-C. Aphrodite, Dendrobium Falconeri, Odontoglossum Williamsii, Miltonias, Masdevallias and Odontiodas.

Messrs. Sanders had a pretty exhibit wherein the long-spiked Oncidium Wentworthianum figured as a centrepiece. Around this were grouped Miltonias in great variety, Thunia Veitchiana, Dendrobium infundibulum, Cattleya Dupréana, C. Eve, a white hybrid between C. Undine and C. Lady Veitch, Odontioda Coronation, Stanhopea grandiflora with two flowers, Aerides Fieldingii, Lycaste cruenta var. majus, and Odontoglossum cordatum.

Baron Bruno Schröder (gr. Mr. G. E. Shill), Dell Park, Englefield Green, showed a lovely Miltonia named Snowflake, with white flowers, tinged with mauve at the bases of the petals, and a deep dark red-brown mask on the lip ; and M. William Pitt, Dell Park var., with three brilliant flowers.

Floral Committee.

Section A.—*Present :*—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mrs. Ethel Wightman, Mr. C. F. Langdon, Mr. N. Champion Haskett, Mr. A. E. Vasey, Mr. Donald Allan, Mr. D. B. Crane, Mr. J. M. Bridgeford, Mr. W. B. Gingell, Mr. R. Findlay, Mr. D. Ingamells, Mrs. Helen Lindsay Smith, Mr. J. T. West, Mr. G. W. Leak, Mr. W. Howe, Mr. E. R. Janes, Mr. Courtney Page and Mr. W. D. Cartwright, Secretary.

Section B.—*Present :* Mr. Charles T. Musgrave (in the chair), Mr. W. J. Bean, Mr. James Hudson, Mr. F. G. Preston, Mr. T. W. Taylor, Mr. A. Bedford, Mr. James Comber, Mr. W. B. Cranfield, Mr. Clarence Elliott, Lady Beatrix Stanley, Mr. G. Reuthe, Mr. Mark Fenwick, Mr. R. W. Wallace, Hon. H. D. McLaren, Mr. E. R. Wilding, Mr. L. R. Russell, Mr. George Yeld, Mr. T. Hay, Mr. Reginald Cory Mr. E. A. Bowles and Mr. N. K. Gould, Secretary.

Awards of Merit.

Carnation Flambeau.—A border variety of fine form with flowers on stiff stems. The colour is rich soft reddish-orange, the deepest shade being at the edges of the wide petals. Very faintly scented. Shown by Mr. James Douglas.

Grammatocarpus volubilis (syn. Scyphanthus elegans).—A slender, twining, hardy annual plant with elegant, much divided leaves and long-petioled flowers. The latter suggest both a Tropaeolum and a Columbine. They are rounded, clear yellow, with prominent brown anthers. The petals are bluntly spurred, and between these spurs a curious horned scale is bent at an angle like another spur. Calyx segments linear and deep green. Figured in *Bot. Mag.*, t. 5,028. Collected by Mr. Clarence Elliott during his Chile-Andean expedition. Shown by Major S. F. Harrison (gr. Mr. A. S. Hartless), King's Walden Bury, Hitchin.

Pentstemon procerus.—This name was given subject to verification. P. procerus is figured in *Bot. Mag.*, t. 2,954, but while the flowers are similar, the habit of the plant illustrated is different from that of the one exhibited. The stout growths remind one of the Soapwort, but they terminate in spikes of soft blue, mauve-tinted flowers. The spikes range from ten inches to nearly eighteen inches in length. Exhibited as a hardy plant. Shown by Sir William Lawrence, Burford, Surrey.

Heliophila linearifolia.—A charming, half-hardy South African annual of slender, elegant habit. The leaves are narrowly linear, about three inches long. The stems are slender and wiry, bearing branching spikes of round, white-eyed, blue flowers that are daintily beautiful, the blue being slightly deeper at the base of each of the four petals than on the limb. The plant will evidently need support because of its slender habit. Shown by Mr. T. Hay, Hyde Park.

Cynoglossum cashmerianum.—A plant that combines the elegance of a Forget-me-not with the sturdiness of a Borage. The rich green leaves clasp the stem and are soft to the touch. The flowers, about half-an-inch across, are deep blue and borne in branching cymes at the ends of the growths. Shown by Messrs. B. Ladhams, Ltd.

Lewisia pygmaea.—A charming little dwarf member of this popular genus, from British Columbia, and one of the choicest rock garden plants. It forms a close clump of rosettes of strap-like, grey-green, smooth and fleshy leaves, tinged with red down the centres, and produces very freely, on branched stems two inches high, white flowers about one inch across when expanded, flushed and veined with light reddish-purple ; their beauty is further enhanced by the crimson calyces, which are distinctly toothed. This choice alpine was shown by The Director, R.H.S. Gardens, Wisley.

Stapelia nobilis.—A plant of this Succulent, carrying one huge flower—quaint, but with no pretentions to attractiveness—was shown. It has erect, fleshy, four-angled growths six inches or so in height, the star-shaped flower, about nine inches across, having five large lobes spreading outwards from a central cavity and tapering at the apex. The flower is of a pale biscuit colour, heavily veined with horizontal, purplish markings, the margins being purple-marked, and the whole covered with hairs of similar colouring. Shown by E. M. Preston, Esq. (gr. Mr. G. F. Wood), The Warren, Hayes, Kent.

Chiliotrichum rosmarinifolium.—This interesting Chilean shrub, a member of the Natural Order Compositae, has narrow, dark green and glossy leaves, packed closely on the younger growths, its pure white, narrow-petalled flowers—like small Marguerites—being borne profusely at the ends of the previous season's growths, on stems three inches in length. Shown by Sir William Lawrence, Bart., Burford.

Pentstemon utahensis.—A tall-growing species producing pairs of short-stemmed clusters of striking, azure-blue flowers, mauve-coloured in bud, from the axils of large, rich green, leaf-like and heavily toothed bracts, at intervals along the stout, hairy, red-tinted stems. Shown by Mr. T. Hay, Hyde Park.

Calceolaria biflora.—This Calceolaria appears to us to be identical to C. plantaginea, figured in the *Botanical Magazine* (t. 2,805). It is not unattractive in appearance, and is of compact habit, forming a close mass of rather ample, broad, dark green foliage, from among which arise red-tinted, slender, hairy stems to a height of about one foot, usually bearing two large, rounded-pouched, rich yellow flowers. It is doubtful whether this Calceolaria, from Chile, will prove hardy, but it should prove a useful addition to the list of summer-flowering subjects for the rock garden. Shown by Lieut.-Col. L. C. R. Messel, O.B.E. (gr. Mr. J. Comber), Nymans.

Calceolaria Benthami.—This is an extremely charming herbaceous Calceolaria of dwarf, compact habit and, judging by the specimen shown, very free-flowering, for it produces a mass of slender, branching stems up to about ten inches high, and these are laden with small, rounded, golden-yellow flowers. The small, slender-ovate, grey-green, hairy leaves form a close clump. It would appear to be a good perennial. Shown by Lieut.-Col. L. C. R. Messel.

Lathyrus magellanicus.—This beautiful "Everlasting" Pea has handsome spikes of flowers, five or more in number, and carried on strong, erect stems. The flowers have rich, rose-purple wings and paler keels, which, however, vary somewhat in depth of colouring. Also shown by Lieut.-Col. L. C. R. Messel.

For Trial at Wisley.

Lupinus polyphyllus var. Duke of Richmond.—A very handsome spike of deep rose-coloured flowers.

L. p. var. Reason.—A pretty bicolor variety. The keel is pale pink and the standard is a deeper shade of the same colour. This and the above were shown by Mr. J. A. Downer.

L. p. var. Grace Fanwell.—An uncommon and attractive bicolor variety. The keel is coloured pale buff, and the standard is a dull terra-cotta. Shown by Messrs. M. Prichard and Sons.

Iris T. W. Thornton.—A tall bearded Flag Iris. The flowers were large and a trifle congested. The standards are pale blue, and the falls a slightly deeper blue. Shown by Mr. F. Bostock.

Pyrethrum Red Emperor.—A robust, single-flowered variety. The ray florets are broad, stiff, and of velvety-crimson colour. Shown by Mr. Herbert Robinson.

Salvia Simmonsii.—A very dwarf and free-flowering variety of Pride of Zurich type. The flowers are of dazzling scarlet colour. Shown by Mr. H. Simmons.

Groups.

Immediately inside the hall a magnificent group of Hydrangeas was exhibited by Baron Bruno Schröder (gr. Mr. E. J. Henderson), The Dell Park, Englefield Green. The plants all displayed superb cultivation and the group was arranged with great skill. The chief varieties were Rubis, Le Marne, Madame Moulliere and Madame Chautard, which bore immense, shapely trusses. In the centre there was a graceful Kentia Belmoreana, surrounded by the brilliant Hydrangea Parsifal, and well-grown specimens of various Dracaenas added to the beauty of the group. In another part of the hall, Messrs. H. B. May and Sons had an attractive group of Hydrangeas.

At the far end of the hall, the centre position was filled with a very charming group arranged by Messrs. Sutton and Sons. This contained circles of splendid Gloxinias and Primula obconica set in a mossy ground in which were placed Ferns and small plants of various Codiaeums (Crotons) and Cocos Weddelliana. The Primulas were especially floriferous and in batches of distinct colour varieties, such as Salmon Queen, Salmon King, Giant Crimson and Giant Pink.

The walls at the Elverton Street exit were particularly attractive with magnificent massed Zinnias backed by Clerodendron fallax, arranged by Messrs. Sutton and Sons. An interesting collection of miscellaneous greenhouse plants, arranged by Messrs. Stuart Low and Co., included Metrosideros floribunda, Boronia elatior, Hedychium Gardnerianum and various Ericas.

Carnations were well shown. Mr. James Douglas had an especially good collection of his border varieties. The novelties included Fancy Free, a good Fancy which has bright scarlet lines on a pink ground, and Hobby Elliott, a white-ground Fancy, freely marked with rosy-purple. Calypso is chiefly of smoky heliotrope colouring with a citron base and occasionally flushed with rosy-pink. Among the older varieties were Sunflower, Edenside Beauty and Swarthy Clove, of delicious fragrance. Their customary collections of good greenhouse Carnations were staged by Messrs. C. Engelmann, Ltd., Messrs. Allwood Bros., and Messrs. Stuart Low and Co.

At the far end of the hall, Messrs. Dobbie and Co. set up an extensive collection of excellent Sweet Peas. Their novelties included Clarion, rosy-purple, and Blue Flame, an uncommon bicolor. They also had charming bowls of Royal Sovereign, Flamingo, Magnet, Mrs. A. Searles, Idyl and Gleneagles.

Pyrethrums were particularly well shown. In their collection, Messrs. Kelway and Son included such good singles as Eileen Kelway, soft pink; Eileen May Robinson, medium pink; and Mrs. Bateman Brown, deep rose; while among the doubles were Lord Rosebery, crimson, and Virgo, creamy-yellow. They also showed Paeonies and Gladioli. Messrs. Barr and Sons showed many good Pyrethrums with Irises, Lupins and Heucheras. Miscellaneous border flowers were staged by Messrs. Wilson and Agar, Mr. Stephen Sims, Messrs. W. H. Rogers and Son, Messrs. E. J. Redgrove and Son, Mr. George E. P. Wood, Mr. Gavin Jones, Messrs. B. Ladhams, Ltd., and the Suffolk Seed Stores.

Collections of desirable Lupins were arranged by Mr. G. R. Downer, and Messrs. Prichard and Sons. Messrs. Tuckers, Ltd., had a good selection of alpines; Messrs. Maxwell and Beale included the yellow Gazania Vanity and Primulas in their rock garden. Mr. J. Robinson had good breadths of Cheddar and other Pinks. Messrs. Solihull set up tall spikes of Delphiniums with Lupins; and the Rolvenden Nurseries grouped a large quantity of Statice profusa var. superba.

A brilliant group of Rhododendrons was exhibited by Messrs. Waterer, Sons and Crisp. The pink varieties were especially prominent and these included Prince of Wales, Philip Waterer, and a good, deep pink raised from R. discolor and a hardy hybrid. Messrs. Patricks grouped deciduous Azaleas with Kalmias, Brooms and Philadelphuses. Mr. J. H. Pemberton included well-flowered sprays of Austrian Yellow and R. Sinica var. Anemone in a collection of Roses.

There were several charming exhibits of bearded Irises at this show, the mound of blooms arranged by Messrs. Waterer, Sons and Crisp, Ltd., with various brightly coloured Pyrethrums at each end, being very fine. The central group of Ambassadeur was outstanding, other prominent sorts including Asia, Rhein Traube, Isoline, Corrida, John Waterer, Prospero and Shikinah.

Mr. George G. Whitelegg had a small collection of choice sorts, such as Eldorado, Honorbile, Ballerine, Asia, Ambassadeur, Goldcrest, Lord of June, Alcazar, Mrs. Valerie West, and several good seedlings under numbers, while Messrs. R. Wallace and Co., Ltd., showed many grand Irises in conjunction with Eremuri, Lupins and Liliums, including L. regale. L. pyrenaicum, L. Brownii and L. elegans var. Mahogany. Among their Irises, Lady Foster × Bruno, Susan Bliss × Roseway, flavescens alba, Mesa, Pioneer, Lent A. Williamson, Florence Wells, Souvenir de Madame Gaudichau, Stamboul and Melchior were noteworthy, but their grandest blooms were of unnamed seedlings.

Messrs. George Bunyard and Co., Ltd., showed excellent blooms of Souvenir de Letitia Michaud, Corrida, Loreley, Glitter, Ballerine, Ambassadeur, Alhena, Izar, Phieda, Dusky Maid, Vannessa and Iris orientalis var. Snow Queen, in their attractive collection; while among the many grand sorts exhibited by the Orpington Nurseries Co., Ltd., the most noteworthy were Edouard Michel, Afterglow, Romance, Titan, Evadne, very bright; Souvenir de Madame Gaudichau, Shikinah, Neptune, Lord of June, Romola, Mother of Pearl, Fro, Brilliant, Sir Michael and Wedgwood, to mention but a few.

Fruit and Vegetable Committee.

Present: Mr. W. Poupart (in the chair), Mr. W. H. Divers, Mr. A. Bullock, Mr. H. Markham, Mr. E. A. Laxton, Mr. P. H. Tucker, Mr. A. Poupart, Mr. F. Bostock, Mr. E. Beckett, and Mr. A. N. Rawes, Secretary.

This Committee had no business of importance to conduct.

Groups.

Messrs. S. Bide and Sons showed about a dozen fully-grown plants of their new Tomato Bide's N.C.O., a heavy cropper, judging by the giant trusses of excellent fruits each plant was carrying.

The Ministry of Agriculture had an exhibit of Tomatos and Cucumbers packed and graded as required under the National Mark scheme, which proved very instructive to commercial growers of these commodities.

Obituary.

Robert John Harvey-Gibson.—The announcement of this eminent Scottish botanist's death was received with extreme regret in Aberdeen University circles. The son of the late Rev. Robert Gibson, a minister of the Scottish Episcopal Church, Professor Harvey-Gibson spent his boyhood days at Cuminestown, Aberdeenshire, where his father was priest in charge. From thence he proceeded to the Aberdeen Grammar School, where he won the Drum Presentation Bursary of £40. There he made capital progress, and in due course entered Aberdeen University, where he graduated in 1880, and has proved one of his Alma Mater's most distinguished sons. He also passed through the Universities of Edinburgh and Strassburg, where he showed eminent ability for his lifework as a botanist. Dr. Harvey-Gibson's first public appointment was as demonstrator of zoology in Edinburgh University in 1882, and the following year as demonstrator of physiology at the same university. In 1885, Professor Harvey-Gibson entered upon his lifework at University College, Liverpool, where, in turn, he was demonstrator of biology and lecturer in botany. In 1891 he was appointed to the Chair of Botany at the University of Liverpool, becoming Dean of the Faculty of Science in 1902. There, until 1921, when he retired, Dr. Harvey-Gibson made many valuable contributions to science. He acted as an examiner of botany in Aberdeen University in 1893, and was assistant examiner in the University of London Science and Art Department in the year 1896-1897. He also held appointments as examiner in the universities of Glasgow and Durham, and filled a similar rôle to the Pharmaceutical Society of Great Britain. He was sixty-nine years of age. The passing of Professor Harvey-Gibson reminds us that the Nor'-East Neuk of Scotland has sent out to the world a large number of scientists who had the happy knack of imbuing in those around them an intense love for natural history. Harvey-Gibson was an outstanding figure among them. His teacher, the late Dr. James W. H. Trail, one of the most lovable and gentle of men, who for four decades occupied the Chair of Botany in Aberdeen University, did valuable work in this respect. Wherever he saw the spark of a desire for knowledge in natural history, he very quickly kindled it into flame, and he fostered these principles in his pupils. Thus throughout the whole world there are and have been pupils of his, like Harvey-Gibson, carrying-on the good work. Dr. Trail, in his day, gave valuable assistance and encouragement to the Aberdeen Working Men's Natural History Society—a replica of which few towns or cities can boast. We are also reminded that the Nor'-East of Scotland gave us from the ranks of the humblest folks, men who earned a wide reputation for their knowledge of the flora, fauna and geology of their respective districts. There was Thomas Edward, the Banff shoemaker and naturalist, whom Smiles made famous; the Kincardineshire weaver, John Duncan, whose botanical survey of the valley of the river Don, which flows through Aberdeenshire, is unique. His specimens, the results of years of labour and research, now hold an honoured place in the botanical department of Aberdeen University. Then there was George Sim, the Aberdeen naturalist and antiquary. His shop in Castle Street, Aberdeen, was a place of pilgrimage for the antiquary, botanist, biologist and zoologist. A little farther north, the name of Hugh Miller, the eminent geologist, looms large.

Joseph Thrower.—His many friends will hear with deep regret of the demise of Mr. Joseph Thrower, on Sunday, June 9. Seventy-five years of age, he commenced his horticultural career in the gardens at Sandringham, then but recently acquired by King Edward VII. Afterwards, he spent two years in Paris, in a private garden, and on his return to England, entered the service of Messrs. Wm. Bull and Sons, of Chelsea, and was with them for nearly forty years, acquiring during that time a whole circle of friends and acquaintances. Later, he went to Mr. L. Russell, of Richmond Nurseries, and finally, in 1918, he took up a traveller's position with Messrs. Sanders, of St. Albans, with whom he remained until his death. During his long career he acquired an extensive knowledge of plants, particularly of stove and greenhouse subjects, and was often referred to when an occasional old time plant was shown. Possessor of a kindly, genial nature, a deep sense of humour, and the happy faculty of pointing his remarks with an appropriate anecdote, he will be widely missed, both in London and the provinces.

ANSWERS TO CORRESPONDENTS.

FIRE IN TULIPS.—*F. W. S.* The Tulip stems and foliage are infected with Botrytis tulipae, which causes "fire" in these plants. The symptom mentioned is one of the lesser recognised symptoms of this disease. Cut down and burn all infected stems. Lift the bulbs and examine them for small black bodies (sclerotia) on the outer scales, discarding those with sclerotia. Do not replant in infected ground.

LABURNUM WITH YELLOW, CREAMY-PURPLE AND PURPLE FLOWERS.—*G. R. L.* Your Laburnum is L. Adami, one of the most interesting trees in cultivation, being what is known as a graft hybrid. It originated in Mr. Jean Louis Adams' nursery at Vitry, near Paris, in 1825. The purple Broom (Cytisus purpureus), was grafted on a common Laburnum, and later flowers of a colour intermediate between those of the stock and scion appeared on the plant. A few years after this, another remarkable phenomenon took place, and it commenced sporting back to its parents, producing branches here and there of pure Laburnum vulgare and pure Cytisus purpureus. This accounts for the three distinct types of flowers on your tree. The validity of the above account was doubted until it was proved possible to produce graft-hybrids. A graft-hybrid between the Tomato and Black Nightshade was obtained by Professor Winkler, of Tubingen, and the several forms of Crataego-Mespilus present other instances. These graft-hybrids are called "chimaeras"—they appear to be a mixture of the tissues of the parents (under the microscope the tissues of the two are discernible), rather than a genuine fusion of the one parent with the other.

MELON AND CARNATION DISEASED.—*W. H. M.* No parasitic fungus was found on the Melon plant. The trouble may arise from injudicious watering and ventilation. The Carnation foliage is affected with stigmonose, which arises from the injection into the tissues of the plant of an irritant from the attacks by aphides, thrips and red spider. Keep down these pests by fumigating and forceful daily syringings with clear water. Red spider was present on the foliage. The Begonia leaf infested with mite was not enclosed. If mite is present, dip the plants in a nicotine soap wash.

NAMES OF PLANTS.—*G.* 1, Rose Double Yellow Banksian; 2, Phillyrea latifolia var. ilicifolia; 3, Orobus variegatus; 4, Pyrus floribunda var. atrosanguinea; 5, Libertia formosa; 6, impossible to name, send a fully developed specimen; 7, Olearia linifolia; 8, Berberis vernae; 9, Syringa (Lilac) Rubra de Marly; 10, Syringa (Lilac) Souvenir de Louis Späth; 11, Jasminum primulinum; 12, Olearia odorata.—*G. G. T.* Rubus deliciosus.

TOMATOS DISEASED.—*J. R. D.* It is quite impossible to diagnose the cause of the injury from the meagre specimen enclosed. The trouble may probably be traced to unhealthy root action. The tip of the shoot is free from any pathogenic organism.

REMARKS.—All Pyrethrums are now arriving in very large quantities, in both single and double varieties, but are somewhat varied in quality and price: the variety Eileen Robinson, a single pink, is very fine. Carnations, although fairly plentiful, have been of poor quality, good blooms being scarce. Roses have met with a good demand but, like Carnations, the first grade blooms are soon cleared, therefore prices still remain firm. Among Irises, the best blooms are from home-growers, Imperator (blue) being most plentiful; good white and yellow Irises are scarce. Very large consignments of these blooms have been arriving from Cornwall and Guernsey, but they are not well packed and many blooms arrive in a damaged condition and have to be sold at very low prices in order to clear. More Gladioli are on offer, including some very good blooms of the large-flowered varieties. Blue and pink Cornflowers are lower in price owing to increasing supplies, as also are Iceland Poppies. Sweet Peas have been more plentiful, but, like all other lines throughout this department, best grades have been limited and soon cleared. The newest arrivals in this department are Coreopsis, blue and pink Larkspurs, large white Daisies, and white Pink Her Majesty; a few bunches of Statice sinuata from home-growers have been on sale.

REMARKS.—There has been little fault to find with the demand generally this week. The weather has been good and most sections report active conditions. In the choice fruit section, Grapes, Peaches, Nectarines, Figs and Canteloup Melons are all in demand. Strawberries are selling well, although values of forced Strawberries are naturally affected by the increasing supplies from the Southampton district. Gooseberries are plentiful and prices lower, but considering the ample supplies available from the west of England, as well as Kent, prices are fairly good, especially in face of the competition of Dutch berries. The stocks of Australian Apples on hand are sufficient for the demand at present prices, and the tendency is easier. Oranges are available from South Africa, Brazil, California and Spain, and lower figures are expected in that section, although warmer evenings should have a bracing effect on values. Some excellent Cherries are being marketed from Italy, and find buyers at comparatively high prices. Apricots from Spain are more plentiful and sell fairly well. Bananas from Jamaica, the Canary Islands and Brazil sell freely at the moment. Tomato supplies are heavy for the time of the year and prices are at a comparatively high level; Cucumbers also are doing well. Asparagus has shown much improvement in values as compared with recent levels, and it is to be hoped these conditions will last for the short period that the cutting has to continue. Forced Peas, Beans and Marrows have been costly, although supplies have not been short. Mushrooms are abundant and prices are on the low side. New Potatos from Spain, Jersey and Cornwall are selling rather too cheaply to bring much satisfaction to the producers. Salads continue to sell well, and the supplies of green vegetables generally are ample for all requirements.

GLASGOW.

An improved demand for cut flowers helped to steady prices last week, except in the case of Irises, which were cheaper owing to excessive supplies; ordinary blooms were worth 2s. to 4s. per dozen bunches of 6's, and white, special qualities, 5s. to 6s. Tulips are nearly over for the season, the varieties being limited to William Saunders, at 9d. to 10d. for 12's; Clara Butt, 6d. to 9d., and yellow, 7d. to 8d. Gladioli were dearer, The Bride realising 1s. 2d. to 1s. 6d.; and Maiden's Blush and Blushing Bride, 1s. 4d. to 1s. 6d. Roses and Carnations fluctuated between 3s. and 4s. 6d. per dozen; Arums (Richardias), 2s. to 3s.; L. longiflorum, 3s. to 4s.; Pyrethrums, 1s. to 2s. 6d., special, 3s. to 5s.; Lily-of-the-Valley (inside), 1s. 6d. to 2s. per bunch; outside, 3s. to 4s. per dozen bunches; double Stocks, 1s. to 1s. 6d.; Anemones, 1s.; Nigella, 1s. 6d.; Paeonies, 1s.; Sweet Peas, 4d. to 1s. 3d.; Lilac, 6d.; and double white Narcissi, 3d. to 5d.

Business in the fruit market also indicated signs of expansion. Cheddar Strawberries sold from 1s. 9d. to 2s. 3d. per lb.; home-grown Melons, 9s. 6d. each; Peaches, (locally grown), 1s. to 1s. 6d. each; hothouse Grapes, 3s. 3d.; Pineapples, 3s. 6d. to 4s. each; Apricots, 12s. 6d. to 17s. 6d. per box; Cherries, 12s. to 16s. (20 lbs.); Gooseberries, 3d. to 4d. per lb.; Grape Fruits, 28s. to 32s. per case according to counts; Apples, Oranges and Pears remained unchanged.

Home-grown Tomatos are arriving in larger quantities and prices dropped to 10d. per lb., with best grades up to 1s. 1d. Asparagus sold at 3s. to 4s. 6d. per bundle; Scotch Lettuces, 2s. to 4s. per dozen; Dutch, 1s.; Cucumbers, 5s. to 7s. 6d.; home-grown Peas, 2s. 6d. per lb.; Guernsey Peas, 1s. 3d.; Guernsey Beans, 1s. 3d. to 1s. 6d.; Radishes, 3s. to 4s. 6d. per dozen; Carrots and Turnips, 1s. to 1s. 2d. per bunch; Syboes, 6d.; and Mushrooms, 2s. per lb.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 61·4°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, June 19, 10 a.m. (Greenwich time). Bar. 30·3. Temp. 72°. Weather, warm and fine.

Heterosis.

THE phenomenon of inheritance now distinguished by this title includes, incidentally, one of the most fundamental in the whole range of biology—the survival value of sex in the scheme of Nature. Why has the commingling of the tissues of two separate individuals become—apparently—the highest expression of evolutionary endeavour? It would seem that Nature experimented. In the beginning the asexual method of reproduction was tried; and still persists—very effectively too—in the lower organisms. Next, sex appears in the hermaphrodite form, first, absolute within one individual, and then, modified so as to effect the bringing of another individual into the reproductive effort. Then, the sexual differentiation takes the shape of two distinctively fashioned individuals. Finally, crowning the whole edifice we have, in man, an implanted aversion to the consanguineous union. Before the days of Mendel, Darwin was content with a mediaeval conception. "Nature abhors self-fertilisation," he said, and proved the "law" for plants in his book *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom.* But with the emergence of the science of Genetics, based as it is on the extension of Mendel's unit character hypothesis to include practically all the phenomena of heredity, including even the inheritance of sex, Darwin's "law" provides no explanation; no more than its prototype—"Nature abhors a vacuum"—explained the rising of water in the pump! We venture to think that neither heterosis, nor its cognate—loss of vigour on "selfing" (inbreeding in animals)—has, hitherto found a complete Mendelian explanation. The eminent Abbot and his successors have, no doubt, established, with an almost wearisome iteration, that the three to one ratio holds in the case of "qualitative" characters within a species group. But in the case of "quantitative" characters the proof is by no means so complete. The best that can be stated appears to be that the inheritance of such characters as physical dimensions, etc., has the appearance of being regulated by segregating factors; provided, always, that a multitude of additive allelomorphs of the same nature is postulated. But statistical confirmation is wanting, for, as Johannsen originally showed, environmental "fluctuations" in a family cannot be disentangled from the genetic mutations supposedly caused by segregation of allelomorphs. And, further, the chromosome hypothesis necessitates great economy in the number of segregating units. Again, as both Punnett and Engledow have demonstrated, parental dimensions have a puzzling way of disappearing from the F_2 descendants. However the theory stands, the crude fact remains that the scientific breeder, so far, has failed to control quantitative characters in the manner that has so often distinguished his practical successes with qualitative units. The failure is doubly unfortunate from the practical standpoint, for it is the former that are most important economically; yield and vigour of plants; amount of milk and flesh in cattle; and egg production in poultry, are examples of characters in which the practical man is interested and in regard to all of these scientific work has not, so far, given any results. The loss of vigour that so often follows the first step in scientific plant breeding—selfing the F_1—alone constitutes a formidable obstacle well illustrated by what followed when the geneticists in the U.S.A. attempted to breed an improved Maize plant. The pure line plants produced by continuous selfing are puny; although recessive defects have been bred out, the pure plant is useless commercially. When, however, two pure lines are crossed, heterosis comes into play. The heterozygous F_1 is even more vigorous than the existing commercial strains. It should be explained that, normally, the Maize of the farm is wind-pollenated and heterozygous to a degree. Unless, then, the farmer (who usually grows his own seeds), by taking rigorous precautions keeps two pure lines going, and grows them side by side the year before he requires seeds (an "unpractical" proposition), genetical science is of little use to him. The theory relating to heterosis most in favour at the present time is that vigour is the result of a number of dominant factors and that the excess vigour of the F_1 between two pure lines is due to the meeting in one individual of a greater number of such dominants than are present in either parent. The weakness of this theory, however, is that if it be correct, then it should be possible to fix vigour by breeding a pure dominant; but so far, a plant containing dominants in the homozygous form has not been found. If the dominants, moreover, are linked, as they might conceivably be, the chances (statistically) against the occurrence of such an individual are so great that an endeavour to get one is, practically, not worth making. The fact, therefore, seems to be that, so far as theory is concerned, we can do little more than modernise Darwin's dogma, and state that "Nature abhors homozygotes," recognising, at the same time, that man may, with advantage, disregard the teachings of Nature by keeping alive the self-pollenated cereals and in stock-breeding, practise inbreeding as one of the best methods of purifying and fixing improved breeds of domesticated animals! These observations have been prompted by a paper* that has just appeared in the leading American journal concerned with Genetics. In this paper heterosis is treated as one of the factors which determine the stability of a species under evolutionary stress and the straight assumption is made that the phenomenon accompanies heterozygousness without any attempt being made to evaluate it in terms of Mendelian factors. Incidentally, it is unfortunate that research on heterosis and its cognate inbreeding seems to be almost exclusively confined to the U.S.A. The subject attracts comparatively little attention here, although, as we have attempted to show, the want of a solution is likely to be a serious hindrance to the progress of genetic science in its economic aspects.

Our Supplement Plate.—The Lewisias rank among the choicest of the alpine garden plants which America has given us, and among them, L. Howellii, an illustration of which we have pleasure in presenting as a Supplement Plate to our present issue, is outstanding, being by no means difficult to grow and very free-flowering when afforded congenial conditions. The Lewisias are sun-loving plants and do best when grown in sunny crevices between rocks, in perfectly-drained, gritty loam, and with an abundance of soil-moisture during the summer months; during the winter it is advisable to protect them with a pane of glass placed overhead. L. Howellii forms an attractive rosette of fleshy, narrow, oblong leaves, which are crinkled at the margins, and produces, during late May and June, several sprays of beautiful star-like flowers, pink in colour, striped with buff.

Roses from the Royal Gardens.—It is the practice of Her Majesty the Queen, each Alexandra Day, to send Roses from the Royal Gardens at Windsor to Christie's, where they are sold by auction in aid of the Queen Alexandra Fund. This year the two bouquets of Roses sent realised £2,098; the blooms were sold singly, the bids ranging from two guineas to £100 for each flower. During the last eight years these sales of Roses at Christie's have realised not far short of £20,000.

Parasites for Controlling the White Fly.—Notices have appeared drawing attention to the distribution of white fly parasites by the Experimental and Research Station, Cheshunt, acting under the auspices of the Empire Marketing Board. Glasshouse owners have been asked to write for particulars to the entomologist of the above Station, but this is undesirable, because it multiplies the work. All that is necessary is for the owners of glasshouses infested with white fly, to state the number of glasshouses attacked. Consignments will be sent by return, so long as the supplies are available. The parasite is a Chalcid Wasp which lays its eggs within and destroys the young stages, known as "scales" of the greenhouse white fly. The parasite itself is entirely harmless to plants, and depends upon the white fly for its existence.

Jones-Bateman Cup for Research in Fruit-growing.—In 1920, Miss L. Jones-Bateman of Cae Glass, Abergele, presented to the Royal Horticultural Society a valuable Silver-gilt replica of the Warwick Vase, to be used for the encouragement of fruit production. It is accordingly decided to offer it triennially for researches in the growing of hardy fruits, Figs, Grapes and Peaches, in the open or under glass, and it is available for award in 1929. Candidates should submit accounts of their work by October 31. The work dealt with must have been carried out by the candidate in the United Kingdom mainly during the past five years. The Cup will be held for three years by the successful candidate, who must give a bond for its safe return, and when the Cup is relinquished the holder will receive a commemorative Gold Medal. The holder will be eligible to compete on the next or any succeeding occasion. The Assessors will be three, two appointed by the Royal Horticultural Society and one by the National Farmers' Unión, and they will report to the Council of the Royal Horticultural Society upon the originality and comparative potential value to the fruit-growing industry of the work of the candidates. The Council of the Royal Horticultural Society will award or withhold the Cup at its discretion.

---

* "Genetic Equilibrium and Selection," by W. B. Kemp. *Genetics*, 14-1-85.

Lauriston Castle and Grounds.—In formally opening Lauriston Castle and grounds to the public on Thursday of last week, Lord Provost Sir Alex. Stevenson remarked that it was only in 1920 that Cramond was brought within the City of Edinburgh, and since then they had opened a public park of thirty-two acres; Lauriston Castle grounds, extending to thirty-three acres, and the adjoining Lauriston farm, which extended to 196 acres, had been purchased, so that the Town Council of Edinburgh were now responsible for no fewer than 260 acres of open spaces in the Cramond district.

Honour for M. Turbat.—We are pleased to learn that M. Eugène Turbat, the head of a famous Orleans nursery firm, and Secretary of the Fédération Horticole Professionelle Internationale, has been elected Mayor of Orleans. We heartily congratulate M. Turbat on his well-merited civic honour.

Trials at Wisley.—The Royal Horticultural Society will conduct trials of autumn-sown Cabbages and Onions in its Gardens at Wisley during the coming season. Varieties for trial (one packet of each variety) should be sent to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, by July 15, 1929.

Horticultural Club Outing.—Arrangements have been made for the annual outing of the Horticultural Club, to take place on Friday, July 5. By the kindness of Messrs. J. Cheal and Sons, a visit will be paid to their nurseries at Crawley, and after lunch the party will proceed to Nymans, the residence of Lieut.-Col. Messel, to inspect his beautiful gardens. On arrival at Crawley, Messrs. Cheal will kindly provide refreshments, and lunch will be served at the George Hotel, Crawley. Lieut.-Col. Messel has kindly offered to provide an alfresco tea on the lawn at Nymans. The journey will be made by motor-coaches from Bush House, Aldwych, at 9.45 a.m., and the return journey will be made about 7 p.m. Applications for tickets, price 10s. 6d. each, should be made, not later than July 1, to the Hon. Secretary, Mr. George F. Tinley, 855, London Road, Westcliff-on-Sea, Essex.

Jealott's Hill Research Station.—The new Agricultural Research Station of Imperial Chemical Industries Limited, at Jealott's Hill, Warfield, Berks., will be formally opened by the Rt. Hon. J. H. Thomas, M.P. (Lord Privy Seal) on Friday, June 28, before a distinguished company. The new research station is stated to be the finest of its kind in the world. It comprises two farms, Jealott's Hill and Nuptown, the area of the former being 360 acres, of which 160 are under the plough; the latter consists of a grass holding of seventy-six acres. The estate is thirty miles from London on the south of the Thames, midway between Windsor and Wokingham. The Jealott's Hill Station is the new research headquarters of Nitram Limited, the distributive and research organisation for the farm fertilisers side of Imperial Chemical Industries. It is equipped with magnificent laboratories for analytical work of all kinds, such as the examination of soil and fertilisers, and for research into such subjects as animal nutrition, biochemistry, botany, plant physiology, bacteriology, and general microbiology. At the laboratories there will be displayed both apparatus and equipment used for the investigation of soils, fertilisers, crops, etc., and also special demonstrations of some of the methods used in testing soils. There will also be a cinematograph display illustrating the intensive system of grassland management. After the opening ceremony, visitors will be able to inspect any of the many research activities of the station. The experiments themselves will be explained by special demonstrators.

Mr. F. Capp.—The Professional Gardeners' Association, which has now a membership of over two thousand, was started ten years ago, at Wakefield, by Mr. F. Capp, who for the past eleven years has been gardener at Nostell Priory, the residence of the Hon. Charles Winn. Saturday, June 1, was the seventieth anniversary of Mr. Capp's birthday, and the occasion was fittingly marked. Nearly two hundred members of the P.G.A. and their wives, from the Leeds, Harrogate, Huddersfield, Bradford and Halifax branches, met at Nostell, and began a pleasant programme by an inspection of the Priory Gardens (by permission of the Hon. Charles Winn). The weather was brilliantly fine.

MR. F. CAPP.

Mr. Capp conducted the visitors through the extensive and picturesquely situated gardens, where the visitors were especially interested in the sound practical arrangements designed with a view to providing continuous supplies of varied produce. The vineries, Peach-houses, Fig-house and Tomato-houses were much admired, and the Bananas aroused considerable interest. The outdoor attractions included a splendid Rose garden. In the course of the tour, the party traversed the beautifully wooded walks, amid the gold of the Laburnum, the white blossoms of the Thorns, and the glories of the Rhododendrons. At the conclusion of the tour of the gardens, the party set out for Wakefield, where a substantial repast was awaiting them at Webster's Café. At the conclusion of the meal, Mr. McCormack, of Harrogate, President of the Association, who was supported by Mr. George Reid, of Gomersal, Secretary, and members of the Committee, wished Mr. Capp many happy returns of the day. In responding, Mr Capp said this was one of the proudest days of his life; ten years ago, he started the Professional Gardeners' Association, at Wakefield, and since then it had grown wonderfully; it had headquarters at Leeds and branches in various parts of the country. Later, the company were entertained by Mr. Capp. The President spoke in high praise of Mr. Capp's devotion to the welfare of the Association, and said they all valued his attendance and counsel at the meetings of the Committee. To celebrate this auspicious occasion, Mr. Capp had been made an honorary life member, and they desired to present him with a gold badge as a memento of the event, and a token of the respect and admiration of the members of the Professional Gardeners' Association. The inscription on the gold badge states that it was presented to Mr. Capp on his election as honorary life member and to celebrate his seventieth birthday. A vote of thanks to the Hon. Charles Winn for throwing open his gardens to the visitors, and to Mr. Capp for showing them round, was proposed by Mr. Micklethwaite (Huddersfield), seconded by Mr. Kelk (Bradford), and supported by Mr. Fletcher (Wakefield). Mr. Capp commenced his gardening career under his father, and afterwards served at Elsham House, Grantham; Clumber, Worksop; High Ashurst, Dorking; Plawhatch, East Grinstead; Hall Place, Maidenhead; and Oak Dene, Holmhurst, Dorking; and eventually had charge of the gardens at Newport House, Eardisley; Wexham Park, Slough; Paddockhurst, Crawley; Paddington Manor, Winchcombe; Colney Hall, Norwich; and Charters, Ascot, before becoming gardener to the Hon. Charles Winn, at Nostell Priory.

Holland House Gardens.—The Gardens of Holland House, Kensington, will be opened to the public, by kind permission of Mary, Countess of Ilchester, from 2 p.m. to 8 p.m. on Saturdays, June 29 and July 6 and 13, in aid of the West London Hospital and the Crippled Boys' Home. The charge for admission will be 1s.

Handbook of Manchester Parks and Recreation Grounds.—Public interest in the parks and recreation grounds of Manchester is fostered by the City Corporation and, to further this interest, the Parks and Cemeteries Committee has recently issued a second edition of the excellently illustrated *Handbook of the City Parks and Recreation Grounds*, by W. W. Pettigrew, V.M.H., the General Superintendent, in which the numerous open spaces are described, and much interesting data given concerning their purposes and special activities. The work commences with a brief outline of the history of the Manchester Parks; Philips Park and Queen's Park, in Manchester, and Peel Park, in Salford, were purchased by public subscription in 1845; the two former parks were presented to the municipality in the same year, suitably laid laid out at the expense of the subscribers, and formally opened to the public the following year. Only two open spaces—Ardwick Green and Alexandra Park (1868)—were secured during the next twenty-five years, but by 1895 the number had increased to twenty-three, although, as many of these were only small areas, the total acreage only amounted to 403 acres. It was in the next quarter-of-a-century—from 1895 to 1920—that the greatest progress in providing pleasure grounds and open spaces in Manchester was made, for we read that during this period the number of open spaces increased to seventy-six, the greatest acquisition being Heaton Park, Manchester's largest pleasure ground. During this period also, Platt Fields (ninety acres), Broadhurst Playing Fields (eighty-four acres), Cringle Fields (fifty-four acres), Brookdale Park (forty-three acres) and Debdale Park (forty acres) were added. Since 1920 two more parks have been opened to the public—Fog Lane Park (forty-eight acres) and Chorlton Park (twenty-nine acres)—making the total area of open spaces in Manchester 1,654 acres; stated by Mr. Pettigrew to be 446 acres short of the ideal set up by modern experts and approved by the Manchester City Council. Mr. Pettigrew outlines the policy adopted by the Committee in the development of these parks and recreation grounds, which may be grouped into four distinct types:—(1) children's playgrounds, pure and simple; (2) playing fields, where the greater part of the area is devoted to the provision of the requirements of organised games—football, hockey, lacrosse and cricket; (3) described as district open spaces, and laid out with bowling greens, tennis courts and grassy spaces where children can play, and (4) pleasure grounds, which embrace the largest parks. The development of games and sports in the Manchester parks, and the present curriculum, are dealt with in detail, as also are the "Children's Playgrounds," and organised visits of children to the parks; in fact, the full facilities and activities of Manchester parks and open spaces are reviewed with from A to Z in this excellent publication, the second half of which is devoted to detailed descriptions of the individual public parks. The *Handbook* is excellently illustrated throughout, and extremely well printed. We recommend it not only to the inhabitants of Manchester and the surrounding districts, and to those who may visit Manchester and be desirous of inspecting its lovely parks, but to Park Superintendents and others associated with the maintenance of parks throughout the United Kingdom, to whom it would convey many useful hints and much valuable information. It should be of special value to the Park Superintendents who will be visiting Manchester on the occasion of the Parks Superintendents Conference. The *Handbook* may be obtained from the General Superintendent, 38-40, Lloyd Street, Manchester, or from any of the head gardeners at the principal parks, price 6d. each.

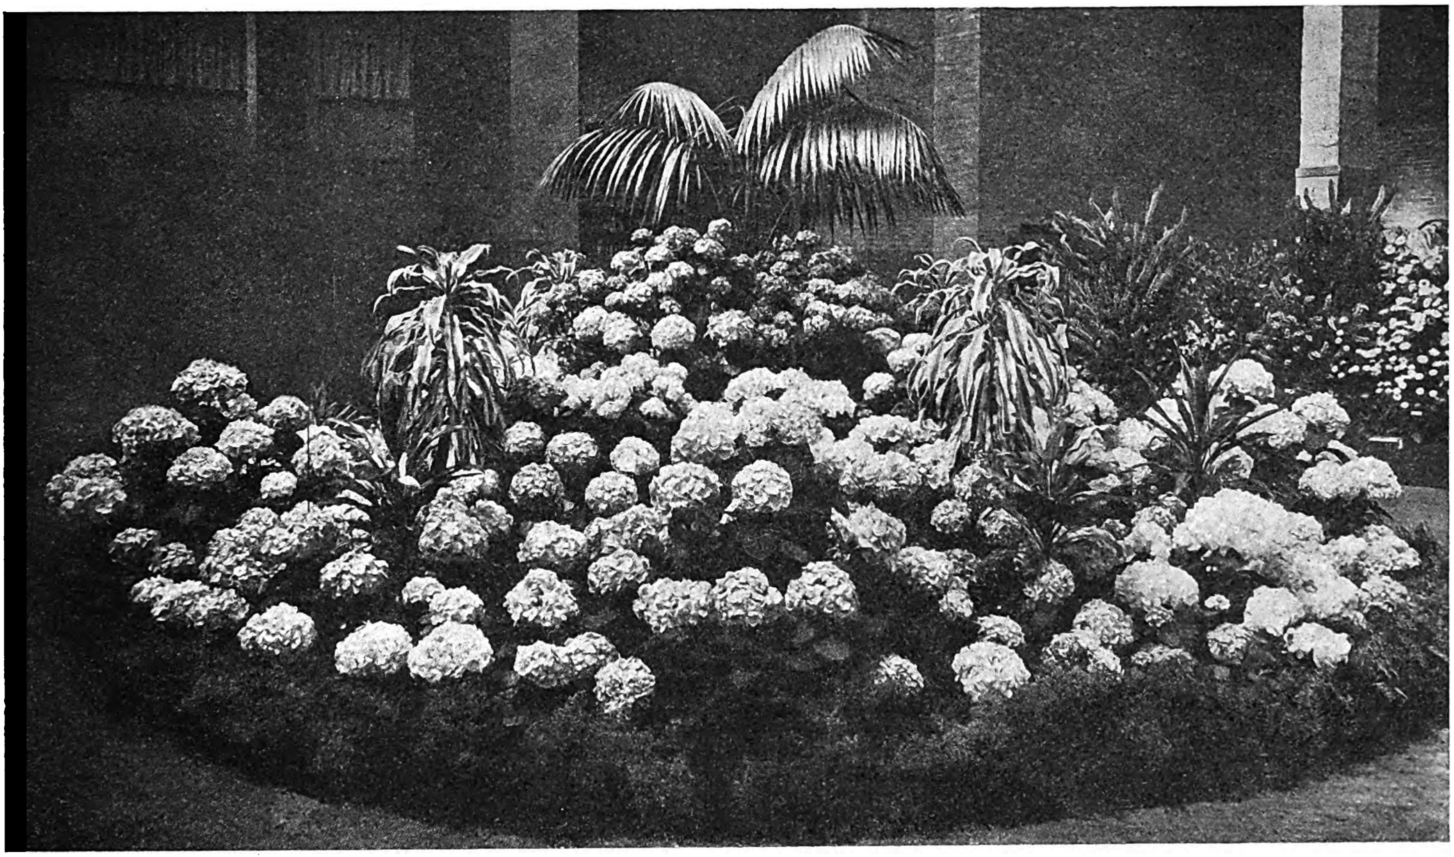

FIG. 230.—GOLD MEDAL GROUP OF HYDRANGEAS EXHIBITED BY BARON BRUNO SCHRÖDER (GR. MR. E. T. HENDERSON), AT THE R.H.S. MEETING OF JUNE 11.

(see p. 453.)

The National Sweet Pea Society.—During the next few weeks this special-flower Society has a full programme of events. The Floral Committee will meet at Birdbrook, Halstead, Essex, where Messrs. Robert Bolton and Son are growing the trials of new Sweet Peas, on Tuesday, June 25, and the annual outing of members to inspect the trials is fixed for the following day. Members from the south will leave Liverpool Street Station by the 10.3 a.m. train for Birdbrook, where they will be entertained to lunch by the kind invitation of Messrs. Robert Bolton and Son. This year the Society has an unusually large number of novelties at the trials, and in addition to these, Messrs. Robert Bolton and Son are growing all the Classification varieties and those especially recommended for garden decoration. In another part of their grounds, Messrs. Robert Bolton and Son have several hundreds of their own novelties which will also be open to inspection by members of the National Sweet Pea Society. The Annual Show will be held in the new Horticultural Hall, Westminster, on July 2 and 3. There will be an official lunch for members and their friends in the restaurant at 12.45 p.m. on July 2. The cost of tickets is 3s. 6d. each, exclusive of wines. The following week there is to be the Provincial Show of the Society in conjunction with the centenary of the Norfolk and Norwich Horticultural Society at Norwich, on July 11 and 12. The headquarters of the Society, during the period of the show, will be at the Royal Hotel, Norwich.

Appointments for the Ensuing Week.—TUESDAY, JUNE 25: Royal Horticultural Society's Committees meet (two days); Royal West Renfrewshire Horticultural Society's meeting. WEDNESDAY, JUNE 26: Lincolnshire Agricultural Society's Exhibition (three days); Wadhurst Gardening Association's Rose and Sweet Pea Show. FRIDAY, JUNE 28: Streatham Rose and Sweet Pea Society's Exhibition. SATURDAY, JUNE 29: Belgian National Sweet Pea Society's Exhibition (Brussels, three days); Leeds Paxton Society's lecture; Worcester Park Horticultural Society's Show; Wallington and District Horticultural Society's Exhibition; Romsey and District Gardeners' Association's Exhibition.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Cheltenham Horticultural Exhibition.*—It is a source of gratification to observe the yearly improvement in the management and success of provincial horticultural exhibitions. A few years since they were almost invariably got up and managed by interested parties, *i.e.*, by proposing exhibitors, whose object was not the advancement of horticulture, and the collateral arts and sciences connected with it, but to so arrange the prize and censor lists as to ensure to themselves the lion's share of the awards. As a natural consequence of such injudicious management, societies of the kind have always proved very ephemeral; and considering the little good and the large amount of bad feeling they engendered, such a result was little to be regretted. In some few instances, however, a different end has been aimed at. Perhaps no provincial exhibitions have equalled (certainly none have surpassed) those of Cheltenham. Not contented with throwing them open to the United Kingdom, they have opened them to all the world; and, by offering liberal prizes, encourage competition, and make it worth while for first-rate growers to bring their productions from a distance. An exhibition took place at Cheltenham on Tuesday and Wednesday last, which would have done no discredit to London. The stove and greenhouse plants were numerous and fine; Heaths good; Orchids choice, healthy, well-grown, and in respectable quantity; and of plants with ornamental foliage there was quite a legion. The only drawback was in the Pelargoniums, which, though abundant in quantity, were, with one or two exceptions, very poor and ill-grown. On the first day, the plants were exhibited in the usual way, classed according to their kinds; but, on the second, a new feature was tried, which was evidently a step in the right direction. The plants were all rearranged, each exhibitor's in one great mass by themselves. Prizes were offered in five classes, and the exhibitors had the option of showing their plants in any one of the classes they pleased. The appearance of some of the groups, which were tastefully arranged, was very good; and we observed some very happy effects produced by combinations of Orchids with Pelargoniums, and the judicious admixture therewith of Ferns and other ornamental-leaved plants. The exhibition took place in the grounds of the old Wells, which, besides a very handsome and well-stored museum, contains, as an additional attraction for the season, a Crystal Palace on a small scale, containing a very nice little exposition of arts and manufactures. Altogether, a spirit quite up to the present day has been displayed by the inhabitants of Cheltenham. We recommend their doings as an example to other towns, and in their future trials heartily wish them success. *W. D. Gard. Chron., June 24,* 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Anguloas.—As the strong-growing Anguloas, such as A. eburnea and A. Clowesii, are now passing out of flower, the plants will require some attention at the roots, while those plants which failed to produce flowers may be repotted as the new growth advances, for fresh roots are developed when the growth is a few inches high and any repotting is best done at that stage, *i.e.*, just when the new roots are pushing out at the base. These Orchids are robust growers and soon exhaust the compost; therefore the plants will require to be repotted at least every alternate year, while, if the pots used are on the small side, annual repotting will give good results. A suitable compost for them consists of equal parts A.1. fibre and good fibrous loam, with a few dried Oak or Beech leaves, well broken up, adding crushed crocks or charcoal to keep it open. Well-drained pots should be used, and some rough material from the compost should be placed in first to prevent the finer portions clogging the drainage. Pot moderately firmly, keeping the soil just below the rim of the pot with the base of the growth just in contact with it, not buried. After repotting, the plants will thrive well at the cool end of the intermediate house, and the pots and surroundings should be moistened by damping occasionally. Very little water will be needed at the roots until the growths and roots are advancing, but as the pseudo-bulbs begin to swell ample supplies will be needed each time the soil approaches dryness. When growth is complete the water supply should be reduced gradually, as very little will be required to keep the plants in a normal condition during the resting season. The foliage should be examined frequently for scale, red spider, etc., which, if found, should be removed by careful sponging. The later-flowering varieties of A. Ruckeri and A. uniflora should be afforded treatment similar to the above as they pass out of flower.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Gathering Strawberries for Dessert.—The greatest care should be exercised when gathering these fruits for dessert, and only those that are well formed and ripe to the tip should be chosen. They should be detached with sufficient stalk to hold them by, and they should always be served with their own fresh foliage. I have found that the early afternoon is the best time to gather the fruits, for then the flavour and aroma are at their best. Fruits, however, that are to be sent some distance are best gathered in the early morning when sufficiently dry, as then the flesh is much more firm, and the flavour, to some extent, must be sacrificed. Strawberries for preserving purposes are generally "plugged" when being picked, but they are more quickly gathered with the calyces attached, and with the least amount of damage to the berries.

Apple and Pear Trees.—Trees that were top-grafted this spring should be examined, and where the scions are making growth, the wax should be removed, and the ligatures loosened so that the swelling of the stem may be unrestricted. Secure a small piece of cane to the stock and the graft to prevent injury from birds and wind. A few shoots from the stock may be allowed to remain until the growth of the scion is well advanced, and afterwards removed. Young stocks should also be examined, and the resulting growths from the scions secured to Bamboo canes. Young growths from last year's budded stocks are first secured to the four-inch piece of "snag" left when the stocks were headed down this spring, and later to Bamboo canes, every inducement to make clean growth being given. The summer pruning of all fruit trees on walls and fences should be proceeded with now, laying in any extension growths where needed. These extension growths should not be summer-pruned, and the same rule applies to the leader growths of bush or other trees.

Aphis and Scale.—These two pests attack the Cherry and Peach, the former causing the leaves to curl badly, and the latter sucking the sap and making the foliage filthy. Both may be got rid of by a soft soap and Nicotine spray. This spray should be applied in the evening and with some force, and is made up as follows: Dissolve 3 lbs. of soft soap by boiling, and pour into it 1 oz. of pure Nicotine, then add the mixture to ten gallons of water. In the event of a very bad infestation of scale the amount of water may be reduced to five gallons, but it is essential that this wash be applied in the late afternoon or evening, and that it is not applied to trees with fruits at the point of ripening. Nicotine, unlike arsenate of lead, does not remain for long as a poison on the fruits or foliage, but evaporates rapidly. To be quite safe, however, a period of ten days should elapse between the last spraying and the gathering of the ripe fruits.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Roses.—June is a busy month for the Rosarian, for close attention must be given to pests and diseases, and their immediate destruction. Although June is spoken of as the month of Roses, it is generally not until the end of the month or the beginning of July, that H.T. and T. Roses are at their best. This year, at the time of writing, they are later than usual. Aphides should be dealt with immediately they appear, in fact, if time can be found, the bushes may, with advantage, be sprayed, whether aphis is present or not, with an approved insecticide; prevention is always better than cure, and insecticides for such purposes are cheap. Mildew is a troublesome disease in some gardens, and if not checked soon disfigures the plants. Dusting with green sulphur when dew is on the foliage will keep it in check if done in time. Spraying with some of the approved mildew washes will have to be resorted to if the attack becomes really bad. On many soils growers are too lavish with nitrogenous manures, thereby creating soft growth and foliage that are more liable to attacks by fungus diseases; in such instances it is better to apply potash to the soil during autumn for, by doing so, foliage of a firmer texture is created, which is better able to resist attacks of disease. Constant use should be made of the Dutch hoe not only to keep the beds free of weeds, but to create a mulch of loose soil, which will conserve moisture. During the month disbudding should be attended to if good blooms are required. Remove the buds not required so early as possible, leaving two buds for a time on each growth in case one is damaged by caterpillars. During continuous drought it is advisable to water the beds well, and then loosen the surface of the soil with the hoe to conserve the moisture.

Rhododendrons and Azaleas.—Remove the flower heads of Rhododendrons and Azaleas to prevent them forming seed-pods; such a procedure makes a wonderful difference to the growth and flowering of young plants. Also inspect those grafted periodically in case dormant buds on the stocks begin to grow; these should be removed entirely, not merely cut over with a knife. Choice sorts may still be layered—a simple and sure method of propagation, although slow—for these subjects are always better on their own roots.

Lawns.—Lawns sown during early spring require a little special care at this season. If the grass is thin it should not be mown in the usual way, or the roots of the young plants will suffer from the effects of the hot sun. A useful practice is to mow such lawns with a side wheel mower without the grass box, leaving the short grass to act as a mulch. If too heavy, some of the grass may be removed the following morning, but if mowing is done at regular intervals, never allowing the grass to become long, it is seldom necessary to remove any of it unless dull, wet weather is experienced. It is important that the cutting knives and sole-plate of the machine are sharp and well set, otherwise damage may be done to the young plants.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

The Orchard House.—The fruits on early varieties of Peaches and Nectarines are now quite ripe, and if they have not been gathered, and later sorts are forward enough to allow the admittance of more fresh air, with lighter syringings, and a discontinuance of fire-heat, the fruits may remain on the trees. As early trees are cleared of their fruits they should be syringed well to clean them. As they have made their growth and still have the summer before them, the coolest and most airy part of the house will suit them for the present; later, they may be partly plunged out-of-doors where they may have plenty of light, air and water. Watering and syringing are most important; the roots should have full benefit of moisture through the night. Mulchings of fresh stable litter are as necessary as ever, and feeding with soot and liquid manure, not too strong, should be continued; watering and syringing in the evening gives the best results.

Later Houses.—Fruits have set well in these houses, and thinning to the number each tree is to ripen may be finished, as there is very little danger of fruits dropping on healthy trees in June. Ripe wood is the mainspring of success, and, assuming that the house has hot-water pipes running around it, the daily routine of syringing and ventilation must never be neglected. Pinching and disbudding may be done rather freely and the roots watered liberally. All fruit-bearing trees should be top-dressed with a compost of loam, bone-meal and decayed manure, and as the trees grow, the strongest shoots should be stopped at the fifth or sixth leaf, or longer, according to their vigour, and the space at command; the weak growths, especially those near the base of the trees, may not need pinching at all.

Cherries.—The ripe fruits of these should be protected from birds, and if required to hang some time, may be lightly shaded. Trees with ripe fruits should be kept fairly dry and cool, but the roots should not be allowed to get too dry, or cracking and shrivelling of the fruits of May Duke and other thin-skinned varieties may result when water is afforded. Biggareaus will withstand drought, but soon become unhealthy if allowed to suffer through lack of root moisture. Later trees should be well thinned, and any young growths kept closely pinched to three or four leaves.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Cyclamens.—Young Cyclamen plants, which were raised from seeds last autumn, should by this date be ready for placing in their flowering pots, the size of which will greatly depend on the strength of the plants under treatment. The largest and strongest plants require six-inch pots, but for the majority five-inch pots should be large enough. To be successful with Cyclamens good drainage is essential, for when in active growth the plants require copious supplies of water; where possible, rain water should be used. The compost may consist of two parts fibrous loam and one part leaf-mould, with the free addition of sharp sand, old red bricks broken up very finely, and bone-meal. Another point to remember is, be sure the young plants are kept free from aphis and thrips. Mild fumigations will clear the plants of the former but, if thrips have obtained a hold, it may be necessary to dip the plants in a safe and reliable insecticide. After potting, the plants should be grown near the roof-glass, preferably in a light span-roofed house, and shaded from bright sunshine. They may also be grown successfully in cold frames from now until the autumn, the lights being removed in the evening if heavy rains are not expected.

Azalea indica.—If a cool, shaded house is not available for these plants during the summer, a cool pit will suit them, and when their growth is completed they may be stood out-of-doors under a wall or hedge. During hot, dry spells, they should be syringed vigorously during the evening to keep thrips at bay, for these are very partial to this plant.

Primula malacoides.—This delightful plant is worthy of extensive cultivation under glass, as it ranks among the most useful of the Primulas for decorative purposes. Another point in its favour is that it requires to be grown under the coolest possible conditions, and is therefore suitable for amateurs who have a cool house from which frost may be just excluded. This Primula is very free-flowering and produces its flowers on stiff stems well above the foliage. Seeds sown now in a cool house will provide good plants for early spring flowering, the plants being grown on into four-and-a-half-inch pots, care being taken always not to over-water them.

Winter-flowering Pelargoniums.—Where Pelargoniums are grown to produce a display of flowers during the winter months, the plants should now be ready for their final potting. After this operation they should be placed in a sunny position. Water should be given sparingly until the pots are full of roots, and even then it is far better to keep the roots on the dry side, to prevent sappy growth.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Celeriac.—Plants that were pricked out some time ago will now be ready for planting out. Select a fairly moist position for them, and place them fifteen inches apart in rows twenty inches apart.

Winter Greens.—Seedling plants of the various Brassicas for winter use should now be ready for transplanting in their permanent beds:—Dwarf Savoys, for early autumn; Drumhead Savoys, for late cutting; and Drumhead Cabbages and the old favourite Winningstadt Cabbage for standing through the winter. If planted now they will have time to develop into good specimens by the time cold and inclement weather arrives. Another batch of Brussels Sprouts should be planted to provide a succession to those planted earlier.

Peas.—These are now growing rapidly and should have supports provided so soon as they are of sufficient height. Those that have been staked already and are growing freely, sometimes fall away from the supports, therefore they should be gone over occasionally and any loose growth tied in with Raffia. During dry weather a soaking with water every week should benefit them greatly, while the ground between the rows may be mulched.

Maize.—As growth advances, each Maize plant should be staked separately, as the plants are very liable to be broken down by the wind. Good stout stakes, five or six feet high, should be used, and the plants tied securely to them. During dry weather, give them ample supplies of water at the roots.

Tomatos.—Finish planting out Tomatos so soon as possible, staking the plants at once, and when they are established, attend constantly to the removal of side growths.

Leeks.—So soon as these are large enough, plant them out into ground that has been well dug and manured. Allow eighteen inches between the lines and nine inches from plant to plant, and after planting, water them well to settle the soil about their roots.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Celery.—The maincrop Celery plants should now be ready for planting out, and, if showery weather prevails, no time should be lost in planting. As previously stated, the plants should be separated with a large knife a few days before planting, to reduce the check in lifting. On heavy soil the trenches should be shallow, but on light soils, deep trenches give the best results. In either case, a good dressing of old manure should be dug into the bottom of the trench and the whole well trodden. Single, double or even treble line trenches may be made, but the first is preferable for ease in earthing up. If large quantities of Celery are wanted early in autumn, the variety White Plume, if planted closely together on the level on well manured land, blanches quite satisfactorily without earthing up, but it should be used before the approach of frosty weather. After planting, tread the soil firmly about the plants, and water them well.

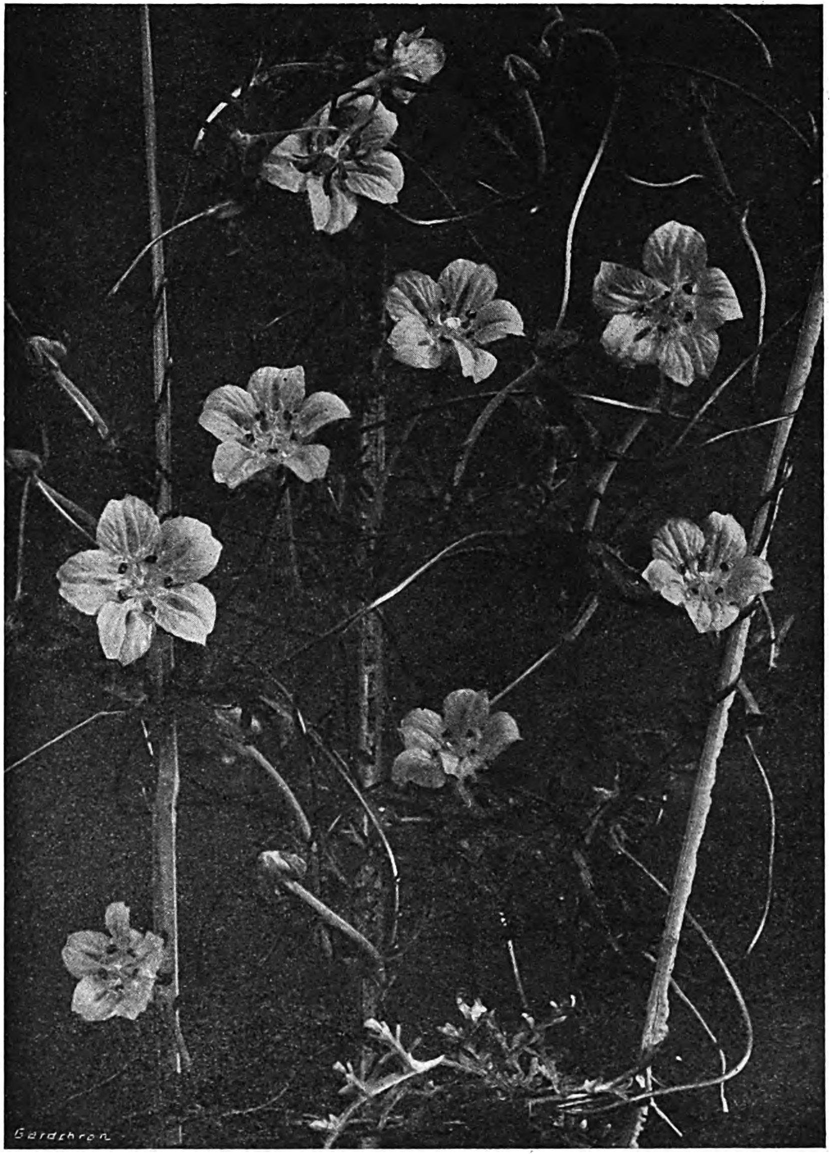

FIG. 231.—GRAMMATOCARPUS VOLUBILIS (SYN. SCYPHANTHUS ELEGANS).

R.H.S. Award of Merit, June 11. Flowers yellow. Shown by Major S. F. Harrison (gr. Mr. A. S. Hartless), Kings Walden Bury. (see p. 452.)

Asparagus.—The cutting from permanent beds should now cease, and the production of new growths encouraged by surface feeding and watering, so that the roots may have time to store up energy for next year's supply. As the stems lengthen, supply stakes and ropes for support before they get broken by wind and rain. Any blanks which occur in beds planted out recently should be filled up at once, and the ground frequently stirred either with the Dutch hoe or the cultivator. Brussels Sprouts which were planted in May should be hoed and then earthed up well, so as to provide support to the stems. French Beans may still be sown in a warm border from which an early crop has been cleared. Turnips, Carrots and Spinach should be sown frequently.

Roses.—Where Roses are subject to attacks of mildew they should be sprayed at intervals of a week or two with lime-sulphur. Stir the soil about them frequently and after the first crop of flowers, give a good dressing of dried blood or a good compound manure, and hoe it into the surface. To secure good flowers disbudding should be carried out regularly.

Chrysanthemums.—These, whether in pots or planted out-of-doors in beds, should be gone over now and again and have all unwanted growths removed, so as to strengthen those to be retained. Attend to staking, tying, watering and cultivating. Should leaf-miner appear, regular sprayings with Quassia extract usually keeps it in check, but it is important to wet the undersides of the leaves. The grubs can easily be killed by squeezing them between the finger and thumb so soon as detected. All biennials and perennials sown in May should be pricked out on well prepared ground in the open, allowing them sufficient space for full development.

NOTES FROM A WELSH GARDEN.

The passing spring has been notable for an abundance of blossom such as we have rarely seen before. If the severe winter is to be thanked for this, it is some consolation to feel that that season of evil memory did not confine its activities only to the debit side. Not only have subjects which usually give an average crop of bloom done well, but those which, as a rule, only flower feebly—or not at all—have been most satisfactory. Among the latter is Cytisus supranubius. This beautiful shrub managed to survive the frost unharmed, and it is now bearing quantities of its rosy buds and white flowers which scent the garden like a Bean-field. Leucopogon Fraseri, a dense, little, New Zealand, Ericaceous shrub, also escaped injury. Most of its nearer allies (Cyathodes) were killed, but its gloomy mound of dark spiny foliage has been brightened with tubular, ivory-white, honey-scented flowers for several winters. Vaccinium Mortinia is clustered with shell-pink bells which we do not often see here, and Leucothoe Davisiae, its pure white, erect racemes in striking contrast with the deep green foliage, is another of the shy flowerers which have done something for a shaky reputation. Many of the Gaultherias were reduced to a sorry condition by the frost, but G. Hookeri and the closely allied G. Veitchiana are flowering with vigour, and the more lowly G. perplexa and G. pyroloides promising a full crop of fruits.

Fragrance has been as generous as blossom, and a shrub like Lonicera syringantha, so often mediocre, has given us both with such liberality that for nearly two months it has been one of the most delightful objects in the garden. Growing in very poor soil, it has not exceeded five feet, but with every arching wand clustered with pale lavender, sweetly-scented blossoms, this shrub has excited the warmest admiration. The much smaller L. pyrenaica, although my specimen is only one foot tall, has also been flowering freely among other dwarf rock shrubs. Its pendulous trumpets, rosy-tinted white, are fully an inch long and half as wide, and very fragrant, Writing of fragrance, that of Clematis montana is not often mentioned, but throughout last month one of the most powerful scents in the garden emanated from a large mass of C. m. var. rubens. The countless blossoms of this fine plant gave forth a rich, musky aroma which at times was almost overpowering. A Philadelphus labelled P. Delavayi, and perhaps not typical, was the first of its race to flower, the clusters of bowl-shaped, white flowers having a more refined odour than that of many others of its race. A distinctive feature of this plant is the soft dove-grey with which the calyces and flower stalks are veneered. Among the best shrubby Spiraeas of later May is S. trilobata, an elegant bush of some four feet, the slender, arching branches bearing erect umbels of creamy-white blooms. In my modest collection of these subjects S. trilobata comes in after the earlier spring-flowering kinds and before S. bracteata. The latter, whose flowering season continues through early June, is such a handsome species and it stands out so distinctly among all others of its class, that one wonders why it is so seldom seen.

An interesting plant near the water is an American Liliaceous species, Chamaelirium luteum, which raises above a tuft of glabrous, spoon-shaped leaves numerous of one-foot flowering stems, each terminating in a dense spike of creamy-white blossoms. A nine-inch Globe-flower, labelled Trollius pumilus, Wargrave variety, is also a striking object, its small, finely-cut leaves being almost hidden beneath a blaze of golden-yellow blossoms whose sepals are reflexed. A hearty clump of Mimulus Lewisii var. alba is sustaining its reputation as one of the best of the less vigorous varieties, and it is pleasant to be able to record that the new Mimulus "Sunset," with scarlet flowers, came through the winter not less successfully than its parent M. Bartonianus. The delicate refinement of Primula flexilipes and P. chrysopa, the one with nodding bells of a moonlight pallor, the other bearing heads of soft lavender-blue, yellow-eyed blooms, will not be passed unobserved by lovers of good Primulas. Even although they flower at a season when they have to contend with so many of the big guns of their exalted race, these two, and I may add, the rich violet form of P. microdonta var. alpicola, should make a strong appeal to all who appreciate dwarf Primulas of easy culture. In contrast to the pale luminous yellow of P. sikkimensis is the sombre velvety-crimson of P. euprepes. The sweet-scented flowers of this weird species, in drooping, one-sided clusters on a two-foot stem, have narrow segments which are reflexed like those of a Cyclamen.

Meconopsis Baileyi is admittedly a difficult plant to place, its intensely vivid, kingfisher-blue striking so extraneous a note that it flings defiance at every other colour within range. But a group canopied by a thicket of Pyrus arbutifolia, whose corymbs of white flowers cast a silvery light, is the most pleasing of several efforts to accommodate this fine Poppywort. M. quintuplinervia, on the other hand, blends so sympathetically with the general run of semi-woodland subjects that a drift of its lavender flowers, several hundreds of them, has been surprisingly lovely for fully six weeks. Its gentle-toned, silver-lined bells have had for company Osmundas and other hardy Ferns, the orange Meconopsis cambrica, the starry flights of Saxifraga rotundifolia, some of the Sikkimensis Primulas, white and yellow Ranculuses and Stylophorum Franchetianum.

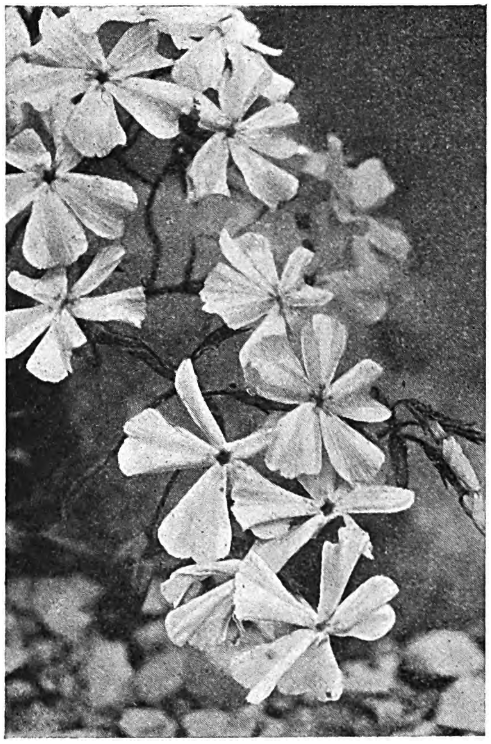

FIG. 232.—PHLOX CAMLA.

Always attractive and reliable, the Californian Irises are this year better than ever. Wonderfully free-flowering and affording a wide range of charming colours, these Irises thoroughly deserve to be better known. Nothing is more easily raised from seeds, the plants are slug-proof and hardy, and they carry on indefinitely in light, dry, stony soil, with full sun, only asking to be left undisturbed. The delightful I. gracilipes is also very willing here under similar conditions, but both this and its larger counterpart, I. tectorum, are so preyed upon by slugs that these pests are probably often the cause of failure with both species. The hardy form of I. japonica known as Ledger's variety is another Iris that will hold its own, even in June. Its sprays of flowers are singularly beautiful in their chintzy blending of blue, yellow and white, against the dark, glossy green leaves. I. chrysographes I have often been inclined to dispense with, since its lusty sheaf of "grass" has so often been out of proportion to the few and comparatively small flowers. But this year it has achieved wonders, its masses of rich violet, golden-veined blossoms which almost reach the tips of the slender leaves being really delightful.

Since it has become well-established in grass there is no more cheerful herb among the lesser woodland dwellers than Trientalis europaea, whose pearl-white, diamond-pointed stars have an elfin daintiness of irresistible sweetness. Mitella diphylla is another sylvan nymph attractive enough to make one wish to secure others of its genus. Here also is the chaste little Maianthemum Convallaria sharing a cool corner with the curious sea-green foliage of Jeffersonia diphylla, whose ephemeral blossoms are of earlier days; and again do covetous thoughts lean to a still more strangely beautiful species, J. dubia. Then what but eulogy can be expressed of that pleasant Japanese bantling, Tanakea radicans, which will shortly be waving above its little mat of heart-shaped leaves and thread-like runners six-inch plumes suggesting some tiny Astilbe. Nor will Vancouveria hexandra escape admiration, for it excels in the beauty of its foliage even among Epimediums, and its airy candelabra of waxen blossoms are the last word in delicacy and grace.

To conclude with a mention of a few oddments worthy of note and mainly among rock plants, an old clump of Lewisia Howellii has been a wonderful object for the past month, nearly 150 blossoms being counted at one time. Lithospermum Gastonii came through last winter and is flowering well, and both L. graminifolium and L. intermedium have made a splendid recovery after cutting back their frosted branches. Allium Ostrowskyanum and the rather later A. pedemontanum are among the most attractive of the dwarf species in pink, and if A. sibiricum cannot attempt to rival the above, it at least shows us what our own Cornish cliffs can do in the Onion breed. The pretty A. triquetrum, naturalised (if not indigenous) in parts of southern England, was nearly all destroyed just when it was in a fair way of over-running the whole garden. But a few of its graceful white-belled spikes appeared in time to join the exquisite Hyacinthus amethystinus. Aquilegia suaveolens, with a face of cherubic innocence and such a fox-like smell that its specific name must have been "writ sarcastic," has adorned a rock garden ledge for the past month. The true Phlox stolonifera, in a cool place, is a lovely plant not often seen, but always distinguished by its downiness, ramifying, thread-like runners and rose-carmine flowers on erect six-inch stems. But of all the dwarf Phloxes grown here none has won such unqualified admiration as P. Camla (Fig. 232), a recent creation of that magician among gardeners, Mr. F. W. Millard. There is something of the warm salmon-rose of P. Vivid in the flowers of this excellent novelty. But the large blooms, some being just over one-and-a-half inch across, are an even clearer, more appealing shade of that colour. An iris of fretted chevrons of carmine and a satiny texture add a touch of rare refinement and quality to the delicately-fluted, wedge-shaped segments of the corolla. The leaves are small, narrow and crisp, the stems red and in height no more than six inches. My plants proved quite hardy last winter, and they have carried an immense crop of bloom throughout May and early June. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

TREES AND SHRUBS.

ELAEAGNUS MULTIFLORUS.

Among the shrubs which are specially suitable for planting in coastal regions, Elaeagnus multiflorus (syn. E. longipes) ranks high, but it is not only as a subject for seaside planting that this shrub deserves recognition, for it is of sufficient charm to merit growing in any garden where space can be found for it.

E. multiflorus is a deciduous, or, in the milder districts, semi-evergreen shrub, very attractive in foliage, which imparts to the whole a silvery appearance, and also effective when in fruit, and although the flowers are not striking, they in no way detract from the good appearance of the shrub, and are delightfully fragrant.

It is a native of Japan and China, and was introduced to this country about the year 1862, being now fairly extensively grown. It is one of the hardiest members of this popular and varied genus, several species of which are frequently grown on account of their foliage, especially the evergreen ones. It passed through the last winter practically unscathed, and is now (early June) flowering freely, the wealth of flowers giving promise of an abundant crop of fruits, for which this plant is grown in Japan, as they are edible and, although acid to the taste are not unpleasant to some palates; certainly birds are fond of them and devour them greedily so soon as they approach ripeness.

E. multiflorus flourishes in exposed and sunny positions, in fairly light soil, and forms a rounded bush up to ten feet or more high and as much across, its young growths being covered with reddish-brown scales; in fact, the whole plant is more or less scaly. The growths are clothed with slender leaves, ovate or obovate in shape and tapering at both ends, the upper surface being green and the lower silvery and covered with tiny scales. The flowers appear with the new shoots, being produced in the leaf axils, either singly or in small clusters; they are apetalous, that is, devoid of petals, and, apart from their fragrance, are not attractive. The fruits, however, which hang on slender stems, impart to the shrub a handsome appearance during July, for they are usually produced abundantly; they are about half-an-inch long, oblong in outline, and rich, deep brownish-orange in colour.

VIBURNUM TOMENTOSUM VAR. MARIESII.

THE Viburnums in general are flowering freely this season, but none, in my experience, with such abandon as this variety of the Japanese Viburnum tomentosum, its spreading branches being wreathed with inflorescences, from the base to the crown of the bush.

V. tomentosum var. Mariesii is undoubtedly very charming, indeed, very striking, when in flower, its beauty being enhanced by the fresh, bright green foliage. The broad clusters of flowers are borne on two-inch stems which rise erectly along the whole length of almost every branch, the large and creamy-white, sterile flowers of the cluster surrounding a central mass of small, cream-coloured, perfect flowers. In contrast to the erect inflorescences, the leaves droop on either side of the branch, so that the general effect is very charming, additional colour being furnished by the reddish petioles of the foliage.

This variety, like the better-known and, perhaps, even more beautiful variety plicatum, is hardier than the type, and superior to it, and is worthy of note as an extremely attractive early June-flowering shrub. *M. W.*

ALPINE GARDEN.

CORONILLA CAPPADOCICA.

SOMETIMES called Coronilla iberica, this beautiful hardy perennial, a native of Asia Minor, is a member of the Natural Order Leguminosae, and flowers in June and July. Being of prostrate habit and profuse in flowering, it is an admirable subject for the rock garden, for it thrives in ordinary soil, and delights in a sunny position.

The large flowers, yellow in colour and typical of the Order to which they belong, are borne in umbels, as the name cappadocica, or "crown" suggests. Each umbel is composed of seven or eight flowers, and attains a height of approximately six inches from the ground. The green leaflets, nine or ten in number, are obcordate and ciliated, while the stipules are orbicular and finely-toothed.

Coronilla cappadocica may be propagated by division in October, or by seeds sown out-of-doors in April. Flowering at present on the rock garden here it makes a charming spectacle and fully justifies its inclusion. *Reginald E. Moore, University Botanic Garden, Cambridge.*

IRIS GARDEN.

IRIS ENSATA.

"ONE ocean of green, which in the end of May becomes a pale sea of blue. For its form is far better than elsewhere—generous in shape, and of the loveliest, softest blend of milky blue and lavender and cream and white, yet further enhanced by its delicious fragrance of Hyacinth." So wrote Farrer of that form of Iris ensata, growing in north-western Kansu, and, after looking on a well-grown clump here in England, one may realise the beauty of such a flower in masses, as he saw it.

The leaves vary in length from eighteen to twenty-four inches, overtopping the flowers by quite six inches; the leaf-surface is slightly glaucous, while there are about six prominent ridged veins on each side. The flower stems are flattened, bearing usually two flowers at the apex; the bracts are narrow, pointed, and sharply keeled, approximately three inches in length, and the pedicels are slender, that of the second flower on each stem being about double the length of the first. The ovary is marked by six longitudinal ridges and furrows, and is of a darker shade of green than the pedicel.

The underside of the haft of the falls is prominently striped with green, and this, being carried out into some of the veins, gives a creamy coloration to the upper surface; the latter has a white ground marked by pale lavender veining, particularly near the edges. The falls are oblong-oval in shape, about one-and-a-quarter inch in length, and have a pointed tip. The style-branches and standards are both of a delicate lavender tint, the former becoming almost white and transparent on the edge, with upright, toothed crests; the standards are over two inches from base to tip, three-fifths-of-an-inch wide, and taper to a blunt point.

The scent of the flower is most noticeable and, as Farrer stated, strongly resembles that of Hyacinths.

Farrer gave it as his opinion that this species should be grown under the driest possible conditions, fearing that too much moisture would encourage leaf and not flower production. However, provided the position is not shaded, the plant would appear quite at home, and flowers abundantly on a moist border.

Iris ensata occurs in various forms right across Asia, and has been figured in the *Bot. Mag.*, the *Bot. Reg.* and in Sweet's *Flower Garden*, under different synonyms. The original name was published by Thunberg, so far back as 1794, in *Transactions of the Linnean Society*. **B. O. M.**

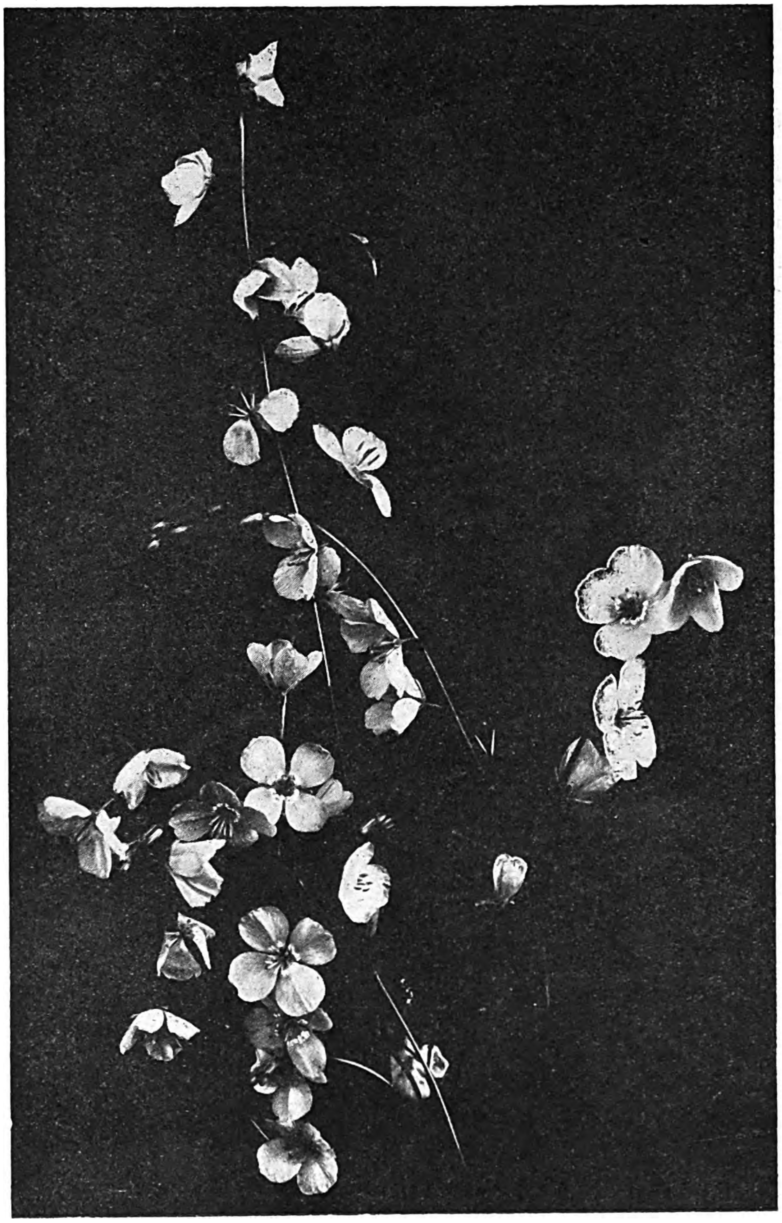

FIG. 233.—HELIOPHILA LINEARIFOLIA.

R.H.S. Award of Merit, June 11. Flowers blue with white centres. Shown by Mr. T. Hay, Hyde Park. (see p. 462.)

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

LANCETILLA EXPERIMENT STATION, HONDURAS.

THREE years ago the Tela Railroad Company established, on the Atlantic coast of Honduras, Lancetilla Experiment Station, which is devoted to the testing of new plants of potential economic value in tropical America, and to the study of factors affecting growth and production of Bananas. The Banana is the chief article of export from the north coast of Honduras. The Tela Railroad Company and the Truxillo Railroad Company possess large plantations in the lowlands of Honduras, centering about Tela and Puerto Castilla, from which many millions of bunches of Gros Michel Bananas are exported annually. In some parts of the Honduran coast Sugar is produced for export, but this crop is of only minor importance.

Lancetilla Station is situated in the Lancetilla Valley, at an elevation of sixty-five feet, three miles south of the port of Tela. On each side of the valley rise steep hills, with a maximum elevation of 2,000 feet. The floor of the valley was formerly planted with Bananas, but these have been abandoned for several years, and the land has been invaded by coarse weeds and small trees. The adjacent hills are heavily forested except where small clearings have been made by native squatters for the cultivation of Maize, Beans, Rice and vegetables. Land thus cleared, by felling and burning the trees, is planted only one or two seasons, then left to grow up with shrubbery, which soon covers it thickly. In this state the land is known locally by the term "Guamil."

The virgin forest of the hills is very dense, but in steeper places the undergrowth is scant. The forest is composed of a wide variety of hardwood trees, the most abundant being Brosimum terrabanum (called here Masica), Virola (Myristica) species (Sangre), and Dialium divaricatum (Paleta). Mahogany (Swietenia, and Spanish Cedar (Cedrela) occur but sparingly. Many of the forest trees attain gigantic dimensions, especially the Ceibas (Ceiba pentandra), whose massive trunks are usually supported by broad, thin, bracket-like buttresses. There are many epiphytic trees in the forest, particularly wild Figs (Ficus) and Clusias, which in age kill their host plants and stand alone as huge trees. Large, woody vines or lianas drape many of the trees, noteworthy among them being a Marcgravia and several water vines, the chief of which, perhaps, is the Central American Grape, Vitis tiliaefolia. From a section about a meter long cut from the stem of one of these vines, there may be obtained a glass of potable water-like sap, which satisfies thirst.

The herbaceous flora of the forest includes many rare or otherwise interesting plants. Species of Heliconia, Costus and Calathea are abundant and often showy. Ferns and other cryptogams are plentiful, and epiphytic Orchids and Bromeliads are well represented. Among the Orchids I noted only a few showy ones. Vanilla (V. fragrans) is the commonest member of its family, the vines running to the tops of tall trees. Although Vanilla is frequent in the wild state in many parts of central America, I have seldom been so fortunate as to find it in flower, and the seed-pods are seen but rarely.

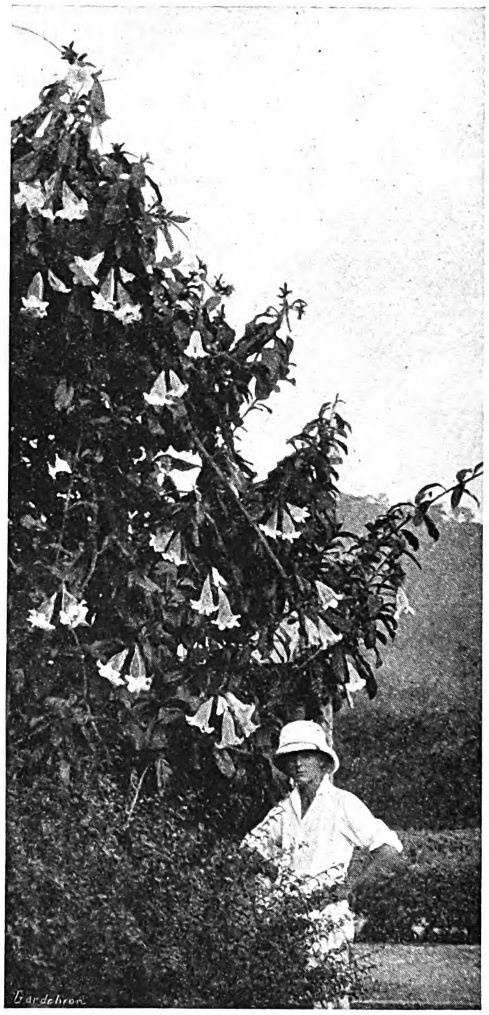

FIG. 234.—LANCETILLA: BEAUMONTIA GRANDIFLORA ON THE SIDE OF A SLAT HOUSE.

Palms contribute a conspicuous element of the vegetation. Most abundant and imposing is the Cohune, Corozo, or Manaca (Attalea Cohune), the largest North American Palm, which forms dense undergrowth on the hillsides up to 800 feet, and often fills clearings or pastures in the lowlands. Its leaves are used commonly as thatch for huts. The nuts are rich in oils, but so hard that its extraction is extremely difficult.

In low or swampy ground, Oreodoxa oleracea towers gracefully above the surrounding trees. On the hill slopes grow several Chamaedoreas, beautiful because of their slender, smooth, green stems, graceful leaves, and highly-coloured inflorescences and fruits.

The young inflorescences of the Chamaedoreas, enveloped in green spathes, resemble small ears of Maize. In central America the tender spadices, before they unfold, are used commonly as a vegetable, being dipped in egg and fried. They have a slightly bitter but agreeable flavour, and are delicious when properly prepared. The inflorescences are produced continuously and only a few cultivated plants are needed to insure a constant supply of this desirable vegetable. In some of the many central American species of Chamaedorea the inflorescences are too bitter to be palatable.

A low, slender Malortiea with perforated leaves is a curious and ornamental Palm, and the Geonomas, although of more sparing occurrence, add a pleasing element to the Palm flora. There are several formidably armed Bactris species, from one of which, known locally as Lancetilla, in reference to the broad, compressed spines, the Station derives its name. A small Bactris, which grows in dense clumps and is profusely armed with long, stiff, needle-like spines, forms impenetrable thickets in the coastal swamps near Tela.

The Panama-hat Palm, Carludovica palmata, which, of course, is not a member of the Palm family, abounds in the forests, but little use is made of it, either here or elsewhere in central America. Often it is associated with its relative, Cyclanthus bipartitus, whose curiously biparted leaves and screw-like fruits are certain to attract attention.

An outstanding member of the Honduran flora is Dracaena americana, the only American representative of its genus, a medium-sized tree, suggesting the tree Yuccas, with few branches, bearing large, showy panicles of small, white flowers, which are succeeded by fleshy, globular, orange-coloured berries. It is a plant well worthy of cultivation.

The Director of the Lancetilla Station is Mr. Wilson Popenoe, formerly of the United States Department of Agriculture, and well known for his activities in the introduction of tropical American plants into California and Florida, especially in the case of the central American Avocados. It is of interest to note in this connection that the Guatemalan rough-skinned Avocado (Persea americana var. drymifolia) grows on the hills above Lancetilla, where the trees attain a huge size. Cacao also is a frequent inhabitant of the forest. Both these plants are of rare occurrence in central America in a wild state, although both are general in cultivation.

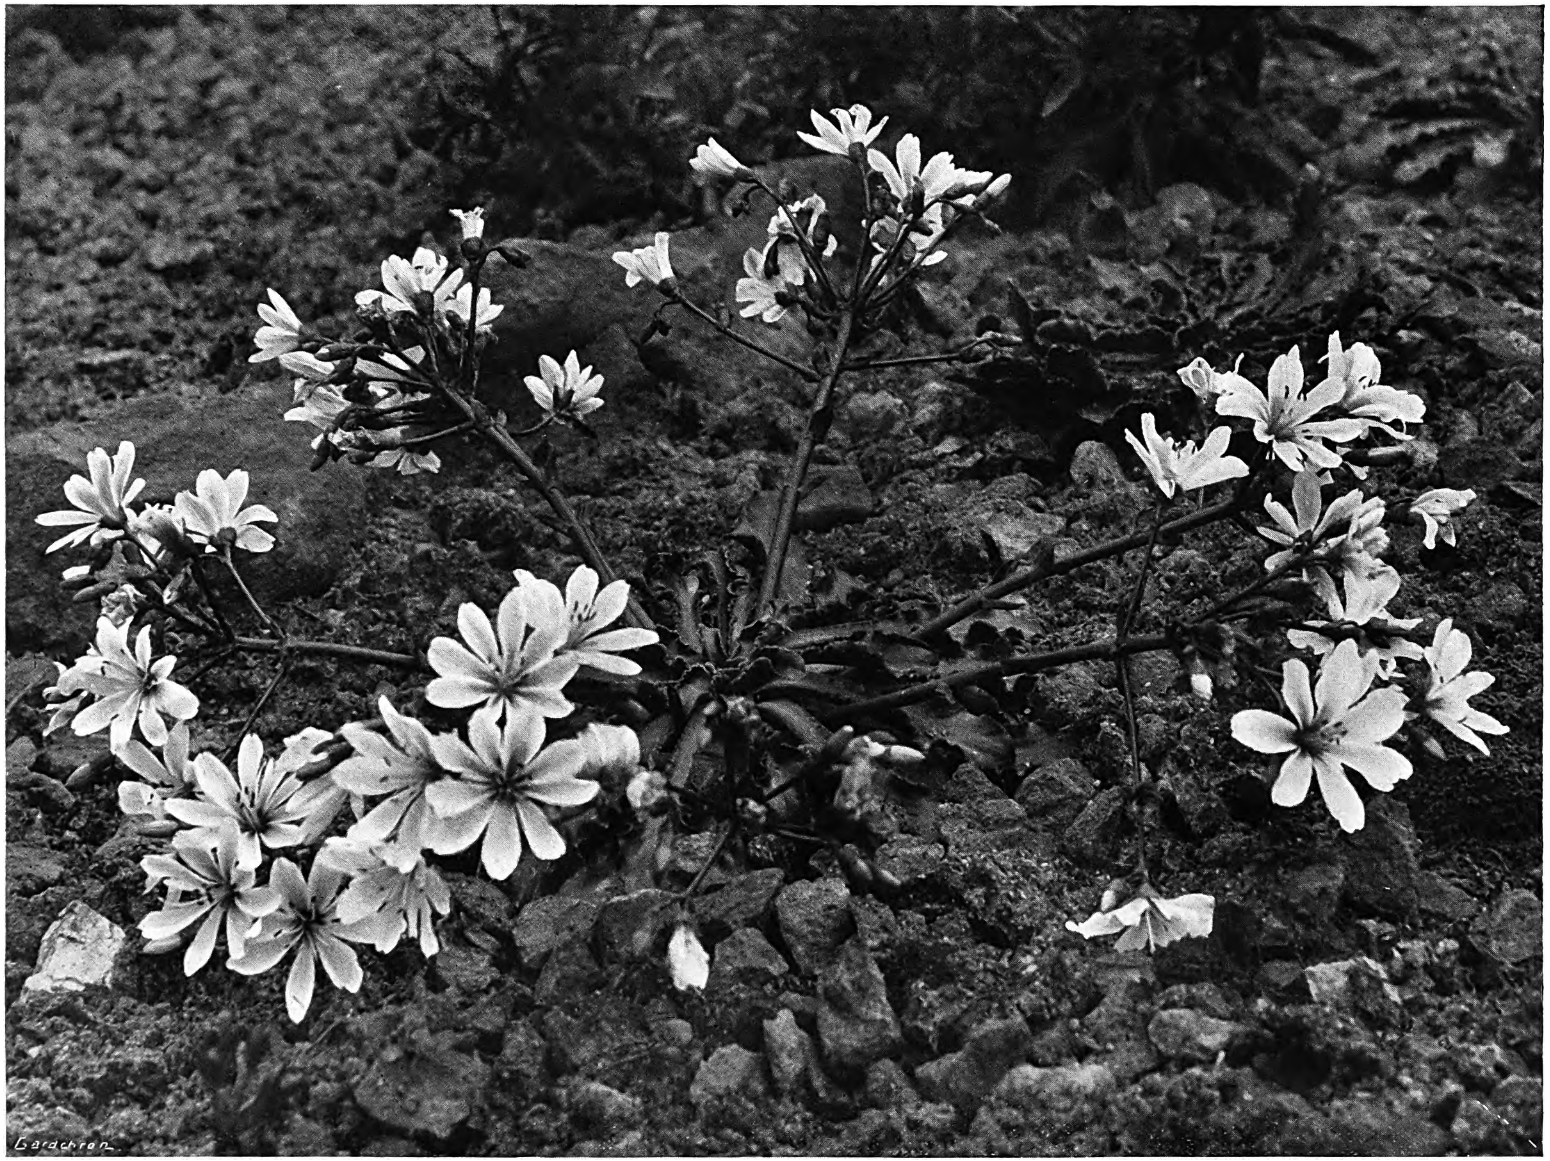
The Horticulturist of the Station is Mr. Alfred F. Butler, an old Wisley student, and formerly employed on the estate of the Hon. Vicary Gibbs, Elstree, England, under Mr. Edwin Beckett.

The Station possesses an adequate office building, living quarters, a plant shed, a small glasshouse, and a slat house for the growth of young, tender plants. Living conditions are exceptionally pleasant at Lancetilla because of the agreeable climate and the numerous modern conveniences available. To this the writer can testify most emphatically, after having had the privilege of passing there the winter of 1927-8, while engaged in studying the flora of the region, preparatory to the publication of a systematic report upon it.

There are extensive plantings at Lancetilla, another plantation near Tela, and still another at Quebrada Seca, some fifty miles inland, where the rainfall is less and conditions more favourable for the growth of certain plants. The precipitation at Lancetilla is heavy, sometimes so much as 120 inches a year. In one twenty-four hours during January, 1928, about fourteen inches of rain fell, with more on the succeeding days. Most of the rain falls from July to January, and in the spring and summer there is often a prolonged dry season. The temperature is frequently high, as is to be expected in the lowlands, but during the past winter it was delightful for most of the time, and blankets were a necessity at night.

Lancetilla Station occupies an attractive situation upon elevated, well-drained ground, with a beautiful view of the deep green hills up the valley into the far distance. The grounds have been planted with a large variety of ornamental and useful woody plants. Because of the short time since the plantings were begun, most of the shrubs and trees are still very small, but in this

Supplement to THE GARDENERS' CHRONICLE.



LEWISIA HOWELLII.

climate growth is so rapid that in a few years they will make an imposing display. Already the Bamboos, the Wood Oil Trees, Spathodeas, and some of the Palms, stand out conspicuously.

On each side of the path leading to the office has been planted a row of the Pejibaye Palm (Guilielma utilis), the plants already ten feet high. This Palm, almost unknown outside the limited area in which it is native, is, after the Coconut, the best of the central American species as a source of food. In Costa Rica it is planted abundantly about many of the country places, and the ripe fruits are in great demand during their short season. Two to three inches in diameter, when boiled they have a firm yellow flesh resembling that of a Sweet Potato, and in flavour perhaps superior to Chestnuts.

Comparatively little effort has been devoted to the importation of ornamental plants, those of economic value receiving chief attention. However, a variety of Palms is being grown successfully, among them being species of Areca, Arenga, Caryota, Chamaedorea, Cocos, Corypha, Elaeis, Geonoma, Kentia, Latania, Licuala, Martinezia, Thrinax and Zalacca. Other ornamental plants under cultivation are Ravenala; Bauhinias, especially that fine shrub, B. Galpini (Fig. 235), with brilliant orange-red flower clusters; Spathodea, sometimes called Tulip Tree, a desirable shade tree in this region because of its gaudy blossoms and rapid growth; Petrea arborea, the Purple Wreath, one of the most gorgeous of tropical American vines on account of its lavish display of long-persisting racemes of bright blue flowers; Beaumontia grandiflora (Fig. 234), with its large, white flower trumpets, so suggestive of the Daturas; Bougainvillaeas of several varieties; Thunbergia grandiflora, with rich blue blossoms; and a superb collection of large-flowered hybrid Hibiscus brought from Hawaii. The Codiaeum, Acalypha, and Nothopanax species, universal in central American gardens, have been omitted, and wisely so.

Since Bananas are of chief local interest, attention has been given to the introduction of varieties from widely separated parts of the world (Fig. 236). One of the handsomest ornamental plants cultivated at Lancetilla is Musa Uranoscopos, a dwarf plant forming clumps only four feet high, and producing large, bright red, erect flower spikes. The inflorescences are so similar to those of some of the Heliconias of the neighbouring forest that the relationship of the cultivated Musa with the members of the only American genus of the Banana family is easily recognised. The Heliconias bear so little superficial resemblance to the Bananas and Plantains that only the botanist would recognise their kinship.

Pineapples also have received attention at the Station, and forty-two varieties have been collected from remote regions. The Pineapples have been transplanted recently to the dryer region of Quebrada Seca, where Citrus fruits are grown successfully (Fig. 237).

A good-sized plantation of the Tung Oil Tree (Aleurites Fordii) has been made, and the trees have grown well. Specimens of the Chinese Wood Oil Tree (Aleurites montana) have developed even more rapidly, and already have reached a height of nine to twenty-two feet. The Japanese Wood Oil Tree (A. cordata) is also being tested.

Bombax and Ceiba species are being tried as a source of fibre. Balsa (Ochroma) trees grow luxuriantly in the valley, and spring up like weeds in every clearing. Besides furnishing in their seed-pods a soft elastic fibre, Balsa trees are noted for the extreme lightness of their wood, lighter than cork, which is exported from central America to the United States for the manufacture of life belts and the insulation of refrigerators. It is an amusing sight to see on the docks the loading of Balsa timbers. Until they are handled they have the appearance of very heavy logs, and one is startled when a labourer lifts in one hand a large Balsa log and raises it easily to his shoulder.

Rubber-yielding plants naturally are being tested here, and plantings have been made of the Cryptostegia species, of Para Rubber, and of Funtumia elastica. Central American Rubber (Castilleja elastica) grows wild plentifully in the vicinity. Some Castilla Rubber is now gathered in central America for export, and nearly all the wild trees in the forest bear the oblique slashes indicating that they have been tapped. Castilleja trees are often planted about the "fincas" as shade, and as a source of Rubber.

About forty-five plants, mostly Leguminous, have been tested in the grounds with a view to their utilisation as cover crops in Banana plantations. Some of them have shown great promise, but others which have proved useful elsewhere have been failures in Honduras because of unfavourable conditions of soil, climate or reproduction. Some of the plants have made but scant growth, while others have grown so luxuriantly that they have not only covered the ground beneath the Banana plants, but threatened to cover the Bananas themselves.

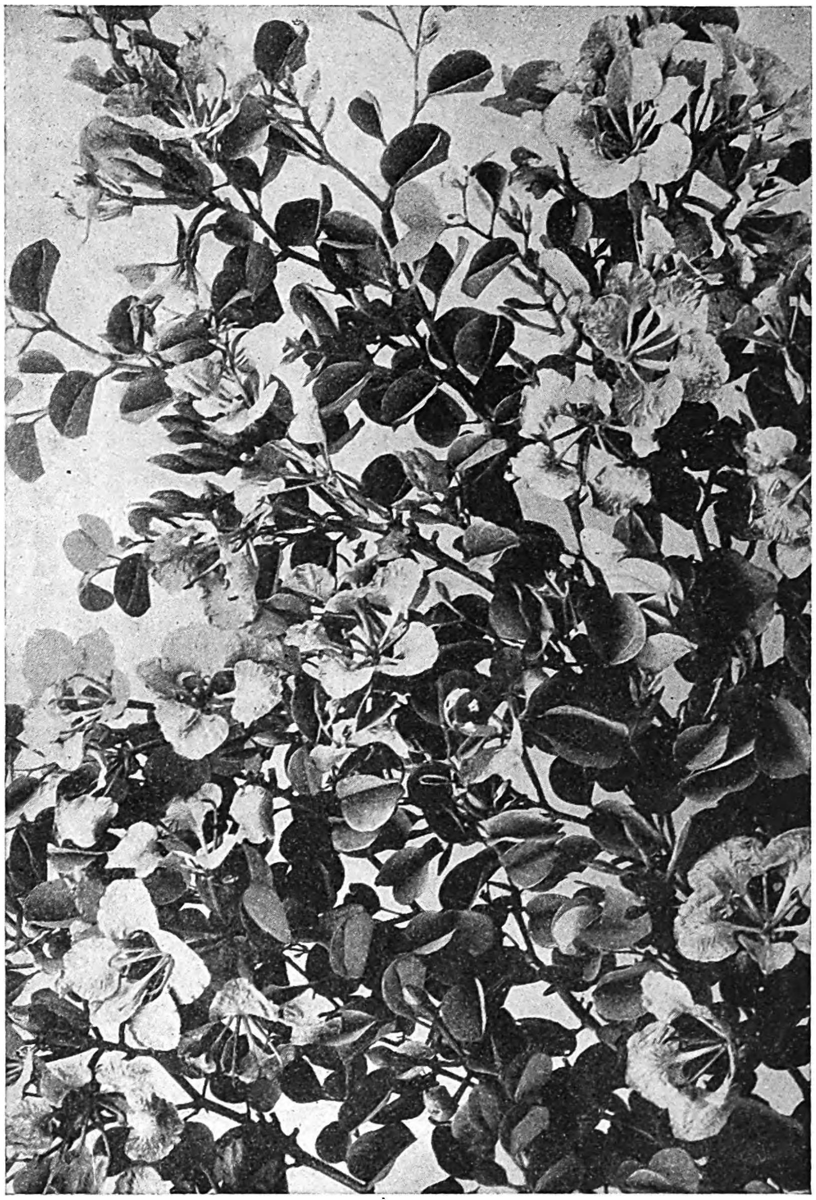


FIG. 235.—LANCETILLA: BAUHINIA GALPINI.

The permanent plantings at Lancetilla, according to a list recently compiled, include 370 species and varieties of plants of economic or ornamental value. The collection of tropical Asiatic plants is the largest to be found anywhere in America, and the same may be said of the representation in several other outstanding groups.

Some of the important fruit trees of the Old World tropics, which are little-known in America, are being tried upon a comprehensive scale. Many of the Asiatic species were obtained especially for the Station by Dr. O. A. Reinking during his travels in the East. Particular pride is taken in the large number of Mangosteen trees, whose growth is encouraging. One large Mangosteen tree established in the Tela region fruits freely, and there is, consequently, every reason for expecting that this famous fruit may be grown here successfully upon a large scale. The plantings of Mangosteen trees are the most extensive in America. Already 275 seedlings have been transplanted to the permanent grounds, and it is planned to increase the number to 375 during the present year. Eight other species of Garcinia, besides G. Mangostana, also are in cultivation here.

The collection of Mango varieties is a large and important one. The Mango is the favourite fruit of the native central American people, and since most of the trees growing in the region are seedlings of inferior quality, it would be of great benefit to improve the general quality of the fruits. The representation of Citrus fruits at Lancetilla is unequalled anywhere in this general region of the continent. The plantings of Lychee (Nephelium Litchi) have succeeded remarkably well, and the young trees, striking because of their highly-coloured new foliage, are growing rapidly.

Among the less well-known fruit trees which are being grown at Lancetilla are Anacolosa luzoniensis, the Galo; Artocarpus odoratissima, Averrhoa Carambola, Bouea macrophylla, Canarium commune and C. ovatum; Clausena lansium, Dillenia indica, Durio zibethinus, the Durian; Eugenia uniflora, the Pitanga or Surinam Cherry, a fine hedge plant, producing spicy-flavoured, red fruits; species of Euphorbia; Flacourtia Ramontchi, Gnetum Gnemon, Inocarpus edulis, Myrciaria (Eugenia) cauliflora, and species of Hephelium.

Two groups of trees which at first thought would seem out of place in the lowland tropics, are Castanea and Castanopsis, yet trees received from the United States Department of Agriculture and grown from seeds gathered in Yunnan by J. F. Rock, are thriving and making satisfactory growth. In the genus Castanopsis there are represented C. argentea, C. diversifolia and C. Hystrix.

Of Coffee there are fourteen species and varieties. Coffee is the most important export crop of the interior of central America, and that produced in these republics has long held an enviable position in foreign markets because of its superior quality. Coffea arabica, the only species grown commercially at the present time, is cultivated on a large scale only at altitudes of approximately 2,000 feet or more, but it is planted occasionally at lower elevations, sometimes even at sea-level, for household consumption.

The Asiatic timber Bamboos are well represented at Lancetilla, and extensive plantings have been made of some of them. Seedlings of Bambusa polymorpha and B. Tulda, when transplanted to the open ground, have reached a height of ten feet in less than a year. A native Bamboo of the Honduran coast, Guadua aculeata, is a striking feature of the local vegetation. It grows in swamps, often forming large clumps or dense thickets, and rising to a height of sixty feet or more, the stems having a corresponding diameter. It requires only a very few weeks for the giant stems to make their full growth. Sections of the stems are utilised at Lancetilla as flower pots. On the Pacific slope of central America the Asiatic Bamboos, which are planted commonly, furnish important construction material, many of the huts being formed of the heavy stems. On the Honduran coast I saw one hut whose walls were formed of sections of the local Guadua (called here Tarro) flattened out like boards. This type of construction is common in Ecuador, but I have never noticed it elsewhere in central America. Perhaps this example had its origin in South American influence.

A well-managed vegetable garden is maintained at Lancetilla, and another at Progreso, both kept by the gardeners in as neat condition as the curious Chinese gardens of Panama. Most of the vegetables grown are those familiar in northern gardens. Potatos, of course, do not succeed at low altitudes in central America, although they are planted extensively in the mountains, usually at elevations of over 5,000 feet. Tomatos, strangely enough, do not thrive at Lancetilla, although the common wild form, with small, Cherry-like fruits, grows in waste land in the vicinity. The cultivated plants are attacked by fungus and other pests, which make their successful growth impossible.

The vegetables most commonly grown along the Atlantic coast of Honduras are Maize, Beans, Onions, Garlic, Lettuces, Cabbages, Carrots, Radishes and Peppers. At Lancetilla several of the common Chinese vegetables are cultivated successfully. The Chayote (Sechium edule) a relative of the Cucumber, seems to succeed quite as well as in the highlands, where it is one of the favourite vegetables.

The most interesting of the vegetables grown at Lancetilla is the so-called Philippine Spinach —Talinum triangulare. This plant is really a native of tropical America, and grows wild in many parts of central America, but it seems to have been introduced into cultivation in the Philippines, and brought thence to Tela. The plant grows rapidly, producing an abundance of young leafy shoots which afford an excellent substitute for Spinach. The plant is easily propagated by seeds, and well deserves cultivation throughout the warmer parts of the earth. *Paul C. Standley, Field Museum of Natural History, Chicago.*

HAIR WORMS IN GARDENS.

AFTER warm showers, particularly during the spring and early summer, it is no unusual thing for the gardener to find on his plants a thin, hair-like creature resembling a miniature snake, twisting and turning in all directions. If he does not know what it is he naturally looks upon it as a foe, and fears that it may be very injurious. This will be the case more particularly when, as often happens, there are several at the same time. On occasion, they are so numerous as to have given rise to the idea that they have come in a shower, and have literally been brought by the rain.

All the old books and journals call these worm-like creatures Gordius aquaticus, and speak of them as though they all belonged to one and the same genus. This, however, is by no means the case. In appearance they resemble a piece of fine yellow silk, white cotton, or dark thread, varying in colour more or less with the species. They vary equally in length. The smaller forms may measure little more than half-an-inch, while the larger sometimes attain the length of a foot, although in general the dimensions are from two to four inches. Their colour is usually masked by the matter in the alimentary canal, but it is sometimes a rich yellow, at others dirty white or light brown. As is so often the case with the lower forms of life, they pass through transformations in which the larvae often differ widely from the mature forms. Even to-day, it is doubtful whether we have anything like an adequate knowledge of the group, since very little has been done with the species found outside the countries of Europe, while our native forms have never yet been studied exhaustively.

The following notes are not intended to be a technical survey, but may be of service to gardeners generally, and a guide to anyone who may wish to take up the study of a subject which will afford scope for original research. For such as read German the handiest and cheapest text book is the little volume of ninety pages whose title is given in the footnote.*

The Hair Worms may be regarded as near relatives of the Nematodes, some few of which they closely resemble, and are ranged in two groups. The first group (Mermithidae) consists of species of the genus Mermis, long, threadlike worms, not divided into segments as in the case of earthworms and fresh water worms, but looking like a piece of very fine catgut or glazed silk. Some of the species are only known at present in their embryonic or larval form, but there are two which frequently occur in this country and on the continent of Europe. In their free form, as found on plants in our gardens and elsewhere, they are quite destitute of mouth organs and other anterior accessories, and exactly resemble a living hair. They lay eggs, however which are very characteristic, out from which the larvae creep to find their way into the bodies of other larvae or insects, where they undergo their transformation. One form has been named contorta, on account of its habit of twisting itself around strands of grass or the stalks of plants. The male is usually small, and may be easily overlooked, but the female is usually about two inches long, whitish in colour, with a conical posterior extremity.

The second form (M. crassa) is, as its name implies, thicker and longer, often attaining a length of three to four inches. The larvae infest those of gnats and other insects which live in pools and still water, and it is in this larval stage that the feeding is done. The other two species which have been described are only known in their larval stage, and much work remains to be done before we can pretend to have mastered their life-history.

The other group (Gordiidae) is divided into genera of which three are usually recognised by zoologists. The best known of these, and the one which has given the name to the family, is Gordius. It recalls the Gordian knot. Only one species, the familiar G. aquaticus, is at present placed in this genus, and this sometimes attains a length of ninety centimetres, although it is only one millimetre (one-twenty-fifth-of-an inch) in diameter. The larva is found in the cockchafer and other insects. Paragordius is the name of the second genus, and Parachordodes of the third. Most of the species are of a brownish colour.

In order to distinguish the species special attention must be given to the following points. In the first place, one must observe the cuticle which may be smooth, covered with minute papillae, or marked with a fine network of crossing lines. Next in importance is the form of the posterior extremity, which may be forked, or have three processes. Then comes, finally, the presence or absence of a horse-shoe-shaped fold of the skin near the anus. The larvae, however, differ widely from the adult, and it would be necessary to give drawings in order to make the diagnosis intelligible (see *Gard. Chron.* for July 14, 1928, Fig. 16, p. 33).

I have received innumerable specimens belonging to the different species from every part of the British Isles, and think it probable that all the different species of Mermis and Gordius alluded to above are to be found in England. Probably the number would be considerably increased if the subject were taken up systematically by a student with sufficient knowledge and leisure. *Hilderic Friend, Solihull.*

PLANTS NEW OR NOTEWORTHY.

RHODODENDRON VANESSA.

(R. Souliei-Fortunei × R. Griersonianum.)

THIS hybrid was shown by Lady Aberconway and the Hon. H. D. McLaren, at Chelsea Show, and was awarded a First Class Certificate (see p. 384). It is the first hybrid from R. Griersonianum to be exhibited, and it has inherited many of the best characteristics of this fine species. The other parent is a hybrid between R. Souliei and R. Fortunei variety Mrs. Butler. The colour of R. Vanessa is a bright shade of salmon-pink; the plant exhibited was of dwarf habit, and bore nine trusses of flowers.

The cross was made in June, 1924; the seeds were sown in February, 1925; and the first flowers were produced in May, 1928. Such quick results, together with its unique colour, is a good augury of the value of R. Griersonianum as a parent. *P. B.*

NOTICE OF BOOK.

Debt Collecting without Tears.

THE sixth edition of this handy little manual* on collecting debts through the medium of the County Court, has been thoroughly revised and brought up to date, the whole volume being re-set in slightly larger type than that previously used, and the forms re-modelled. The result of the revision is a slightly larger book, but it is still small enough to be handy, while none of its good points—which we have noted in regard to previous editions—has been lost.

We may, however, without intending to cavil, point out that while it is useful to know the procedure in a County Court summons, there is a middle course between conducting a case entirely alone, and handing it over *in toto* to a solicitor, paying for his services a fee so high as to make it unremunerative to proceed at all. This middle course consists in having recourse to a firm of debt collectors—there are quite a number in London and in the larger provincial towns—who have made a special study of this branch of the law, and who, by reason of the large size of their practice, can charge the most reasonable fees, and put through their business with the minimum of delay. However, there are doubtless many business men who for some reason or other wish to know the ins and outs of County Court practice, and to them this little book can be cordially and whole-heartedly recommended.

THE IRIS AS AN ECONOMIC PLANT.

Owing to the circumstance that "orris-root" and not "Iris-root" is the title in general use, the fact is often lost sight of that Irises, in addition to being plants of great beauty and ornamental value, are also of some economic importance.

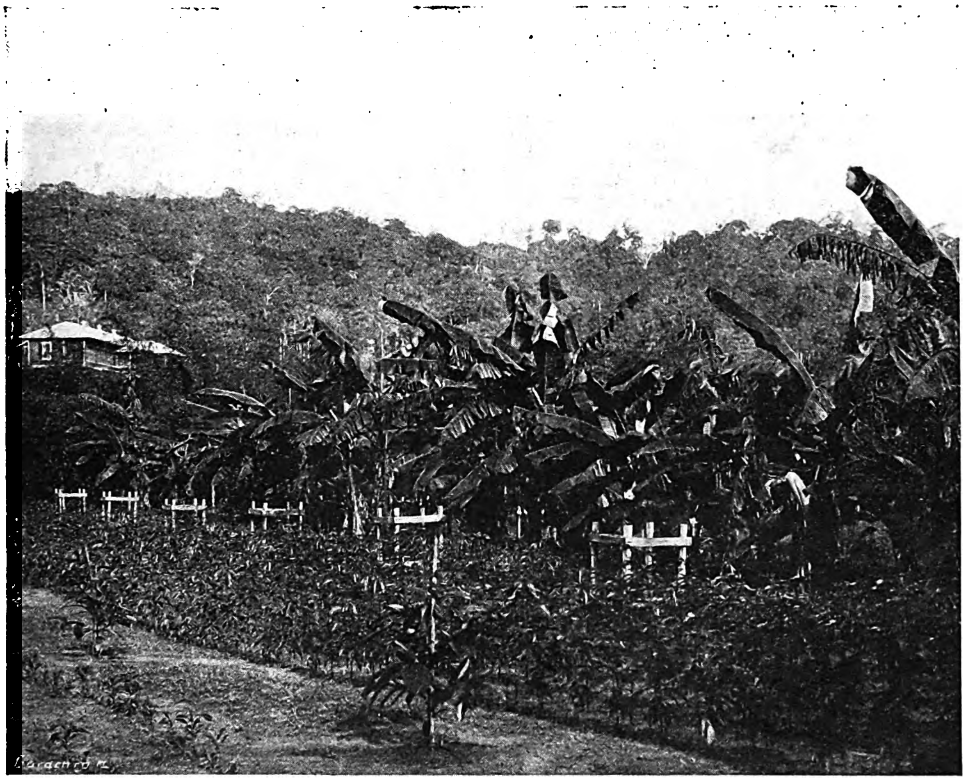

FIG. 236.—LANCETILLA: BANANA COLLECTION, WITH CITRUS SEEDLINGS IN THE FOREGROUND.

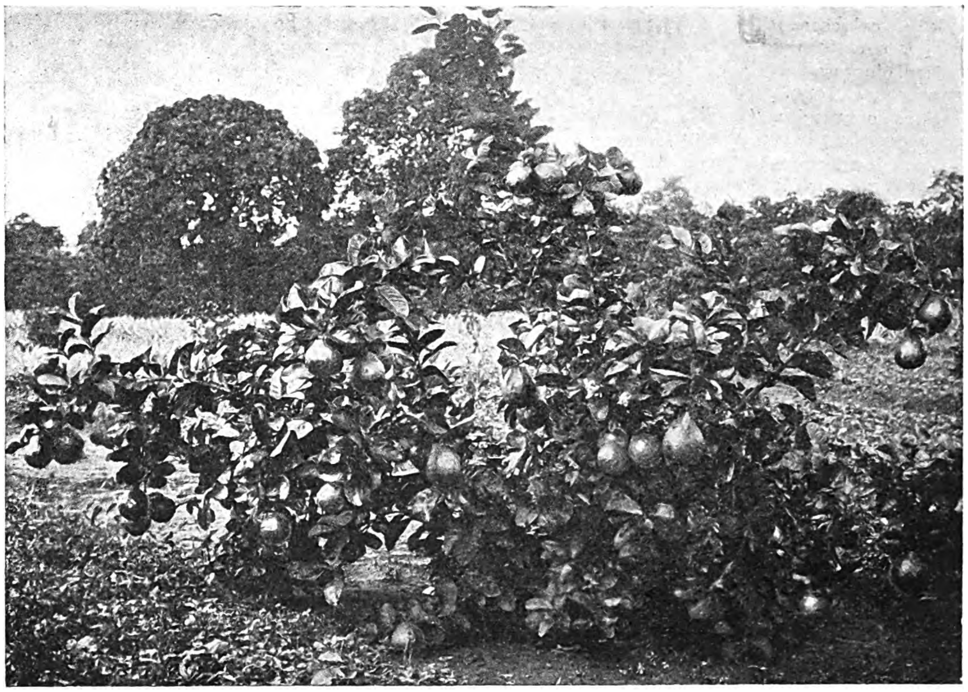

FIG. 237.—LANCETILLA: LEMON PONDEROSA AT THE QUEBRADA SECA STATION.

Irises are cultivated for their roots, or, more correctly, rhizomes, especially in Italy, the species grown for the purpose being Iris germanica, I. pallida and I. florentina.

The flowers are usually sold for ornamental purposes and the rhizomes harvested from June to August when they are well developed. The roots, strictly so called, and growing portions are removed, and the rhizomes immersed in water to cleanse them, after which they are peeled. As yet they have very little odour, the characteristic Violet-like fragrance only developing as a result of the slow drying process, which is effected, when the weather is favourable, by exposing the decorticated rhizomes, after washing, to the action of the sun's rays. In bad weather, drying is carried out in artificially-warmed and well-ventilated chambers.

The dried rhizomes are whitish in colour, hard in texture and variable in size. The best are obtained in Florence from I. pallida. These are very light in colour and deliciously fragrant. Other varieties are usually somewhat darker and not so odorous.

The rhizomes contain a considerable amount of starch, and, when they are powdered, yield a fragrant and very soft material of a light buff colour, which finds useful employment in the manufacture of dentifrices and toilet-powders. So-called "Violet-powder," for example, usually contains fifty per cent. or more of powdered orris-root, mixed with various proportions of such ingredients as Maize starch (Cornflour), talc, zinc oxide and boric acid. Orris-root is also used in the manufacture of Violet sachets and Violet-scented toilet soaps.

The Violet odour is a very rare one in nature, Acacia Farnesiana (Cassie) being one of the few plants whose flowers have a perfume at all resembling that of Sweet Violets. The Violet-like odour of orris-root is due to the very small amount of a specific substance, irone, which it contains. By distilling orris-root with superheated steam and condensing the vapours in long, air-cooled tubes, a small amount of an essential oil may be obtained, the yield being only four or five parts of oil, or even less, per one thousand parts of orris-root. This oil is a solid, fatty substance at ordinary temperatures, and is known as "orris oil concrete." It consists of about eighty-five per cent. of myristic acid, which is quite odourless, together with the odorous irone and traces of other substances. By appropriate means, the myristic acid can be removed, yielding a liquid oil consisting largely of pure irone. Naturally, this oil is very expensive, but there is a considerable demand for it for the manufacture of Violet scents.

To prepare these entirely from odorous material extracted from sweet Violets themselves would be prohibitively costly, owing to the fact that the amount of this material present in sweet Violets is microscopically small. Nowadays, the basis of most Violet scent is a substance called "ionone," which is synthetically prepared from citral, isolated from the essential oil of Lemon-grass (Andropogon flexuosus, a native of Madras, and A. citratus) and acetone. This substance, it is interesting to note, is isomeric with irone, which has also been made synthetically, that is to say, the molecules of the two substances contain the same number and sort of atoms but differently arranged in the two cases.

Owing to its relatively non-volatile character, the addition of a little orris-oil to a Violet-scent based on ionone, serves to fix the odour, making the perfume more permanent.

The distillation of orris-oil from orris-root is mainly carried out in the perfume factories of Grasse in the south of France, rhizomes imported from Tuscany being mostly employed.

Another and cheaper form of liquid orris oil is obtained by distilling orris-root with Cedar-wood oil, or by mixing this or some other suitable oil with the concrete. Naturally, orris oil made this way is much inferior to the true oil obtained from the concrete by removing the myristic acid.

It may be added that orris oil is used in making a number of high-class perfumes besides those having a Violet scent, the odour of orris blending well with such other odours as those of Mignonette, Lavender and Opoponax.

It may be mentioned, in conclusion, that, by extracting orris-root with a suitable volatile solvent, an oleo-resin can be obtained, which is also serviceable in perfumery for fixing such odours as those mentioned above. *H. S. Redgrove, B.Sc.*

THE GENUS PRIMULA.

(Continued from p. 429).

OFFICINALIS (Hill). The Cowslip.
(Vernales.)

The type of this well-known native plant produces a tuft or rosette of oval or oval-oblong, blunt leaves usually contracted into a short, winged stalk; margins toothed or scalloped; both surfaces more or less covered with minute, whitish hairs. Flower stem covered with minute down, three to six inches tall, bearing a many-flowered umbel of yellow blossoms. Corolla concave, three-eighths- to five-eighths-of-an-inch across; lobes rounded, notched; tube longer than the calyx. Flowers from March to May.

Grows in damp meadows and pastures over the greater part of central Europe.

Var. amplicata (Koch.). Calyx bell-shaped, flowers yellow; mountains of western Germany and Poland.

Var. ascapa (Gioran). Flower stem absent, stalks short; mountains of Verona, Italy.

Var. autumnalis (Pax). Flowers small, few, produced in the autumn; England.

Var. calycida (Schube.). Calyx cleft to the base; eastern Germany.

Var. uniflora (Hennings). Scape one-flowered; Holstein, Germany.

Var. macrocalyx (Bunge). Foliage covered with fine, greenish or greyish down; calyx broad at the base, lobes pointed, shortly triangular; flowers golden-yellow, five-eighths-of-an-inch to three-quarters-of-an-inch across; eastern Prussia, Urals, Caucasus, Turkey and northern Persia.

Var. alpina (Oktye). Very dwarf plant with an umbel of two to five sessile flowers; Kachetien.

Var. colchica (Pax). Foliage covered with grey down below; Russian Armenia and Songaria.

Var. virescens (Pax). Foliage green below; it has the same geographical range as the type.

Var. canescens (Opiz.). Leaves distinctly stalked, hoary below or nearly smooth; flowers half- to three-quarters-of-an-inch across; eastern and middle Europe.

Var. calvescens (Pax). Leaves green and rather smooth below; Austria and Hungary.

Var. cinerascens (Pax). Leaves hoary below; southern Europe.

Var. composita (Beck). Flowers in two superposed umbels; Austria.

Var. hardeggensis (Beck). Leaves densely covered with white down; Austria.

Var. Velenovskyi (Domin.). Leaves almost entire, nearly smooth; Bohemia.

Culture: The type, together with its numerous forms, may be grown in good, somewhat heavy loam in an open situation, abundantly supplied with water when in growth.

OPTATA (Farrer). Beck's P.
(Nivales.)

A handsome species, with foliage not fully developed at its flowering period. It has a short, stout rootstock which produces a tuft of broadly lance-shaped, or spathulate-oblong, blunt, bright emerald-green leaves about three inches long and five-eighths-of-an-inch wide, tapering to a rather short stalk dilated at the base; margins furnished with regular, saw-like teeth; both surfaces more or less white mealy; underside often with a conspicuous mealy margin. Flower stem four to five inches tall, green or slightly tinted with purple below, densely coated with white meal above and bearing one globular, or rarely two, superposed umbels but little separated, of violet-blue or lavender-blue blossoms with a darker eye. Corolla about one inch across, very slightly concave, with broadly oval or egg-shaped, notched or at times toothed lobes; tube cylindrical, membranous. Flowers in June and July.

Grows on the banks of brooks in limestone districts, at Siku, in Kansu, north-western China, at 12,000 to 14,000 feet above sea-level.

Culture: The requirements indicated are good, somewhat heavy, calcareous loam, and an open position well supplied with water when the plant is in growth.

ORBICULARIS (Hemsl.). Orbicular-flowered P.
(Nivales.)

A very beautiful species with a tuft of rather leathery, oblong-lance-shaped, nearly erect, blunt leaves two to six inches long, gradually tapering to a broadly-winged stalk somewhat dilated at the base; margins edged with minute teeth or nearly entire; upper surface more or less smooth, underside sparsely mealy. Flower stem erect, six to twelve inches tall, covered with yellow meal upwards and bearing a compact, rounded umbel of five to fifteen bright yellow, fragrant blossoms, on stalks about half-an-inch long. Corolla flat, about one inch across, divided into five somewhat overlapping, rounded, quite entire lobes; tube about as long as the calyx, cylindrical below, dilated upwards and contracted at the throat where there is an obscure ring. Introduced in 1905. (*Gard. Chron.*, June 23, 1906, Fig. 164, p. 403.)

Grows in damp, rich soil in open situations in central Szechuan.

Culture: As for P. nivalis. *A. W. Darnell.*

(*To be continued*).

HOME CORRESPONDENCE.

The Sweetest-scented Flower.—I quite agree with *R. Kemp* (p. 369) that this "opens up a tremendous field for argument," and I guess that after the argument in any large company the opinions on the subject will remain divided. A few more delightfully scented subjects may be mentioned, such as Pelargonium capitatum (Attar of Roses), P. vitifolium, P. tomentosum (Peppermint-scented), Mentha rotundifolia (Apple-scented Mint), M. Pulegium (Pennyroyal), Thymus vulgaris, T. citriodorus, Artemisia Abrotanum (Southernwood), Clove-scented Carnations, Hesperis matronalis (single or double Dame's Violet), Nicotiana affinis (Night-scented Tobacco), and Chrysanthemum Balsamita (Costmary). It will be noted that many of the above have a pungent, although pleasant odour that stimulate the senses on a warm day. I was tickled with the idea of the Vine in flower being a rival to Lily-of-the-Valley. To this I would suggest that a houseful of Peach trees being disbudded recalls the smell of Almonds. We read in some old books that Narcissus poeticus makes some people ill. I do not dislike the smell of the Night-scented Tobacco, but I have had to put two of them outside my door overnight! Some men have told me that Sweet Peas do not smell sweet. It is very doubtful if many people would care to live in a room with a plant or two of Lilium auratum in bloom. An avenue of Lime trees in full flower during the evening gives off a balmy odour that some would call stifling. Really we are not all constituted alike; each has some favourite flower or plant; and some have little or no sense of smell. I have been asked by a gardener if his Melons were "beginning to smell," showing that they were ripe. Under these various aspects of the question, could there be a consensus of opinion as to the sweetest-scented flower? *J. F.*

Difficulties of the Scottish Forestry Commissioners.—In your issue of June 8 (p. 429), I am taken to task by Sir John Stirling Maxwell, Bart., for a phrase I used in a paragraph under the above heading, to the effect that "the great difficulty is to make landowners' sentiments overcome their cupidity" in the matter of Scottish afforestation. Let me recount the little incident which led to my penning the phrase. Accompanied by the head forester, I was wandering the other day over the woodlands of a Scottish estate. In our ramble I was struck with the potentialities there were for afforestation work, and hazarded the remark to my companion —"Why not call in the aid of the Forestry Commissioners; they will be more than pleased to give advice and assistance in such matters." "Ah, well," replied the forester, "the Laird will not hear of it; he will not tolerate any dictation as to what will or will not be done on his estate." There, in a nutshell, was the inspiration of my phrase. Even Sir John himself admits there are landowners holding these views, but possibly I was too sweeping, or, shall I say, somewhat ambiguous in my assertion. I never for a moment meant to imply the phrase attached to the vast majority of Scottish landowners. Time and time again during past years I have written in these columns of the superb work the Scottish Forestry Commissioners have done and are doing for the afforestation of Scotland, and of the able assistance they are receiving from Scottish landowners. And in this respect let me note that Sir John himself, by pen and speech (broadcasting studio and lecture hall) has done yeoman service in the good work. It is a cause that lies very near to his heart, and may it long remain there. *Your Correspondent.*

Flowering Cherries.—In the issue of *The Gardeners' Chronicle* for June 8 (p. 420), your correspondent, *Prunyrus*, writing of the flowering Cherries, has occasion to remark that "the authorities Koidzumi, Miyoshi, Wilson, and, later, Ingram, differ in their classification." In so far as this refers to myself, the above statement is misleading. Having been schooled in ornithology—a science in which nomenclatorial priority is more strictly adhered to than in horticulture—I have made every effort to adopt the first used name when describing a species or variety. Since I have followed one or the other of these authors in almost every instance, it cannot be truthfully stated that I "differ" from my predecessors. The seeming divergence of the other writers is open to explanation. Possibly on account of Koidzumi's very inadequate descriptions, Miyoshi appears to have largely ignored his colleague when compiling his monograph of the Japanese Cherries. As Wilson's work appeared almost simultaneously with Miyoshi's, he naturally had no opportunity of referring to the Tokyo publication in his *Cherries of Japan*, but, later, he issued a supplement acknowledging the priority of a number of Miyoshi's names. With regard to the classification of the Japanese garden Cherries, I have already explained my reasons for following Miyoshi in keeping all the cultivated forms together under the one specific heading—Prunus serrulata. They have obviously been evolved from a number of species, but the parentage of many is too obscure to be satisfactorily recognised. Your correspondent states that Eva Gauntlett and Troiaya are "very similar" to Kanzan. All the plants that I have seen under these names have been indistinguishable from Kanzan, and their appellations appear to be only the invention of some ignorant nurseryman. I would also like to take this opportunity of pointing out that Hokusai and Ojochin are not the same plants. Uzu-Sakura and Hokusai may prove to be synonymous, but Ojochin is certainly a distinct variety. *Collingwood Ingram.*

Meconopsis Baileyi at Wisley.—Anyone who is fond of hardy flowers should visit the Royal Horticultural Gardens, Wisley, during the next few days, as a fine lot of Meconopsis Baileyi is now in flower and forms a sight that can only be seen in a few places in the United Kingdom the wonderful blue colour of this flower is becoming well-known, as specimens have been seen during recent years at Chelsea and other exhibitions, but to see it in masses, as it is at Wisley, is a sight that can never be forgotten. We hear and read criticisms of the work at Wisley but seldom find any of its good points mentioned, chiefly because, in my opinion, it does not advertise its work as it might justly do, and another reason, undoubtedly, is that much of the work done there is not easily understood by the general public. There are, however, very many interesting flowers to be seen at this time in addition to the above; and communications are much improved this year, as a service of express 'buses operates hourly from Oxford Circus. *W. H. Divers, V.M.H.*

[Mr. Divers overlooks the fact that we have published "Notes from Wisley" regularly, for several years.—Eds.]

SOCIETIES.

GRAND YORKSHIRE FLOWER SHOW AND GALA.

June 18, 19 and 20.—For the exhibition held at Knavesmire on these dates, the seventy-seventh occasion of the York Gala was favoured with brilliant weather. There was abundant sunshine and a pleasant breeze on the opening day, and a quite good attendance.

With the passing of the years and the variation of horticultural fashion, the character of the York Gala has altered considerably, while the personnel of the managing body has also changed. Specimen stove and greenhouse plants and giant Pelargoniums no longer provide the great feature of the show as they did in bygone days, when Bootham Park was the site of the exhibition.

Now-a-days hardy flowers are the main feature, and on this occasion they were well represented by alpine plants cunningly placed in rock gardens of varying size and importance, by bold groups of cut flowers from the herbaceous borders, and by such delightful florists' flowers as Lupins, Paeonies, Pyrethrums, Irises and Sweet Peas. Lupins are always a fine feature of the York show, and they were better than usual this year, for Messrs. Simpson and Son, Messrs. Harkness and Sons, and Messrs. G. Gibson and Co. all displayed generous spikes in a wide range of colours, the pink, fawn and chamois shades making a special appeal to the visitors.

Indoor plants were, however, not by any means forgotten, as evidenced by the numerous groups of graceful and brilliantly coloured foliage plants from stove and greenhouse, by the popular Begonias, Calceolarias, Orchids and Carnations, all of which were shown extensively and extremely well. Roses were much below the average, and for this failure the unkind season is responsible. Fruits, too, lacked the interest of old times, when McIndoe and others used to show fine collections of forced fruits, nevertheless, Messrs. T. Rivers and Son showed a grand lot of pot trees of Peaches, Nectarines, Citruses and Cherries, all loaded with fruits of the highest quality; this exhibit well deserved the Large Gold Medal awarded, plus the felicitations of the judges.

Floral designs were displayed in quantity, and the competition in this section of the show was larger and keener than usual.

The general arrangements of the show were admirably conceived and ably carried out, so that judging was finished well before the scheduled time, thus permitting all the awards to be placed in position before the public was admitted at 1 o'clock; indeed, the subscribers were admitted soon after noon. Mr. G. Y. Johnson makes an excellent Chairman and he is ably supported by the members of his Floral Committee, all of whom are strenuous workers, while John J. Hunt, Esq., as President, and Mr. P. Mennim, as Secretary, fulfil their respective duties to the general satisfaction of all concerned.

Housed in two large and broad marquees, the exhibition was very effective and the most colourful display yet seen at Knavesmire, and to this brilliant effect the trade groups made a very material contribution.

Groups.

Under this general heading come the rock gardens, arranged on a space twenty feet by fifteen feet, to be viewed all round. There were two competitors, and Mr. P. Gardner, Craven Nurseries, Addingham, secured the premier award of £15 with a pleasing display in which dwarf Conifers, Saxifrages, Oxalises, Violas and choice Primulas were grouped among and on the rocks, and in a moraine. The second prize fell to Mr. S. Pickering, Clifton, York, whose Water Lilies, Irises, alpine Asters and Violas were much admired.

The best ornamental rock garden, arranged on a space not exceeding thirty feet by twelve feet, was designed by Mr. P. Gardner, who used Azaleas, dwarf Conifers and Kalmias as a background for pleasing groups of Irises, Violas, Saxifrages and other attractive subjects; the second prize was won by Mr. S. Pickering, who employed coloured Maples and Pyruses as a background, and grouped Violas, Saxifrages and Primulas effectively; third, Messrs. A. Greenwood and Co., Wetherley.

Mr. T. M. Petch, Great Horton, was the only exhibitor in the class for a large group of miscellaneous plants; he was awarded the first prize for an exhibit of Palms, Codiaeums, Dracaenas, Hydrangeas, Fuchsias, Lantanas and Begonias. The foliage plants lacked that brightness of colour that adds so much to the beauty of an artistic grouping of plants.

In a smaller group class, the space allowed being sixteen feet by six feet, the competition was good, and Messrs. J. Cypher and Sons led with a bright display in which Liliums, Fuchsias, Thunias, Laelio-Cattleyas and Codiaeums were grouped effectively below a Fern-clad arch which was topped by a noble Tree Fern. The second prize was won by Mr. T. M. Petch.

In yet another group class, where cut flowers were permitted, Messrs. J. Cypher and Sons, Mr. T. M. Petch and the Clifton Fruit and Flower Growers' Co., secured the awards in the order given.

T. B. Bosvile, Esq. (gr. Mr. H. Bell), Gate Helmsley House, York, had the best group of herbaceous Calceolarias in a class that produced a fine effect. Major F. A. Robinson (gr. Mr. H. Lund), Dringhouses, and the Hon. G. N. de Yarburgh-Bateson (gr. Mr. W. Hobson), Deighton Grove, York, were successful exhibitors of tuberous Begonias, but in the leading class for these showy subjects, Messrs. Blackmore and Langdon won the premier award with a grand group of wonderful blooms in a great variety of colours. The hanging baskets of the varieties Fleur de Chrysantheme, Gladys and Mollie were very charming.

Orchids.

The seven classes devoted to Orchids provided a very attractive display. The exhibitors group their own plants together and not in the classes to which they belonged, and this does not make for ease or accuracy of judgment.

J. McCartney, Esq. (gr. Mr. C. F. Potts), Hey House, Bolton, won first prizes as follow: For three Orchids, with Odontoglossum Nerius, O. Crai and Cattleya gigas; for a single specimen Orchid, with Odontoglossum Buesh, carrying over fifty flowers; for six Orchids, with Vanda coerulea, Odontoglossum promerens, Laelio-Cattleya Canhamiana, etc.; for a specimen Orchid (amateur's), with Odontoglossum luteo-purpureum. He was also first for a dozen Orchids, his best plants being Brassia verrucosa, Dendrobium Dalhousieanum, Laelio-Cattleya Aphrodite, Cattleya Mossiae var. Wagneri, and Miltonias; second for a table of Orchids, and third for six Orchids.

Messrs. A. J. Keeling and Sons had the best table of Orchids, twelve feet by five feet, showing good Odontoglossums, Odontiodas, Vanda coerulea, Cypripedium Curtisii, Miltonias and Epidendrums. This firm also led for six Orchids, with Miltonia Sanderae, Cattleya Mossiae, Brassia verrucosa, Cypripedium Maudiae and Odontiodas; second, for a dozen Orchids, and second for a specimen Orchid, with a fine example of Anguloa Ruckeri var. sanguinea.

Messrs. James Cypher and Sons were awarded second prize for six Orchids, their set including a large Thunia Marshalliae, Laelio-Cattleya Dominiana, L.-C. San Juan and Cypripedium Lawrenceanum; and third prize for three Orchids.

Floral Designs.

Mr. F. H. Ward, York, led for a floral table centre with a design in blush Carnations, followed by the Clifton Fruit and Flower Growers' Co., with similar flowers; and Messrs. C. E. Simpson, who used orange Sweet Peas. Mr. F. H. Ward had the best hand-basket of flowers, showing a bold, rich design in yellow Richardias and golden Spanish Irises; second, Messrs. C. E. Simpson; and third, Messrs. Padgett and Watson.

The last-named firm led for a hand-basket of flowers (Orchids excluded), followed by Mr. W. C. Thorp and Mr. F. H. Ward, respectively. The best bowl of cut Roses was designed by Messrs. Backhouse Nurseries, Ltd., who used Madame Butterfly; Messrs C. E. Simpson and Mr. F. H. Ward secured the remaining awards. For a bowl of cut flowers, Messrs. Backhouse Nurseries, Ltd., Mr. F. H. Ward and Messrs. C. E. Simpson were placed as named; the first prize exhibit consisted entirely of art- coloured Gerberas.

Messrs C. E. Simpson led for a bride's bouquet, with a design of white Roses, Stephanotis, Gladioli and Lily-of-the-Valley; Messrs. Backhouse Nurseries, Ltd., were second, with Lily-of-the-Valley only; Messrs. Padgett and Watson, third.

Mr. F. H. Ward, Messrs. Backhouse Nurseries, Ltd., and Mr. W. C. Thorp secured the awards as given, for a bridesmaid's bouquet; while for a pair of hand-bouquets, the prize-winners were Mr. F. H. Ward, Mr. W. C. Thorp and Messrs. Padgett and Watson. For one hand-bouquet (open class), Mr. F. H. Ward, Messrs. Padgett and Watson and Mr. W. C. Thorp received awards.

Mr. F. H. Ward showed the best decorated table of fruits, Mr. W. C. Thorp coming second, and Messrs. C. E. Simpson, third.

Hardy Flowers.

The leading class in this division was for a collection of hardy perennials, including Liliums and other hardy bulbous plants or cut flowers, arranged in a natural manner, and to be viewed all round, on a space not exceeding 300 square feet. There were three competitors, and equal first prizes were awarded to Messrs. Bees, Ltd., and Messrs. Harkness and Sons. The former had a bold display of well-grown flowers of Irises, Poppies, Delphiniums, Pyrethrums, Lupins, Dianthuses and tall sheaves of Eremuri; theirs was a very artistic arrangement. Messrs. Harkness and Sons had splendidly grown Lupins in fine varieties, Pyrethrums, Poppies and other popular subjects, but their display was a trifle flat.

The points for this class were:—Quality of bloom, sixty; harmonious blending of colour, twenty; artistic arrangement and general effect, twenty; total one hundred. Messrs. Bees, Ltd., gained fifty, fifteen and twenty points, respectively, while Messrs. Harkness and Sons were awarded fifty-five, twenty and ten, the total being eighty-five in each case. Messrs. G. Longster and Sons were placed third.

In a smaller class for hardy flowers, Messrs. Bees, Ltd., Messrs. G. Gibson and Co. and Messrs. S. Gardner secured the awards in the order given.

Lupins were shown splendidly by Messrs. Harkness and Sons, who secured first prize, while their neighbours, Messrs. G. Gibson and Co., won second place; both showed a beautiful lot of flowers. Messrs. Bees, Ltd., led for a dozen bunches of hardy flowers, and in a similar class for amateurs, the prize-winners were Mr. W. Hutchinson, Mr. G. Millington and Mr. J. H. Jubb.

Mr. G. Prince was the most successful exhibitor of Roses and showed excellent sheaves and pillars of Irish Elegance, Pax, Emily Gray and La Rêve.

Awards to Non-competitive Displays.

Large Gold Medals.—To Messrs. T. H. Rivers and Sons, for fruit trees in pots (with congratulations from the judges); to Messrs. John Peed and Son, for stove and greenhouse plants: to Messrs. Dobbie and Co., for a delightful and brilliant exhibit of Sweet Peas; to Messrs. Allwood Brothers, for Carnations and hybrid Dianthuses, shown in grand style: to Messrs. Backhouse Nurseries, Ltd., for a fine rock garden; and to Messrs. Kent and Brydon, for an effective sunken garden.

Gold Medals.—To Messrs. E. Webb and Sons, for a large group of hardy and greenhouse annuals, etc.; Messrs. James Kelway and

Son, for Paeonies and Delphiniums; Messrs. C. Engelmann, Ltd., for perpetual-flowering Carnations; and to Messrs. W. H. Simpson and Son, for a particularly well arranged display of choice Lupins and Pyrethrums.

Silver-Gilt Medals.—To Messrs. R. H. Bath, Ltd., for Paeonies and Pyrethrums; Mr. H. N. Ellison, for Ferns; Messrs. G. Gibson and Co., for choice alpines and hardy Fuchsias; Messrs. Backhouse Nurseries, Ltd., for alpine plants; Messrs. Kent and Brydon, for alpines; Messrs. Maxwell and Beale, for alpine plants; Mr. A. Winn, for hardy flowers; Messrs. C. Bloom and Son, for a rock garden; and to Messrs. Maurice Prichard and Son, for alpines.

Silver Medals.—To Messrs. Toogood and Sons, for Irises; Mr. C. Holt, for hardy flowers; Messrs. Bakers, for hardy flowers; Messrs. Barr and Sons, for hardy flowers; the Hon. Geoffrey Howard (gr. Mr. E. Clements), Castle Howard, for Campanulas; Mr. G. W. Miller, for hardy flowers; Mr. J. Winn, for Violas; Mr. E. Clegg, for Violas and Pansies; Messrs. B. Ladhams, Ltd., for hardy flowers; Mr. F. Rich, for hardy flowers; Messrs. James Cypher, and Sons, for Fuchsias; Messrs. Blackmore and Langdon, for Delphiniums; Messrs. Walshaw and Sons, for Ivy-leaved Pelargoniums; and to Mr. R. V. Roger, for hardy flowers.

The Gardeners' Chronicle Medal.—To the Hon. Geoffrey Howard (gr. Mr. E. Clements), Castle Howard, Yorkshire, for a group of superbly grown plants of Cup-and-Saucer Campanulas.

Awards of Merit.

Paeony Kelway's Remembrance and *Paeony Lord Kitchener*, from Messrs. James Kelway and Son.

Hybrid Dianthus Sweet Wivelsfield.—From Messrs. Allwood Bros.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall on Monday, June 10, Mr. T. R. Butler presiding. Three new members were elected. Four members withdrew interest from their deposit accounts, which amounted to £18 7s. 0d., and one member over the age of seventy years withdrew £54 5s. 8d. from his deposit account. The sum of £99 18s. 3d. was passed for payment to the nominees of two deceased members. The sick-pay for the month on the Ordinary side came to £113 14s. 6d., and in the State section to £93 7s. 6d. The sum of £13 3s. 10d. was allowed in grants from the State section to six insured members for dental treatment, and twelve other cases were considered.

SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE.

On account of the backwardness of the season, the spring exhibition of the French National Horticultural Society, which took place at Cours-la-Reine, in Paris, from May 24 to June 2, did not provide quite its usual wealth of blossom and colour; but the general arrangement left nothing to be desired, and the show presented a most attractive appearance.

The firm of MM. Moser, of Versailles, showed a typical modern garden, of which the centre feature was two parallel lines of water, the margins decorated with coloured pottery receptacles filled with Tropaeolums. In the background was a gaily coloured pergola clad with climbing Roses, and which served to frame an immense, curved mirror reflecting the central portion of the garden. The paths were marked out in round, white tiles laid on the turf. Dwarf Polyantha Roses in various colours, in which red and orange shades predominated, formed an effective contrast to blue Hydrangeas, the whole effect being bright and cheerful.

The Paris Florists' Syndicate had a collective exhibit, consisting of five "salons" intended to represent the part played by flowers at various stages in life, from birth to death. The first salon was a symphony in white; maturity was represented by rich tones of yellow and gold; decorations for the silver and golden-wedding-anniversaries followed; and finally, the wreaths and floral decorations for a funeral. This last portion of the exhibit was intended as a protest against the modern tendency to proscribe the use of flowers at funerals, as at the funeral of the late Marshal Foch, which constitutes a serious menace to the florists' trade.

The firm of MM. Vilmorin-Andrieux, although not exhibiting for competition, had a large group in the centre of the tent. The group was a varied one, consisting of annual and biennial hardy plants, arranged with a view to presenting a light and brilliantly coloured effect; the form was a large rectangle with a hollow centre, the whole tastefully displayed.

The finest garden Irises were not yet in flower at the period of the exhibition, and although the weather was warm, they were not out until some days later. However, Messrs. Cayeux et Le Clerc, of Paris, had a very fine group of modern varieties, including Fédora, yellow; Madame de Sevigné, one of the finest of the plicata section; Germaine Perthius, a large, purple-violet variety; Jean Chevreau, creamy-yellow; Shekinah, citron-yellow; Fidelio, blue, with clear violet falls; Marc Aureau, lavender and violet; and Lohengrin. They also showed some very fine new varieties, which were awarded Certificates of Merit, namely Vert Galant, Durandal, Farandole, Nemo, Président Pilkington, Cassandre and Evolution.

The prize for the finest Iris of the year (not yet in commerce) was awarded to the variety Vert Galant, which also formed one of the trio (Durandal and Evolution being the other two) to gain the award for the three finest varieties, all being raised by the firm of Cayeux et Le Clerc.

MM. Vilmorin-Andrieux had also a large group of Irises artistically displayed in sheaves, set in cane baskets. At the opening of the exhibition most of the varieties shown belonged to the so-called "intermediate" section—Dorothée, Dauphin, Helgé, Diamond, etc.—which would, in a normal season, have been over. In addition, there were some very fine new varieties with large flowers, including Debussy, very pale pink; Andromede, smoked violet; Bellatrix, a very fine glossy violet, washed with yellow; Fra Angelico, smoked nut-yellow; Van Dyck, violet, with smoked falls; Velouté, velvety black-violet; Alliés, reddish, shading to brown; Mignard, pale mauve-pink, etc. Several of these received Certificates of Merit.

MM. Defresne, of Vitry; MM. Lévèque, of the same town; M. Nonin, of Chatillon-sous-Bagneux; and M. Royer, of Versailles, all showed Roses. Hothouse plants were exhibited by the Versailles Horticultural College, and Cacti by MM. Thiebaut, of Paris. Alpine and hardy plants formed the group sent by MM. Laumonnier-Ferard, of Paris, while M. Coutis, of Garche, and M. Lievre, of Vitry, showed scenes respresenting modern gardens, with pergolas and porticos. Rhododendrons were exhibited by M. Croux, of Chatenay; trees, shrubs and Conifers by M. Lecolier, of La Celle-St.-Cloud, M. Thuilleaux, also of La Celle-St.-Cloud, and M. Martin, of Louveciennes. A magnificent collection of vegetables was exhibited by MM. Vilmorin-Andrieux et Cie.

The Grand Prix d'Honneur of the President of the Republic was awarded to M. Nomblot-Bruneau, for a very fine collection of pot fruit trees, trained in various forms and covered with fruits, including Gooseberries, Peaches and Apples. The second Grand Prix d'Honneur was won by M. Defresne, of Vitry, for his collection of Roses.

There were no Orchids whatsoever.

M. Royer, of Versailles, had a fine display of Roses of the dwarf Polyantha section, comprising new varieties of Dutch raising, notably the following seedlings of Dr. Ruyter and Kesbergen:—Perfection, bright red; Rudy Korte, carmine-red; Kersbergen, fiery red; Gloria Mundi, vermilion-red; Paul Crampel, orange; Dainty, pink; and Madame Huding, orange.

Among the exhibits of MM. Cayeux was a charming little display of Cineraria Naine Idéale (Ideal Dwarf), the plants measuring only twenty centimetres in height.

The *Revue Horticole*, of Paris, was celebrating its centenary year by a very fine exhibit—a pergola furnished with climbing Roses. Two charming young girls, in appropriate costumes, symbolised respectively the years 1829 and 1929.

Certificated Irises.

The following were shown by MM. Cayeux et Le Clerc:—*Vert Galant*, large flower, coppery-red, deep garnet-red falls. *Durandal*, Pallida section, coppery-reddish-purple and garnet-red. *Farandole*, lilac-pink, falls purplish-red. *Nemo*, self-coloured blue. *President Pilkington*, very deep indigo colour. *Cassandre*, standards smoky grey, falls garnet-red. *Evolution*, standards golden-yellow, falls garnet-red.

The following were shown by MM. Vilmorin-Andrieux et Cie:—*Nicée*, deep lilac, standards slightly smoked. *Phocée*, lilac-mauve, falls white. *Judée*, deep lilac-pink. *Egée*, large variegated flowers, standards lightly smoked. *Colisée*, reddish-violet, falls a deeper colour. *A.M.*

ROYAL CALEDONIAN HORTICULTURAL.

At the monthly meeting, held at Edinburgh, on June 4, Mr. R. L. Scarlett, who presided in the absence of the President, congratulated Mr. Jeffrey, Director of the City Parks, on the excellent floral display in Princes Street Gardens on the occasion of the recent visit of the Duke and Duchess of York.

The admission of twenty-nine new members was announced by the Secretary, and thereafter Dr. Balfour Gourlay, Cambridge, delivered a lecture on "A Botanical Trip to Chile," which he made in 1927, along with Mr. Clarence Elliott. Their journeyings were illustrated by a series of lantern slides, several of which testified to the wealth of plant life in a part of the country where rain seldom falls.

In the competitive classes, first prizes were awarded to Mr. G. Godsmark, Luffness Gardens, Aberlady, for a vase of Carnations, and to Mr. J. A. Sword, Cramond, for two Lettuces.

Exhibits were particularly numerous and of a high standard of quality. The City Park Department staged a lovely group of the Lupin Pink Pearl, together with Hydrangea Parsival; and Messrs. Dobbie and Co. were represented by a collection of Cottage and Darwin Tulips. Silver Medals were awarded to both exhibits. The Edinburgh firm also exhibited interesting examples of Roses, Pelargoniums, Fuchsias and Allwoodii Pinks grown in glass jars containing sand, gravel and water. Mr. Robert Fife explained that the American florists claimed they could flower certain plants for market in six weeks by keeping them in water, and the exhibits were the result of an experiment to throw light on the subject, sand and gravel being used to keep the plants in position. The water was never changed, fresh water being added from time to time, together with certain solutions containing soda, potash, iron, lime and magnesia. The Roses, which were of the Shot Silk variety, were lifted in March, and one of the plants had produced a flower. All the plants did better in sand than in gravel, and as he was continuing the experiments, he hoped to show better results next year.

Other exhibits included a new Strawberry named Early Strathearn; specimens of Balfour's Late Broccoli measuring twenty-five inches in circumference, and the produce of one root of Dawes' Champion Rhubarb, weighing 23¾ lbs., all of which were grown by Mr. J. W. Scarlett, Inveresk. A display of alpine plants by Mr. F. Glass, Murrayfield, received a Cultural Certificate, and two vases of Tulips (Princess Elizabeth and Bartigon) staged by Mr. A. C. Bell, were awarded a vote of thanks, an acknowledgment also accorded to Mr. Scarlett.

SALISBURY GARDENERS'.

ON Monday evening, June 3, at the kind invitation of Mr. and Mrs. S. R. Christie-Miller, over one hundred members and friends of the Salisbury Gardeners' Society, accompanied by Mr. A. C. Jonas, Vice-President; Mr. S. W. Tucker, Chairman, and Mr. W. F. Gullick, Secretary, spent a delightful time in the grounds and gardens of Clarendon Park. The name of Christie-Miller is so closely connected with horticulture that rarities were anticipated, but even the most sanguine of the party hardly expected to view so great a variety of trees, shrubs and plants amid such a glorious setting.

Mr. and Mrs. Christie-Miller, with their gardener, Mr. G. Perryman, met the party on arrival, and immediately conducted it on a tour of inspection, through semi-woodland along winding pathways where masses of Rhododendrons, and bold plantings of Viburnum tomentosum and its variety Mariesii, with occasional rich red Maples, were to be seen, to the Dell and Wild Garden, which less than twelve months since were banks of Nettles, and are now a veritable paradise. Cunning waterways and miniature lakes, banked with thousands of Primula japonica, P. pulverulenta and P. Bulleyana, with here and there masses of P. Aileen Aroon, P. helodoxa and P. Bartley's Pink, provided a feast of colour. Here, too, were hundreds of Iris laevigata, casting their beautiful reflections in the clear water, while high up on the banks, grand specimens of Cytisus Donard's Seedling, Diervilla Eva Rathke, just coming into flower, and arching sprays of Tamarix and Berberis, combined with a setting ordained by nature, made a picture which will live in the memory of those present.

Reluctantly leaving this enchanting spot, attention was drawn to splashes of colour in the distance, which were found, on nearer approach, to be large specimen Rhododendrons—Corona, Mrs. Stirling, Goldsworth Yellow, Doncaster, etc.—and a number of species, including a fine plant of R. Falconeri, all in beautiful condition.

Proceeding across the terrace front, still gay with Wallflowers, to a wide border of choice shrubs, fine specimens of Rhododendron cinnabarinum and R. Loderi were noted, just passing out of flower; also a grand plant of Azalea coccinea var. speciosa. This plant, backed by a giant Rhododendron ponticum, produced a wonderful effect, startling yet beautiful. From here the party passed to the Iris garden, which, although less than twelve months old, was gay with many choice varieties. Beautiful heads of Majestic, Aphrodite and Souvenir de Madame Gaudichau, were in splendid form. Other outstanding varieties were Evadne, Dream, Alcazar, Lord of June, and a fine group of the maroon and yellow Iris King.

The herbaceous borders, a little later, undoubtedly look resplendent with their bold plantings of Delphiniums, Papavers, Lupins, etc. The kitchen garden is by no means a prominent feature at Clarendon Park, but even here, under the skilful management of Mr. Perryman, who undoubtedly believes in good cultivation, some excellent crops were noticed.

Judging from the healthy batch of seedling Lilies in the frames, including a number of Lilium centifolium, a few years hence the woodland walks of Clarendon Park will not only contain choice Rhododendrons, but groups of Lilies also. Certainly a more delightful spot for growing them it would be impossible to find.

Effects of the damage by frost were apparent in many choice shrubs. A giant Magnolia salicifolia (probably one of the finest in England), is completely destroyed, while one large Abutilon vitifolium has been killed, and another specimen is just breaking at the base. Pittosporums also have suffered, but with a gorgeous display by so many beautiful shrubs and plants, these losses are hardly noticeable to the visitor.

The thanks of the Society were conveyed to Mr. and Mrs. Christie-Miller and their gardener, Mr. Perryman, through Mr. A. C. Jonas and Mr. W. F. Gullick, for a really most delightful evening.

Obituary.

Carl Kirch.—We regret to record the death, at the end of last month, of Mr. C. Kirch. Starting with a large rock garden and herbaceous borders at Albemarle Road, Beckenham, Mr. Kirch added extensively to his garden during recent years, and at the time of his death held one of the largest stocks of rare alpine plants in the country; these were admirably grown in a large, double-spanned house and in a long range of frames. His present gardener, Mr. Harris, was previously in charge of the rock garden at Wisley, to which post his late gardener has succeeded. Mr. Kirch was a frequent and successful exhibitor at the Royal Horticultural Society's shows. He was engaged in business in the Central Meat Market, where he was wont to collect large sums for St. Bartholomew's Hospital. A man with a great heart, his last act was to plan a set of rooms at this Hospital where patients' friends could spend the night.

ANSWERS TO CORRESPONDENTS.

ANTS IN PEACH HOUSE.—*W. F.* Ants are very troublesome creatures in fruit houses, as, apart from feeding on the ripe fruits, they spread about such pests as mealy-bug or aphides that may be present. Boiling water, where it can be used, is a sure remedy. Ballikiurain Ant Destroyer, a poison, is also a very effective remedy. Kamforite or a little bisulphide of carbon placed well down into their runs will quickly remove or destroy them.

CARNATIONS DISEASED.—*J. C.* The Carnation foliage is affected with bacteriosis following an attack by thrips, the dead bodies of several being found within the growing points. The weak and deformed shoots show that the plants have received a decided check in growth. Faulty watering and an excessive amount of overhead syringing will produce similar malformation in many varieties. The plants should receive a stimulating fertiliser and this, together with careful watering, will allow the plants to grow away and produce normal growths.

LADS' WAGES.—*V. K.* As a rule, well-developed boys, fourteen to fifteen years of age, receive 15s. per week; a few gardeners start these boys at 12s. per week and increase the amount every three or six months, according to ability. Afterwards agricultural wages, as fixed, are generally paid in large private gardens, these varying according to the county or district.

LEASE OF GARDEN.—*J. J. M.* Without seeing the documents it is impossible to give a definite reply, but if the lease that was granted to your brother-in-law has been assigned to you, the landlords can enforce the covenants as to repairing and painting against you as assignee and against your brother-in-law as the original lessee.

NAMES OF PLANTS.—*E. T. M.* Dicentra eximia; obtainable from any nurseryman who deals in hardy herbaceous plants.—*A. S.* 1, Prunus Padus; 2, Allium giganteum; 3, Cotoneaster horizontalis; 4, Rosa Hugonis; 5, R. sericea; 6, Saxifraga Sibthorpii; 7, S. trifurcata hybrid; 8, S. trifurcata × S. hypnoides; 9, S. hypnoides (southern form); 10, S. hypnoides; 11, S. Hostii var. altissima; 12, Asplenium trichomanes; 13, Akebia quinata; 14, Polgala vulgaris; 15, Epimedium rubrum.—*G.* 1, Pyracantha coccinea; 2, probably a Eupatorium, but please send a better specimen; 3, Deutzia gracilis; 4, Lonicera Xylosteum; 5, impossible to name, specimen too scrappy.—*J. C.* A Poplar, possibly Populus berolinensis, but impossible to be certain from a single leaf.—*H. P.* Cryptomeria japonica.—*S. J.* Prunus Padus.—*A. M.* Macleania insignis.—*J. S.* Chrysogonum virginianum.—*Muntham.* Rosa spinosissima var. altaica, a Siberian Rose sold in nurseries as Rosa altaica.—*W. A. H.* Paeonia tenuifolia var. flore plena.—*A. P.* 1, Not recognised, send when in flower; 2, Brodiaea (Tritelia) uniflora; 3, Phillyrea media; 4, Teucrium fruticans; 5, Erica mediterranea; 6, Prunus persica var. flore albo pleno; 7, Prunus Sieboldii (syn. P. Watererii); 8, Spiraea prunifolia var. flore pleno.

PEACH TREES NEWLY PLANTED.—*B. M.* Young Peach trees, three years old, planted last October, should have been well watered in after planting to settle the soil well down among the roots. This would have carried them through the winter months, as an excess of water when the trees are at comparative rest is almost as bad as the lack of it when they are in active growth. At no time during the growing season should Peach trees feel the want of water, and if the drainage and compost is all right they will need water at least every three weeks at this season of the year. A mulching of horse manure or light litter will help the trees, and will be found a great protection to the surface roots. Very few, if any, fruits should be allowed on the trees the first year. Every effort should be made by syringing the trees twice daily on bright days to encourage growth, and so build up good trees for succeeding seasons' crops.

STEM EELWORM IN ONIONS.—*G. B.* Your Onions are heavily infested with the stem eelworm, Tylenchus dipsaci. The autumn and early-sown plants are also attacked by the fungus Mucor subtilissimus. These may be saved by the avoidance of nitrogenous manures, *e.g.*, nitrate of soda, etc., which tend to produce sappy growth. Dress the plants with sulphate of potash. The small plants cannot be saved, and should be pulled up and burnt. Great care should be taken to prevent the spread of the eelworms by garden tools and the boots of workers from the infected land. Refrain from planting Onions on the infected land for a period of at least three years.

TOMATO PLANTS DISEASED.—*F. W. R.* Your Tomato plants are affected with one of the Phytophthora foot-rot fungi. Destroy badly infected plants and water the remainder with freshly-made Cheshunt compound. The fruits show signs of buckeye disease, due either to the same fungus or to a closely allied species which attacks the fruits on the lower trusses. The plants should be mulched with straw to prevent the infected soil from splashing on to the fruits. The soil from the borders should be steam sterilised before being used again for Tomatos. Water from dirty tanks is often infected with the spores of the fungus.

TOMATO FRUITS DISEASED.—*F. Y., C. M. F.,* and *J. W.* The Tomato fruits are suffering from blossom-end-rot, a disease induced by an insufficient amount of water in the soil over a number of days. It has been shown that soil moisture affects the development of the disease. Nitrogenous manures should be applied, using nitrate of soda rather than sulphate of ammonia.

VIOLA FOOT-ROT.—*H. G. M.* The Viola plants are attacked by a species of Phytophthora which causes "foot-rot" in many plants. The infected plants should be removed from the bed and burnt and the ground watered with Cheshunt compound. It is advisable to water round the remaining healthy plants with the same compound. The millipedes may be destroyed by applying naphthalene at the rate of three to four ounces to the square yard around the plants. The ground should be lightly forked over and the material distributed and watered in.

REMARKS.—Single Pyrethrums appear to have had a very short season, and the small quantities still available are very poor in quality. Irises are still arriving in large quantities, the most reliable blooms being from home growers. Gypsophila elegans supplies are the best received this season, and are more than sufficient for present requirements. Other subjects which have shown a considerable increase are white Pink Mrs. Sinkins, Cornflowers, Delphiniums, Iceland Poppies, Marigolds, Nigella (blue), and the small-flowered Gladioli, Gandavensis varieties are increasing daily in quantity and now embrace fine shades of pink, scarlet and white. Sweet Peas are arriving in fine condition, and all the best grades are soon cleared. Lilium longiflorum is again on the down grade, while L. lancifolium is very scarce. Carnations and Roses have been in excellent demand during the past week, and many orders arriving late could not be met with reliable blooms. Supplies of Coreopsis and Gaillardias are increasing daily, also of some very fine varieties of Daisies. The most recent arrivals are white and mauve Sweet Sultans, Scabiosa caucasica (blue), Paeonies from home-growers, and pink and blue Erigerons.

REMARKS.—The fine weather is helping to prolong the period of activity now being experienced in Covent Garden. All choice fruits, such as Grapes, Peaches, Nectarines, Strawberries, Melons and Figs, sell freely owing to the demands of Ascot and other functions of the London season. A few punnets of forced Raspberries are a novelty and sell well at high prices. Strawberries are increasing in quantity each day, but so far they have not been sufficiently plentiful to affect sales of other fruits as they usually do. Australasian Apples are a firmer trade at slightly higher prices. Some very good Cherries are now available from Italy and sell well. The first English Cherries are also on the market, but these early fruits do not compare favourably with those from Italy. English Gooseberries sell with difficulty even at low rates, prices being poor for even the best fruits, while small berries are almost unsaleable. Dutch competition in this section is keen. Mushrooms have been through a lean period; quantities are heavy and prices low, but at the time of writing, there is some slight improvement owing to a slackening in the supply. English Tomatos have been a steady trade, but there is now an easier tendency, although the price level is still good. The trade in Cucumbers is helped by the fine weather, and this department is active. French Beans sell with rather less freedom than previously, and at lower prices, the largely increased supplies of outdoor Peas being responsible for this. New Potatos sell fairly well at lower prices. Salads are plentiful and cheap, and green vegetable supplies are ample for requirements.

GLASGOW.

Cut flowers were again very plentiful last week, especially Irises and Pyrethrums, and although prices moved irregularly, the changes were small and unimportant. The last of the Darwin Tulips were poor in quality and only realised from 3d. to 4d. for 12's, and double white Narcissi were worth from 3d. to 5d. Sweet Peas varied in price from 3d. to 5d. for short stem bunches, and 9d. to 1s. 3d. for well grown flowers; Roses sold at 3s. to 4s. 6d. per dozen; Carnations, 2s. to 4s.; Irises, 2½d. to 4d. (6's); and 5d. to 6d. for specials; Anemones, 3d. to 6d.; Gladiolus Prince of Wales, 2s. to 2s. 6d. (6's); The Bride, 10d. to 1s. 2d. per dozen; Maiden's Blush and Blushing Bride, 1s. to 1s. 4d.; Poppies, 6d. per bunch; Gypsophila, 2d. to 4½d.; Lily-of-the-Valley (indoor), 1s. 6d. to 1s. 9d.; Lilium longiflorum, 3s. to 4s.; Nigella, 1s.; Lupins, 3d. to 4d.; Asparagus (medium), 1s. 3d.; trails, 2s. to 3s.

The first consignment of Southampton Strawberries reached the market on Saturday, and was sold at 2s. per lb., while Cheddar Strawberries fluctuated between 1s. 6d. and 2s. Home-grown Grapes were cheaper at 2s. 9d. per lb.; Melons, 4s. to 7s. each; Scotch Peaches, 1s. to 1s. 6d.; Apricots, 14s. per crate; Gooseberries, 3d. to 5d. per lb.; Cherries, 1s.; and Gages, 15s. to 22s. per box. Grape Fruits, which sold at 28s. to 32s. per case in the previous week, advanced to 30s. to 40s.

Tomato prices remained steady, Scotch selling at 10d. 1s. 2d. per lb., and Guernsey, 9d. to 10d. Locally-grown Lettuces were worth from 2s. 6d. to 3s. per dozen; Cucumbers, 5s. to 7s. 6d.; Radishes, 3s. 6d.; Asparagus, 3s. to 4s. 6d. per bunch; Syboes, 4d. to 5d.; Carrots and Turnips, 10d. to 1s. 1d.; and Mushrooms, 2s. per lb.

WEATHER IN MAY.

Unsettled conditions prevailed during the earlier half of the month of May, showers—mostly beneficial to all vegetation—occurring almost every day, while a few substantial falls of rain were measured. The sunshine records the while, were rather poor, and the weather was not warm; southerly winds were general. During the later half of May all was different, persistent, light, easterly winds producing numerous almost cloudless, but rather hazy, days, with considerable amounts of sunshine and high maximum temperatures, but practically no rainfall. For the complete month, the mean temperature was 52·7°, or 1·6° above the average. There were 245 hours, of sunshine—a surplus of 36 hours. Rain fell on 13 days, and the total was 1·96 inch, or only 0·25 inch below normal. No thunder occurred; two slight ground frosts, and one brief and very moderate gale, constituted all the occasional phenomena. *Joseph Baxendell, The Fernley Observatory, Southport.*

SCHEDULES RECEIVED.

HIGHFIELDS AND DISTRICT GARDENING SOCIETY, Leicester.—Twelfth Annual Show, at St. Philip's Parish Hall, Evington Road, Leicester, on Saturday, August 17, 1929.—Secretary, Mr. W. H. H. Green, 10, Ashbourne Street, Leicester.

THE ROUNDHAY (LEEDS) HORTICULTURAL SOCIETY.—Annual Floral Exhibition, in Roundhay Park (Sports Arena) Leeds, on Tuesday and Wednesday, July 16 and 17, 1929.—Secretary, Mr. William F. Kitchingman (Room No. 12), 8, York Place, Leeds.

ST. PETER'S, NORBITON.—Seventeenth Annual Flower and Industrial Show, on the Vicarage Lawn, on Saturday, June 29, 1929.—Secretary, Mr. H. Thomas, Warren Point, Gloucester Road, Kingston Hill.

HULL AND EAST RIDING ROSE SOCIETY.—Third Annual Exhibition, in the Central Hall and Annexe, Pryme Street, Hull, on Thursday, July 18, 1929.—Secretary, Mr. W. F. Proctor, 38, Tavistock Street, Hull.

GARDENING APPOINTMENT.

Mr. G. Warner, for the past six-and-a-half-years Head Gardener to the late Sir JOHN BRUNNER, Bart., of Sandiway House, Northwich, Cheshire, as Head Gardener to R. H. GILLESPIE, Esq., Dene Place, West Horsley, Surrey. [Thanks for 2s. for R.G.O.F. Box.—EDS.].

A TOO CROWDED ADVERTISEMENT WEARIES THE EYE; ONE WORD QUICKLY PERCEIVED IS BETTER THAN TWO NOT PERCEIVED AT ALL.

Sunshine and Yield of Crops.

As everybody knows, the chemical constructiveness of plants depends on sunshine. In the absence of light the green plant belies its name, remains colourless and, unable to make its sugars and other foods, dies of starvation. On the other hand, every gardener in this time of drought, knows that plants often find sunshine inopportune. They may have too much of a good thing, as witness in this spring and early summer how blossom has hastened away and how growth has been arrested. Evidently, therefore, if anyone were to ask what is the influence of sunshine on the yield of crops, a wise gardener, at all events, would hesitate before giving a confident answer. He would point out that the effect of sunshine depends on many other factors, the nature of the soil and the moisture of air and of ground. If all these other factors are sufficient, then bright sunshine will bring bumper crops; but if one or other be lacking the same bright sunshine may bring nothing but trouble. It is one of the disabilities under which gardeners labour that they cannot control the weather, and it is therefore a not infrequent cause of disappointment, for spells of sunshine, delightful to the human, are, or may be, disastrous to the vegetable. For this reason, if for no other, every gardener likes to have the control of some "glass"; for the possession of a glasshouse confers on him a large measure of independence of weather vagaries. Yet, despite numerous experiments, no certain and satisfactory means of supplying deficiencies of sunlight have as yet been devised. Temperature, both of soil and air, fertility of soil, movement of air—all these the possessor of a glasshouse may control. He may also mitigate the beams of sunshine, but until now he has not been able to make good their deficiencies. Yet, from the observations and experiments carried out at the Experimental and Research Station, Cheshunt, and reported* by Dr. W. F. Bewley, it would seem that there is a means, and that a curious one, of helping the plant to make the most of sunlight in periods when sunshine is defective. Dr. Bewley first ascertained that, as might be expected, Tomatos grown in this country under glass give the largest yields in years of brighter sunshine. The *annus mirabilis* of recent times, 1921, was, as most of us remember with regret, a year of bright sunshine. It was also the year of largest Tomato yields of any between 1917 and 1927. These records are the more trustworthy in that they apply to houses in two distinct districts, Cheshunt and East Grinstead. In the case of this crop it is the sunshine which occurs between April and August that counts in increasing crop production; before that it is of less importance. Now, as to the means of supplementing sunshine. From fertiliser trials carried out over a period of ten years, 1917-1927, and fully recorded by Dr. Bewley, it is quite evident that the addition of potash to the fertiliser applied to the plants enables the Tomato to yield better in years of poor sunshine than it otherwise would. Conversely, when the sunshine is plentiful the fertiliser which gives the best results is one which contains less potash and more nitrogen. Thus, a judicious balancing of these two fertilisers helps the grower to make the best of sunshine and of clouds. It would seem that these interesting observations might be usefully applied by gardeners who grow plants under glass, not only with respect to summer crops, but also with respect to those which mature during the shorter days of the year.

Essex Gardens Open to the Public in July.—The following Gardens in Essex will be open to the public in aid of the Essex County Nursing Association and other local nursing services during July, the charge of admission to each being 1s.: July 1, Hedingham Castle Keep (Mrs. Majendie); Moyns Park, Halstead (J. P. Walker, Esq.); July 3, Hill Hall, Epping (Lady Hudson); July 6, Faulkbourne Hall, Witham (Mrs. C. Parker); Braxted Park, Witham (Mrs. Boulton); July 13, Rookwoods, Sible Hedingham (Miss Sparrow); Dynes Hall, Halstead (Mrs. Gosling); July 17, Langleys, Great Waltham (Mrs. Tufnell); July 20, Terling Place, Chelmsford (Rt. Hon. Lord Rayleigh); Boreham, Chelmsford (Mrs. C. Pilkington); July 28, Short Grove Hall, Newport (Captain F. J. O. Montagu).

Scottish Institute for Soil Research.—At a meeting of the Governors of the North of Scotland College of Agriculture, held at Aberdeen on Thursday, June 20, the Research Committee reported that a communication had been received from the Department of Agriculture for Scotland forwarding the memorandum of the scheme for the establishment of an institute for soil research, to be called the Macaulay Research Institute, at Aberdeen, to be administered by an *ad hoc* Committee of eleven members, of whom three were to be nominated by the University of Aberdeen, three by the North of Scotland College of Agriculture, one by the Edinburgh and East of Scotland College, one by the West of Scotland Agricultural College, and three by the Department of Agriculture for Scotland, and that Dr. W. G. Ogg, M.A., B.Sc., is to be appointed Director of the Institute. Mr. T. B. Macaulay, President of the Sun Life Assurance Company of Canada, who is at present on a visit to Scotland, has agreed to undertake the whole cost of founding the Institute, not to exceed £10,000, subject to arrangements being made for meeting the cost of maintenance out of the public funds. One of the primary duties of the Institute is to investigate problems relating to peaty and moorland soils, but research in connection with other classes of soils is not to be precluded. The report was unanimously approved.

Imperial Botanical Conference, 1930.—At a meeting of the Executive Committee of the Imperial Botanical Conference (1924) held in London on January 18 last, it was decided to arrange a short Imperial Botanical Conference to be held immediately before the International Botanical Congress in 1930. The Imperial Botanical Conference, which it is intended should last only one day, will meet in London on Friday, August 15, 1930, at the Imperial College of Science and Technology, South Kensington, S.W.7. The agenda before the Conference will be purely of a business nature. The proposal to hold a further Imperial Botanical Conference in 1935, on lines similar to that held in 1924, will be discussed, and, if necessary, the appropriate organisation for convening the Conference will be arranged. Reports of the Committees which have dealt with the resolutions of the 1924 Conference will be received. Any other business which it is desired to lay before the Conference should be communicated to the Hon. Secretary of the Executive Committee, Professor W. Brown, Imperial College of Science and Technology, South Kensington, S.W.7, in due course.

Rose Show at the Hague.—From July 19 to 21, a Rose Show will be held in the Zoological Gardens at The Hague, Holland. The motto adopted will be *Nos Jugunt Rosae*, and it is expected that the event will be a very popular one, the Dutch people being devoted to flowers and especially to the Rose. Roses grow well in Holland, in spite of the loose and sandy nature of the soil, and many are exported to this country, where, however, they are not always successful, mainly owing to the great difference in the soil conditions between the two countries.

Sydney Botanic Garden Staff.—As the result of a ministerial visit to the Botanic Gardens in Sydney, New South Wales, last year, several employees at the Garden were either dismissed or de-rated (reports *Red Tape*, the organ of the N.S.W. Public Service Association). As both permanent and temporary men, of long service and with honorable records, were stated to be among those who received notice of dismissal, a member of the Association's Committee was deputed to make enquiries and prepare a report. The report was presented in December, 1928, and stated, among other things, that no opportunity had been given to the employees concerned to be heard in their own behalf, and no proper enquiry had been held by the Public Service Board. A deputation from the men was subsequently received by the Board, and it was hoped that a properly constituted enquiry would be granted.

Centenary Number of "La Revue Horticole."—Our French contemporary, *La Revue Horticole*, of Paris, is celebrating the centenary year of its foundation, and has issued a special centenary number containing much matter of great interest, both historical and horticultural. The paper was first founded as a quarterly journal, by the editor-proprietors of a former paper, now defunct, entitled *Le Bon Jardinier*. The first editors were Antoine Poiteau and André de Vilmorin, a name which is still famous as that of the great Paris nursery firm of Vilmorin-Andrieux et Cie. In 1845, the paper began to be published twice monthly, and so continued until 1914, when it ceased publication, to be resumed as a monthly journal in 1915. The centenary number is full of portraits of celebrated horticulturists who have figured in the history of the past hundred years, many of them now scarcely remembered except by the names they gave to flowers or fruits of their raising, such as M. Elie-Abel Carrière, M. Joseph

---

"The Influence of Bright Sunshine upon the Tomato under Glass," by W. F. Bewley, D.Sc., *Annals of Applied Biology*, Vol. XVI, No. 2, May, 1929.

Decaisne, and M. Jules Gravereaux. Beside the historical articles, there are also monographs on various subjects by modern French specialists, and several coloured plates. The price of the number, which is additional to the ordinary monthly issue, is eighteen francs.

Proposed New Forestry Scheme for Scotland.—At a meeting of the Glasgow Corporation, held on June 13, a letter was read from Colonel Sutherland, Forestry Commissioner, containing a proposal by the Commission to feu the whole lands belonging to the Corporation at Loch Katrine, extending approximately to 24,128 acres and to afforest 7,000 acres under reservation of the water powers of the Corporation, and to pay an annual feu duty of £1,100, or such other sum as might be adjusted. By the casting vote of the Chairman, the proposal was turned down by the Water Committee, and after discussion this decision was upheld by a majority of the Town Council. The opposition to the scheme was based on the principle of dual control, which could not be permitted in the interests of the City and its water supply.

Scottish Potato Sales.—The first of the new season's crop of early Potatos was marketed the week before last from Drummore, in Wigtownshire, and digging started a few days later in Ayrshire, where the annual auction of growing crops of Epicure began on Wednesday, June 12. Favoured by suitable weather, the crops in the Girvan district have made good progress lately, and the tubers are of a nice size and quality. Although large areas had been disposed of privately, there was a large attendance of buyers and bidding was of a spirited character, especially for lots that were in a more advanced state of maturity. The highest price received so far was £70 per acre, while backward crops ranged from £29 upwards. At one farm the average price worked out at £47 11s. 0d. per acre, as compared with £40 4s. 0d. last year.

Legacies to Gardeners.—The late Miss Mary Burgate Winslow Fenwick, of Lingy Acre, Portinscale, near Keswick, who died on February 10, left £50 to her gardener, Mr. George C. Rowe.—The late Mr. Samuel Moore Segar, of the well-known florists' firm of Messrs. Wills and Segar, Ltd., who died on February 19, left £100 each, free of duty, to Mr. Corderey, Mr. A. C. Cook and Mr. Woollven, if in the employment of Messrs. Wills and Segar at the time of his decease.—The late Sir Alfred Jodrell, Bt., of Bayfield Hall, Holt, Norfolk, who died on March 15, 1929, left a house and garden at Sharrington to his gardener, Mr. James Michael Pointer, for his faithful service to him.—The late Mr. James Gallaher, of Malone Park House, Belfast, who died on February 4, 1929, left £100 each to his gardener, Mr. David Barr, and his gardener's assistant, Mr. W. Campbell.

South Australian Forest Activities.—Afforestation in South Australia receives considerable attention in Government circles, much greater, indeed, than is accorded it in any other State of the Commonwealth, and the Annual Report upon State forest administration, which has just been made available by the Commissioner of Forest Lands (Hon. John Cowan) indicates that continued progress is being made. The returns cover operations up to June 30, 1928, at which date the area of State forests was 200,005 acres. An additional 50,000 acres, however, had been purchased and was in progress of dedication, and it was further anticipated that from time to time the total area would be augmented. During the year, 6,866 acres had been enclosed and planted with softwoods. This was an advance over the previous year's performance of 2,623 acres. The maximum planting area, as laid down under agreement with the Commonwealth Development and Migration Commission, has now been attained. Necessary preliminaries for future operations were carried out, and included the raising of 6,425,391 seedlings in the nurseries, the clearing of 6,722 acres, completion of the work of fencing, and pre-pitting of the area for planting. During the twelve months under review, the Commissioner paid several visits to forest reserves, and conferred with his officers on various aspects of the operations. An important decision was to adopt the system of pre-pitting for planting, which has resulted in substantial economy without sacrificing efficiency. It was also resolved to increase the afforestation activities at Kuitpo, about thirty miles south of Adelaide. Mr. A. T. Gibson, Conservator of Forests at Lahore, India, inspected several of the State plantations, and was greatly impressed with the work of the Department.

Mr. H. W. Abbiss.—Mr. Abbiss, the Horticultural Superintendent for Cornwall, comes from an old horticultural stock, as his grandfather was a member of Sir Joseph Hooker's Australian Expedition. He received his earlier education at Tiffins School, Kingston-on-Thames, and at an early age showed such keenness for the horticultural profession that he won a Surrey County Council horticultural scholarship, tenable at the Royal Horticultural Society's Gardens, Wisley. At the end of his studentship at Wisley he was granted his diploma with distinction, and was offered a temporary extension of his scholarship for research work. The practical side, however, made a strong appeal, and he left Wisley to take up a journeyman's position in Norfolk, after a short commercial experience in Surrey. He was eventually appointed outside foreman under Mr. H. Naylor, at Lady Battersea's famous gardens, at the Pleasaunce, Overstrand. This position he held for four years prior to the outbreak of the war. He served with the colours from 1914 to 1919, being recommended on four occasions for gallantry in action; he was awarded the D.C.M. twice, and also the Military Medal; he was also wounded. After the armistice he acted as an army horticultural lecturer, returning to Overstrand in 1919, and taking charge of the glass department. It may be noted, in passing, that Mr. Abbiss was one of the first to take the examination for the National Diploma in Horticulture, which qualification he holds. In February, 1920, he became lecturer in horticulture to the Devon County Council, and this position he held until appointed by the Cornwall County Council as Horticultural Superintendent, in April, 1923. During his term in Devonshire, he did valuable work in connection with orchard renovation and the cider industry. His greatest success has, however, been achieved in Cornwall, where, realising the horticultural potentialities of the county, he has done much to improve and extend the commercial side of the industry which has its strongholds in the Tamar and Fal Valleys and on the Penzance peninsula. A recent commercial, educational exhibit, staged at the Royal Horticultural Society's hall, demonstrated what the Cornish climate produces early in the season. Mr. Abbiss originated the Commercial Spring Flower and Broccoli Show, the Soft Fruit Show, and the Dry Bulb Show of the west, the aim throughout being to improve and raise the standard of growing and marketing, to extend the area under these crops and to advertise Cornish produce. His posters of unique design in connection with this work are now well-known. Other achievements include the setting up of co-operative bulb sterilisers (one of which has already treated two hundred tons of bulbs), and the initiating of experiments in the export of Cornish Broccoli (in conjunction with the Ministry of Agriculture) to the continent under the National Mark Scheme. Working under the chairmanship of the Rev. A. T. Boscawen, V.M.H., Mr. Abbiss has received every support from the members of his committee, who have supplemented his staff to meet the increased demand for horticultural education. Although the commercial side of his work takes priority, Mr. Abbiss's duties embrace lecturing and demonstrating to all classes of growers, Women's Institute members and teachers, advisory work by visit and letter, landscape work (roadside planting, laying-out school grounds and playing fields, and the keeping of open spaces), and the supervision of school gardens. Many shows are also visited and demonstrations given in manual processes. Mr. Abbiss is also responsible for the management of several experimental stations and outdoor trial work, which obtain the best and latest information for the benefit of the industry. Through the agency of these stations many improvements have been brought about, a good example being the way in which the Broccoli industry of Cornwall has been put on a sound footing by the introduction and distribution from these stations of the Roscoff Broccoli. This has been the means of bringing an additional £10,000 into the county during the past season.

MR. H. W. ABBISS.

Mr. E. H. M. Cox to Lecture in America.—We learn that Mr. E. H. M. Cox, the Editor of the *New Flora and Sylva*, is to make a short lecture tour in America during the latter part of the present year. It is stated that his first lecture will be given at the Horticultural Hall, Boston, on October 22, under the auspices of the Massachusetts Horticultural Society.

Appointments for the Ensuing Week.—MONDAY, JULY 1: Harrogate and District Horticultural Association's meeting. TUESDAY, JULY 2: National Sweet Pea Society's Exhibition (two days); Royal Caledonian Horticultural Society's meeting; Peterborough Agricultural Society's Show (three days); Post Office Savings Bank Horticultural Society's Exhibition. WEDNESDAY, JULY 3: National Carnation and Picotee Society's Show; Brighton, Hove and Sussex Horticultural Society's Show (two days); Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Society's meeting. THURSDAY, JULY 4: Newport Horticultural Society's Rose Show; Bideford and District Horticultural Society's meeting; North-east Coast Exhibition (three days). FRIDAY, JULY 5: National Rose Society's Show (two days); British Delphinium Society's Show. SATURDAY, JULY 6: Leigh-on-Sea Horticultural Society's Show; Leeds Paxton Society's open exhibition night.

"Gardeners' Chronicle" Seventy-five Years Ago.—*How to Destroy a Noble Tree, as practised in all our public Parks.*—Take any tree (particularly a slow-growing, valuable one), measure no more than twenty feet from its bole, and then plant a Horse Chestnut or other quick-growing tree in every direction around; in a very few years the ends of all the branches will begin to decay, and in a comparatively short time you will see the last of your fine old tree, especially if, after a severe winter, you carefully abstain from cutting out any dead wood whatever. That I am only stating facts, anyone who will go into the Kensington Gardens or Hyde Park may satisfy himself. *A Constant Subscriber. Gard. Chron., July* 1, 1854.

NOTES FROM KEW.

It is remarkable the number of plants that have withstood the severity of the past winter, and the profusion of blossom that is being exhibited, although much of it appears to be short-lived compared with that of former seasons. In the rock garden many plants were cut to the ground owing, undoubtedly, to the lack of snow. The Androsaces, however, appeared to benefit by it, due to the absence of the usual London fogs and damp weather, and among those which have been exceptionally fine this spring are A. carnea, A. lanuginosa, A. primuloides and A. sarmentosa.

Among the Meconopsis, the tale is one of woe, for many of the short-lived sorts failed to come through the winter. One plant of M. grandis—it lost its brethren—sent up a stalk carrying the most beautiful blue Poppy flower. M. betonicifolia var. Baileyi has been for the past fortnight a great source of attraction, along with that charming little species, M. quintuplinervia, which hangs its lavender-blue bells singly from the apex of slender stems which arise in numbers from a central root-stock. Of the other blue-flowered species, M. aculeata and M. racemosa have made quite an attractive display, the former especially in the wild garden. M. integrifolia, the only yellow species to flower, has done so with exceeding charm.

Primula aurantiaca, now in flower, is one of the finest decorative Primulas of its kind. It is a wonderful plant, for it flowered profusely late last autumn and is now once more a carpet of golden-yellow on the ledge where it is planted. P. secundiflora, P. sikkimensis, P. chungensis, P. Veitchii, P. Bulleyana, P. pulverulenta, P. Cockburniana, P. involucrata, P. Menziesii, P. Wardii, P. chrysopa, P. microdonta var. violacea, P. × hybrida, and that charming hybrid P. Edina, are now almost at their best.

The Onosmas also appear to have benefited by the dry winter, for O. tauricum, O. stellulatum var. helveticum, O. echioides and O. albo-roseum are now flourishing as if in their native habitats.

The Saxifragas in flower are very fine and exceptionally clean, due largely to the absence of heavy winds and rain. S. Aizoon and its varieties balcana, baldensis, laeta and notata; S. cartilaginea, S. cochlearis and the hybrid of the latter two, along with S. × Gaudinii, S. × Timbalii, S. longifolia and S. Cotyledon, and a host of "mossy" Saxifragas, are making the rock garden look quite bright.

There are also quite a number of Pentstemons in flower, including P. Scouleri, and its variety alba, P. confertus, P. Menziesii, P. Eatonii and P. glaber, a form of the latter being particularly graceful, of upright habit and with blooms of a lovely shade of azure-blue, bluer far than the best Veronicas, of which there are now numbers in flower. The Aubrietias and dwarf-growing Gypsophilas are very attractive, along with Phlox subulata and its varieties, P. Stellaria and P. Douglasii, the last two very bright. Dodecatheon Meadia, D. Lemoinii, and others are very vigorous, carrying showers of star-like flowers on rigid stems, while Haberlea rhodopensis and H. virginalis, along with Ramondia pyrenaica and its variety alba, R. serbica and R. Nathaliae, are now a picture as they hang from the crevices between the rocks, sending out their dainty blue and white flowers most luxuriantly. R. Heldreichii, better known as Jankaea Heldreichii, has also flowered with us this year, but that is finished and now there is only hope of procuring seeds in the autumn. Another treasure that has flowered freely is Wildenia candida, which has produced its lovely, waxy-white flowers well above the soil and has made quite a startling little show.

In the damper places, Cypripediums are very fine, notably C. Calceolus, C. pubescens and C. spectabile, the latter being a wonderful picture in the small bog in the rock garden.

Achillea Kellereri, A. sarracinica, A. Griesbachii, A. conjuncta, A. argentea; Alyssum spinosum and its variety roseum; Eriogonum umbellatum and E. sub-alpinum, the creeping Cerastiums and Arenarias; Silenes, Antennarias, Dianthuses, etc., are all now nearing their best, and provide a splendid mass of colour.

Among the scarcer alpine plants, Omphalodes Luciliae has, perhaps, made the most remarkable recovery, and its foliage and flowers seem all the better for the winter's freezing. Tanakaea radicans is now quite attractive, although never a startling plant. Bruckenthalia spiculifolia, with its charming pink flowers and Heath-like foliage, is well worth cultivating in the rock garden, as it makes a lovely show. Silene Hookeri, its first flowers now passing over, has been very showy and of good rich colouring this year, and with the remainder of the summer in front of it, there are hopes of obtaining plenty of seeds. Geranium Farreri has been a picture; although shifted and grouped together in the early spring, it has flowered magnificently and is now in a flourishing condition. Matthiola valesiaca is a plant well worth growing in a sunny position, for it is now smothered with lilac flowers, the bushy plants being fifteen inches in height. The Lithospermums received a severe check, but are now recovering in a startling manner and, along with the Wahlenbergias, Campanulas, etc., are lending the necessary tints of blue to complete the picture. *A. Edwards, Kew.*

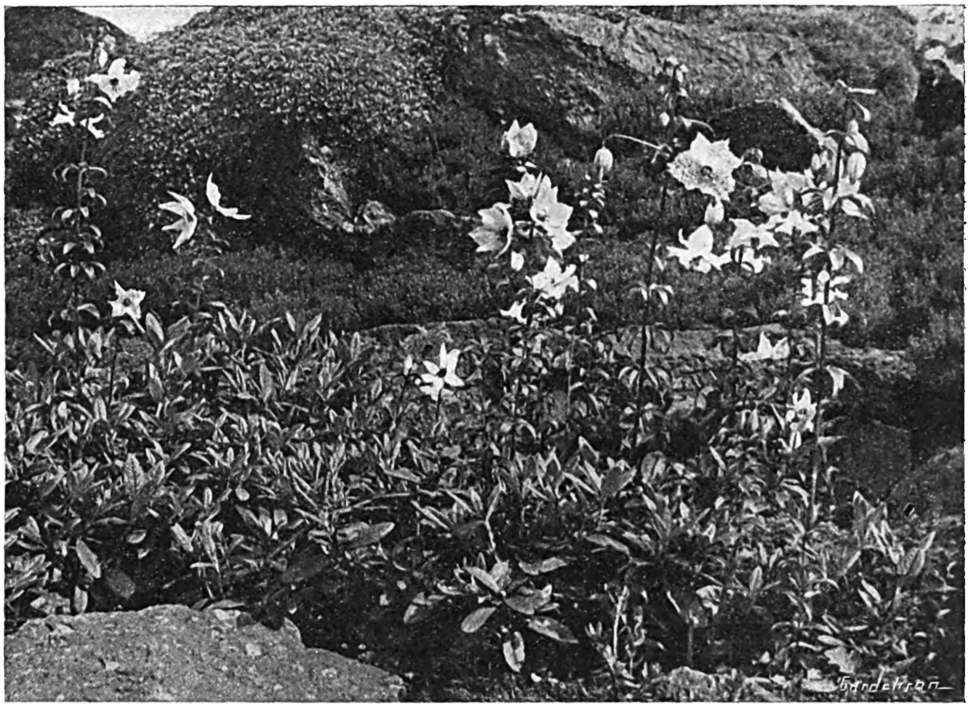

FIG. 238.—NOMOCHARIS MAIREI VAR. LEUCANTHA AND N. SALUENENSIS, GROWING AMONG RHODODENDRON SANGUINEUM AT EDINBURGH BOTANIC GARDEN.

NOTES FROM EDINBURGH.

All classes of plants out-of-doors have been benefited to a large degree recently by welcome showers and periods of bright sunshine. The garden generally has a very fresh and healthy appearance, and many plants have attained a high standard of flowering perfection, some even surpassing past records. This is true of genera like Rhododendron, Primula and Meconopsis.

The rock and wild gardens at present cater for the modern plant lover and are the chief centres of attraction. New and rare plants in flower are eagerly sought after, and much attention is given by visitors to such as may here be termed uncommon plants. The genus Nomocharis has, since the first flowers opened, had numerous daily admirers. N. Mairei var. leucantha and N. saluenensis (Fig. 238) are seen growing side by side among a clump of Rhododendron sanguineum. They seem to be quite at home here, and desire this form of cultivation, producing robust stems with some wonderfully elegant whorls of beautiful flowers. Other species of the family are equally attractive plants. N. pardanthina with rose-tinted, drooping flowers, and the variety Farreri, with dark brown spots on the inside of the petals, are very conspicuous among various Primulas and Meconopses.

Another member of the group, N. nana, only attains a height of a few inches. From its habit and dull pink coloured flowers, it may be termed a less beautiful species than those already mentioned, but is, nevertheless, an admirable plant for growing among dwarf Rhododendrons in some nook in the rock garden. This species also is of easy culture, and seeds, when sown, give a high percentage of germination.

Among the countless members of the Primula family, P. microdonta var. violacea is of outstanding merit. This fragrant form is most attractive now with violet-purple, nodding flowers thickly powdered inside with meal and giving them a waxy appearance. In the damp and coolness of the bog, P. flexilipes from western China is superb, with soft, lemon-yellow flowers, borne on delicate, slender stems, and another worthy subject from the same country, P. chrysopa, is in excellent bloom. P. Menziesiana, with rich, velvety-blue flowers, has again kept up its reputation as one of the most beautiful and attractive members of the Order. Ramondia pyrenaica, generally grown in shade on a northern aspect, has established itself on the lower half of a perpendicular dry wall facing south.

High up on a mound facing south, a few healthy plants of Aster Forrestii are in full vigour. The ray florets are of a beautiful blue colour, narrow and delicate, and with the addition of a bright yellow centre; it is a very desirable rock garden plant.

Scree plants are making rapid growth and many are in full flower. Among those of special note, Silene Hookeri from California looks happy, and shows some fine, delicate pink flowers.

The wonderful little Lychnis alpina looks at home, and is producing good spikes of bright red blooms, while a large patch of Silene pumilio clings close to the limestone and its large pink flowers nestle among the grassy foliage. Wahlenbergias also have done well. W. tenuifolia var. caricina and W. Pumilio are equally established among the stones, and many pretty, blue, Campanula-like flowers lend beauty to the surroundings.

Omphalogramma elegans growing in a damp situation is one of the best of the group. Some fine dark purple flowers opened on many specimen plants. Others of the section, *i.e.* O. vinciflorum, and O. minus, have passed out of flower.

By the pond side, drifts and masses of Primulas and Meconopsis in full bloom give a very fine colouring effect. *A. McCutcheon.*

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Selenipediums.—Members of this attractive genus of graceful Orchids have been making a fine display of flowers for many weeks. As the plants pass out of flower any that require fresh rooting material should receive attention, and repotting should be done if the plants are overgrown, or the rooting material impoverished. Robust growers, such as S. macrochilum var. giganteum, S. grande, and the varieties of S. caudatum, are best grown in pots, while pans may be used for the slender-leaved varieties, such as the dainty S. Schlimii and S. caricinum. In all cases, ample drainage should be provided, as, when established and in full growth, these Orchids require copious watering each time the soil approaches dryness. A good compost is essential, and should consist of fibrous loam, A.1. fibre and chopped Sphagnum-moss, adding crushed crocks or charcoal for porosity. Pot them moderately firmly, keeping the base of the plant slightly below the pot rim, and surfacing the compost with fresh Sphagnum-moss; this, however, should not be built up about the growths, or the danger of the latter damping off after repotting will be increased. Ample room should be left for the necessary heavy waterings required later on. If the compost is moistened through, very little water will be needed for some weeks, for at this stage the growths quickly decay if too much water is given, and the whole plant may be lost. Afterwards, when roots and growths are well advanced and growing freely, more water is necessary, and more light should be allowed to reach the plants to assist in the production of good flowering growths. Selenipediums thrive well in a moist and buoyant atmosphere at the warm end of the intermediate house, but careful attention with regard to shading and watering is necessary after root disturbance. Should the plants become infested with thrips, dipping the growths in a safe insecticide is the best remedy, afterwards tilting the plants to allow the moisture to drain away.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Protecting Fruits on Walls.—The nets for the protection of Cherries, etc., should be placed in position early enough to prevent birds from attacking the colouring fruits. The nets should be secured top and bottom, and held away from the trees by the aid of forked sticks eighteen inches or so in length; otherwise the birds may alight and peck the fruits through the nets. Earwigs, too, are a source of trouble to all wall fruits, for they eat the skin of the fruit while it is green. This pest favours a dry position, and will seek shelter in any dry place during the day, and feed at night. Small pots filled with soft moss and placed among the branches will entice the earwigs to shelter in them during the daytime. Bamboo canes, or pieces of Broad Bean haulm, cut into short lengths are also employed as traps. These traps should be examined daily and the earwigs shaken into a vessel containing some oily mixture to destroy them.

Watering.—Fruit trees on walls are rarely supplied at the roots with all the moisture and food they need to bring their crops to the fullest fruition. They are quite frequently starved at the roots by having herbaceous plants and other perennials planted close to them, the roots of these taking most of the nutriment and nearly all the moisture within their range. Even in a wet season the soil nearest the wall is generally on the dry side, and should receive an occasional soaking through the hose-pipe. This year the weather has been extremely dry (we registered less than four-and-a-quarter inches in the first five months), and there may be a danger that, in the stress of other work, this question of moisture may be overlooked. Fruit trees planted this spring should not suffer through lack of moisture and mulching, which should be renewed so often as necessary. Layered Strawberry runners, too, should be kept moist while rooting if good plants are to be secured.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Plums.—The fruits upon the earliest Plum trees will be approaching ripeness, and although syringing must not be discontinued entirely, clean and soft water only should be used with caution. A thorough syringing with soft water, to wet the fruits completely, will not injure the "bloom" up to the time of ripening, but if free from insects and well cultivated, early varieties should now ripen perfectly; where damping is the only way of producing moisture, clear water only should be used. Late varieties, such as Golden Drop, should be sufficiently advanced to receive liberal quantities of liquid manure and rich top-dressings. Keep the growths pinched closely and free from insects. Trees upon trellises may be tied in and strong shoots stopped.

Melons.—Fresh young Melon plants should still be kept at hand for use as vacancies in pits and frames occur. Seeds germinate freely after this date and the best results are obtained when the plants are put out very early, and, as the houses will be required later for winter Cucumbers, etc., the growth of these Melons should be hastened so much as possible. Melon culture after May is easy enough, the main requirements being a good bottom-heat; sound loam and old lime-rubble as compost, and careful attention to airing and watering. Plants will then go forward to the finish without a check, the foliage will not ripen before the fruits, and the latter will be of good quality. Frame culture of Melons in the autumn requires very careful attention. The compost should always be on the poor side, as it is much easier to feed the plants than to repress strong growth. The bottom heat should be kept steady, especially when the fruits are setting, as a mishap at this period will not only cause loss of time, but may throw the plants into gross growth. June has been all that could be desired, and the Melon plants have made rapid progress, but the weather may change, and it is important that the manure linings are kept in good order, and mats are placed on the frames at night.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Alpine Plants.—The early-flowering alpines have now made sufficient growth to provide a supply of cuttings. Where an increase in quantity is required, it is desirable to prepare a frame for them, but if only a few plants of each sort are wanted, the cuttings may be inserted in pots filled with a sandy compost, and stood in a cold frame and shaded from bright sunshine until rooted, or under bell-glasses in prepared beds in the open, preferably in a position with a northern aspect. The latter is the more satisfactory method, requiring very little attention until the rooted cuttings are ready to pot on. The compost for such should be several inches deep, of an open, porous nature, and composed principally of sand and old loam, with little or no leaf-soil. A bed of pure sand may be used with advantage, provided immediate attention can be given to potting on so soon as the cuttings are rooted. If the frames are placed in full sun they will require shading, using tiffany or some such material rather than lime wash, as the latter cannot be removed temporarily during dull weather. Keep the frames close until there are signs of growth then gradually admit air, increasing it as the cuttings become rooted. Cuttings of Phloxes, Alyssums, Aubrietias and other early alpines, if inserted now, will make useful plants by early autumn.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Plumbago capensis.—This is a very useful plant for grouping in the conservatory during late summer, blossoming as it does when flowers are none too plentiful. Plants that were propagated last season should now receive their final shift into eight- or nine-inch pots. After this operation the flowers should be pinched off during the next six weeks or so with a view to securing a good display later on. This subject is not particular with regard to soil, but it thrives best in a light, open compost. The plants should be grown in a cool greenhouse, and should be syringed at least once a day to keep red spider in check, which pest is very partial to this plant. When the specimens are approaching the flowering stage the roots may receive liberal doses of liquid manure and soot water, and an occasional dressing of a good fertiliser.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Tomatos.—These are now growing freely and should be tied up and have all side-shoots pinched out. When the plants have set four or five trusses of fruits, the tops may be pinched out to check vegetative growth, and so assist the fruits to swell and ripen. Liquid manure should be applied once a week until the first fruits commence to ripen, when the applications should cease.

Mulching.—Should the weather continue to be dry, and if plenty of mulching material is available, Runner Beans, Peas, Onions, etc., may, with advantage, receive a liberal mulching between the rows. These crops should also receive heavy soakings of clear water at regular intervals.

Broccoli—These should be planted at once if good, strong plants are to be obtained by the autumn. Should the ground be dry and rain is likely to occur, it is advisable to defer the planting until the ground has been moistened by rain.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—In certain districts Onions are often attacked by mildew, which soon plays havoc with the crop if measures are not taken at once to check it. Where it has appeared in former years, preventive spraying with lime-sulphur should be carried out, and the same course adopted when an outbreak occurs. Leeks sown in frames should now be ready for planting out, and should be attended to at once. Heavily manured and well cultivated ground is necessary, and as Leeks constitute one of the main winter crops, some little trouble should be taken with them. Where there is difficulty in wintering Broccoli owing to frost damage, they should be planted in a plot which has not been cultivated or broken up in any way, in holes made with a crowbar, if necessary, and filled with old potting soil to give them a start. The resultant growth will be so firm that even the severest weather will not affect the plants.

Gooseberries.—These should be watched carefully for caterpillar and mildew. For the former, dust with Hellebore powder, or with Katakilla at the first appearance of the pest. For mildew, spray with lime-sulphur, one part to one hundred parts of water.

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

Anemone demissa, choice member of a charming genus, was collected in the Himalayas and named by Sir Joseph Hooker some eighty years ago, yet it seems to have fallen out of cultivation in private gardens, and I can find no reference to it either in plant catalogues or works on horticulture. Some kind friend must have sent me two plants of it a couple of years ago, and it has proved a valuable acquisition. From a flat rosette of deeply lobed leaves it sends up, in mid-May, sturdy stems bearing clusters of five or six white flowers, each with a centre of golden anthers. The blossoms are fully expanded by the time these stems are six inches high; but before they fade they are held aloft at a height of eighteen inches or two feet, and the leaves also rise from lying flat on the ground, a position which, I suppose, earned this Anemone its specific name. The sepals are of a strong opaque white, compared with which those of the mysteriously named A. narcissiflora seem almost dingy; but those of A. rupicola stand comparison very well with this newcomer to my border.

Humbler in stature than A. demissa, but with flowers double the size, A. rupicola is an equally attractive Windflower. Reginald Farrer was as relentless in condemning what did not take his fancy as he was lavish in praise of what pleased him. It is difficult to understand his classing A. rupicola among species which he dismisses as "obscure, indistinct, and of no great value," for its cheerful white salvers surely entitle it to kindlier notice. Referring again to A. demissa—it demands a moist root-run, and is apt to shrivel in a dry border or rockwork shelf.

Most Rhododendron species have flowered abundantly in our district this year, with the notable exception of R. arboreum and R. barbatum, reacting from their profusion in 1928. The prolonged cold of the past winter and early spring was beneficial in retarding growth on those species which, starting into growth early, often suffer sadly from late frosts. These are now full of promise for next year. Grateful as we must feel for the brilliant warmth we have enjoyed in June, it shortens sadly the display of late-flowering species and hybrids; but the gorgeous colours of R. Roylei and R. villosum are only revealed when viewed against the sun. It is well, therefore, to plant them clear of other growths. The hue of the flowers of R. villosum is often decried as crude magenta, and it is true that it varies considerably in different specimens; but the effect of a richly coloured bush with the sun shining through its crowded blossoms entitles this species to high rank in the 'Triflorum' series.

Among June-flowering Asters there are many inferior and none superior to A. Forrestii, which I had lately the privilege of viewing in the Edinburgh Botanic Garden in company with its discoverer. Its fine, flat flowers are borne erect on twelve-inch stems, the soft lavender of the ray florets contrasting admirably with the golden disks. *Herbert Maxwell, Monreith.*

ALPINE GARDEN.

GENTIANA KOCHIANA VAR. DINARICA.

This plant is now known as a variety of G. Kochiana, Perr and Sorg, along with G. exisa, etc., and if the whole series be grown, it will quite readily be seen there is but very little to distinguish the various forms found throughout the European highlands. The variety known as dinarica (Fig. 239) is stated by the late Reginald Farrer (*The English Rock Garden*), to be somewhat scarce, being confined to a small area in Bosnia and one or two places on the eastern flanks of the Alps. The leaves are, as a rule, rather smaller than those of G. Kochiana or G. exisa, and a little more diamond-shaped; but then, should a batch be raised from seeds, or grown in a sheltered position, this character may, probably, be found to be variable. The outstanding difference, perhaps, between G. Kochiana and its variety dinarica is the lack of spots in the corolla throat of the latter, which is of the brightest blue, with greenish bands on the outside, rather longer and more cylindrical than those of its allies, being upwards of three-quarters-of-an-inch in diameter and borne on stems of one to two inches in length, varying under differing conditions.

These Gentians will be found to do best in gritty soil, where they will not obtain too good a living and so tend to reproduce themselves by seeds rather than vegetatively, as so often happens in areas surrounding our larger towns. *A. Edwards, Kew.*

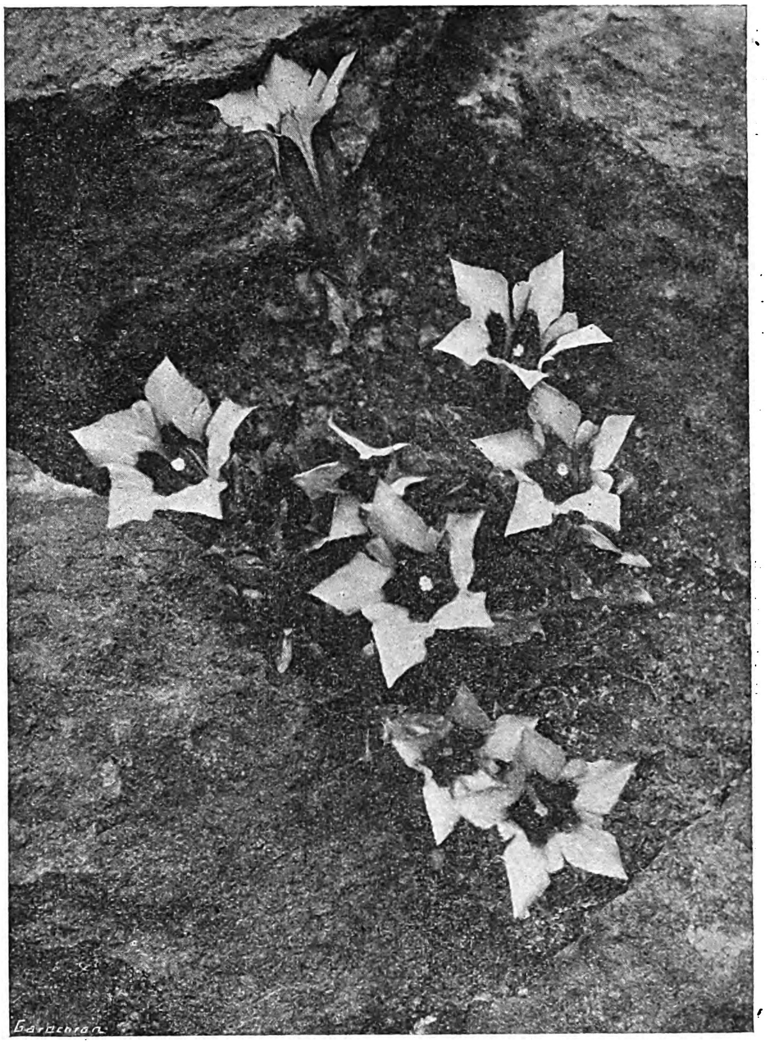

FIG. 239.—GENTIANA KOCHIANA VAR. DINARICA.

DIANTHUS SQUARROSUS.

This dwarf Pink from Russia and Siberia is an old favourite among alpine gardeners, for it is one of the easiest to grow, is of compact and tidy habit, and every year produces, during June, its crop of beautiful flowers above a compact mound of grey-green, slender, stiff or recurving, pointed leaves.

The flowers are of a lovely, clear, pure white, sometimes tinged with pink, and the petals are very finely cut, so that the mass of flowers produces a flimsy and lace-like effect, the blooms being borne either singly, or in clusters of two or three, on slender stems eight or nine inches high.

D. s. var. nanus is a desirable dwarf and compact variety, carrying its flowers on stems barely six inches in length, and there are several other minor forms, which have been named at various times.

D. squarrosus is a good grower and very accommodating, and may be planted either in rock crevices or in beds or rock pockets, its only requirements being sunshine and a well-drained root-run, in stony, light, loamy soil. *M. W.*

IRIS GARDEN.

IRIS VERSICOLOR.

The American Iris versicolor makes a gay display of colour during the months of May and June. It occurs abundantly in this locality, inhabiting wet meadows, marshes and the banks of streams; and is sufficiently attractive to make it a worthwhile subject for similar situations in the garden. Attaining a height of from one-and-a-half foot to three feet, the flowering stems are usually branched above, and forked near at the base. The erect, sword-shaped leaves are shorter than the flower stems and are slightly glaucous.

The flowers are violet-blue in colour, variegated towards the centre with green, yellow and white. They are short-pedicelled, with the spathulate outer segments two or three inches long, and the flat petals about half that length. The perianth segments are glabrous and crestless, and the perianth tube is much shorter than the obscurely three-lobed ovary, which has three cells, each containing two rows of seeds.

Iris versicolor enjoys a wide distribution on the Continent of North America, being found from Newfoundland to Manitoba, and southward to Florida and Arkansas. It was introduced to England so long ago as 1730, and is figured in the *Bot. Mag.*, t. 21,703. *T. H. Everett, New York.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER ; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXIV.—AT CAMP V.

SO at last we were within striking distance of the Alps! During the next week, before the monsoon flooded us, we explored the ridge. It was no easy stroll to the alpine region, for the ridge twisted and bent, dropped down, climbed up again, and was frequently shattered; but there was a hunters' path all the way. Rhododendron Roylei was in fine bloom all along the rockier crest of the ridge, its colour varying from tawny orange to a flushed brick-red; and with it was the purplish-flowered shrub, like R. tephropeplum (Fig. 242). Among the Bamboos, irregular mounds of dark green, from which peeped flakes of rusty red wool and clusters of succulent crimson bells, suggested R. haematodes. The pink 'Barbatum' was still in full bloom, and scattered among it was the big-leafed 'Barbatum' whose stems are clothed with the persistent bud scales of years. I first noticed this species in the Tsangpo Gorge in 1924. In 1926 I found it in the Seinghku valley, and obtained seeds. Now, at last, I saw it in flower, and a splendid plant it is. The flowers are a vivid carmine-crimson without spot or blemish, tightly crammed into big, round heads; and the breaking of the leaf buds is an event, for the long, thin bud scales spurt out in a pink fountain which never ceases to play until the leaves expand.

Higher up the ridge, where the stout Fir trees grew further apart, much of the undergrowth was composed of a bushy 'Thomsoni' Rhododendron, just opening its glossy, scarlet bells in peals of five; at the base of the corolla are five circular jet-black glands, recalling another Tibetan species named Coals-of-Fire. Then, as the uppermost Abies forest was approached, one brushed through thickets of 'Sanguineum,' glowing duskily in the hollows, and tramped over tuffets of purple 'Saluenense' on the windy tops; and so to the Alps. Other species on the long ridge were the peevish-yellow R. trichocladum, and a 'Brachyanthum' with small flowers of an uncertain plum-juice colour. Most remarkable of all however, was the scarlet 'Neriiflorum,' which in the middle forest remained in flower until June was nearly spent, having then been in bloom for two months.

But Rhododendrons, although the most numerous, were not the only trees and bushes in the forest. Even on the ridge were species of Enkianthus, Rowan, Viburnum Wardii, Clethra, an Ilex rather like I. dipyrena, and Acer. In the gullies were many fine trees of Magnolia globosa, which flowered in the middle of June. In the Seinghku valley, where I first met with it, Magnolia globosa was no more than a bush or large shrub, its leaves glistening with long, champagne-coloured, silky hairs, and it flowered shyly. Here, as in Sikkim, it was a stout tree, but leaves and shoots were much less hairy than the Seinghku form, and it flowered freely. The flowers are globular, not opening widely, snow-white with purple anthers, and half pendent. Although M. globosa lacks the splendid foliage of M. rostrata, the flowers are quite as large as those of that species, and much more easily seen among the leaves.

There were a great many small shrubs scattered in the forest, amongst others Ilex Pernyi, Berberis Wallichiana, species of Deutzia, Ribes, Cotoneaster, Euonymus, Lonicera and Rosa, this last having small, pink flowers and smooth, scarlet, flask-shaped fruits.

Where the rock foundations of the ridge burst through the forest lining, the barren-looking cliffs harboured Primulas and other rock plants. Wedged into crevices, so far out of reach as it could shrink, was a tiny 'Auriculata' Primula, with purple, starry flowers, single or in pairs, clasped by toothed, spoon-shaped, mealy-white leaves; and at the cliff-foot, wherever there was a little free earth grew a comely 'Denticulata' with mop heads of mauve flowers. I collected seeds of this in the Di Chu valley in 1926 (probably K.W. 7,133) and now that I have seen it in flower I can commend it. Thirdly, there was a Muscarioid Primula with a miniature mop of violet flowers dimmed with white meal; a gentle, downy creature, well-meaning but without distinction. All these three were children of the Alps which had strayed along the ridge like lost sheep and seized on the freehold of these unoccupied waste lands in the forest estate.

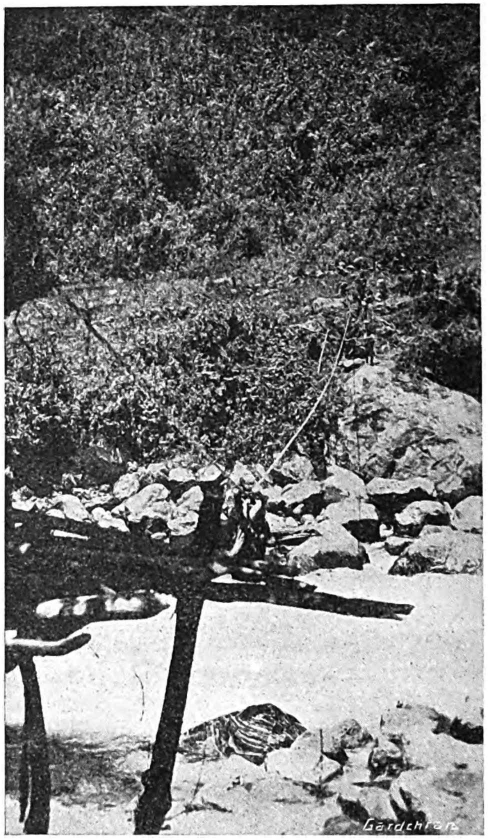

FIG. 240.—A MISHMI ROPE BRIDGE OVER THE DELEI RIVER.

But I also found three real forest Primulas which did not run for the alpine stakes. The first was discovered while following down one of the gullies in the search for water—a notable addition to the Geranium-leafed Primulas. The flowers which are bright purplish-pink with orange or crimson eye (a bicolor peculiarity it shares with the dainty P. eucyclia) and frilled petals, are massed in compact heads containing a dozen or more flowers and a single plant may bear four or five scapes which stand up freely above the jungle of palmate leaves. These leaves redden in the autumn. This plant grew in teeming masses on the steep flanks of the heavily wooded gullies, near their heads, under the shade of Rhododendrons, Tsuga and Magnolia globosa. Lower down in the same gullies, where running water had washed the coat of soil off the striped gneiss, there appeared a fine, butter-yellow Primula which anyone might have mistaken for a short thick-set 'Sikkimensis.' When it first opened it possessed but one tier of drooping bells, with, perhaps, a hint of a second; an arrangement met with in many of the 'Sikkimensis' group (and others, *e.g.*, P. seclusa) attaining a record in some forms of P. microdonta alpicola, which are four stories high. Nor was there anything about the foliage to exclude 'Sikkimensis' affinity. But when the masker grew to a ripe old age, it was seen that it did but jest; the globular capsules, now in three tiers, lined with small, black seeds, marked it a 'Candelabra,' although our new sunny-yellow Primula was still a Rose by some other name. Its affinities are clearly with P. prenantha—which by the way, also grew on the grassy ridge beneath Bamboos and Rhododendrons—and still more with the Tibetan P. Morseheadiana. As for the former, it is a rather poor thing, of diminutive stature and narrow tubes—I collected seeds of it in 1926; as for the latter, collected in that paradise of Primulas, the Doshong La, in 1924, I have never heard that it throve in England.

The sunny 'Candelabra' was not common, and was invariably associated with the 'Geranioides' described above; the one began where the other left off, and if you met with hundreds of 'Geranioides' Primulas at the head of a gulley, you could bet with certainty on meeting a few dozen 'Candelabras' below.

The third forest Primula was also Geranium-leafed, twin brother or sister to P. septemloba, a poor thing with puny, purple flowers in weeping tresses. Well might they hang their diminished heads, having degraded the noble name of Primula. Yet, thanks to its woolly-whitened leaves, which are large and well-shaped, the plant looks decently tidy. I wonder if it really *is* P. septemloba—how odd that would be! Only after careful comparison of the specimens can a final decision be reached.

It is worth noting that the new 'Geranioides' described above and P. eucyclia, both of which grow in places damp and dark—the latter often growing on cliffs over which water is splashing and trickling—are practically glabrous. On the other hand, P. septemloba from the drier woods of north-west Yunnan, and its twin referred to above, as well as P. latisecta from the Tibetan forests, are all quite hairy; a hint for cultivators.

Just as the 'Candelabra' (which, by the way, was wholly without meal) and the glabrous 'Geranioides' were always found in company, so the hairy 'Geranioides' was always found in company with a red-flowered 'Sikkimensis,' of which more later.

One other Primula must be mentioned here—a dwarf 'Sikkimensis' with small, rounded, petiolate leaves and large creamy flowers. I know nothing more about its habits than that I found half-a-dozen plants on a grass slope at the back of a rock which stuck up from the forested ridge, like a fang. I never saw the plant again, although I searched many likely and unlikely places.

One of the commonest plants all along the upper part of the ridge and well into the alpine region, was the violet-flowered Omphalogramma Souliei. It grew here in countless thousands, just as it did in the Seinghku valley. In the dawn of spring a coral-red spear bayonets its way through the clogged earth, whence the snow has barely lifted its weight; then the big, violet flower opens, almost resting its chin on the ground. Lastly the leaves appear, and continue to grow all the summer, and the scape lengthens until the fruits may be twelve or fifteen inches high. But the plant is at its best when the tightly-packed clumps are first opening, with the violet flowers impaled on red spears.

The cliffs afford shelter to a few plants, including a spotted Fritillaria, a striped, white Lloydia, the yellow-flowered Diapensia Wardii in large, hard mats; Pinguicula alpina, a dark violet form of Isopyrum grandiflorum, Cassiope selaginioides, and a bristly Onosma whose flowers hovered between blue and red, and generally succeeded in being neither.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, and 15, 1929.

A purple Roscoea, probably R. humeana, flowered towards the end of June. In the forest there grew sparingly a species of Podophyllum remarkable for its large, peltate, polygon-shaped leaves. The flowers are nothing, but are followed in September by big, scarlet balloons, dangling in bunches beneath the green pentagonal roof. P. Emodi, however, is not found here; it haunts the drier forests over the ranges to the north and east. Another forest plant worth mentioning was a good species of Nummularia, which was common in the gullies where the woodland Primulas grew.

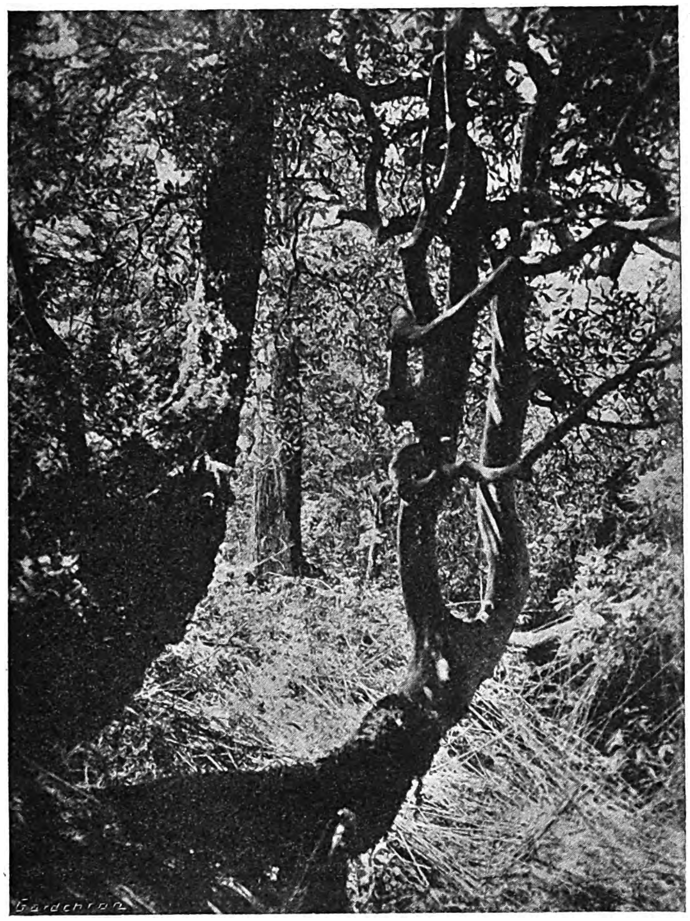

FIG. 241.—GNARLED BOUGHS OF TREE RHODODENDRONS.

Before we had been ten days in this camp, that is to say, early in June, we suffered another minor misfortune; our interpreter, Hubble, tired of drawing water, bolted, and we heard later from the villagers that he had returned to Denning. This defection had various consequences. We were reduced to one servant, our cook Luso, for the remaining five weeks, and there was no one to accompany me when I went out. But the loss of Hubble was most seriously felt in another direction. During the rains, drying paper in that saturated atmosphere with the rain always beating down and the mist sweeping through the forest, was a difficult business. We had built a small *basha* for the purpose, with a fire beneath; but the fire needed constant attention, either to keep it alight, or to see that it did not get out of hand. This extra work now fell on Luso, or on me; and although the water problem had by this time solved itself, Hubble's other job of cutting firewood, also fell on Luso. One day the long-expected event happened—we got a huge conflagration going in the paper *basha*, neglected it for a time, and set the whole thing alight; quite a lot of drying paper was consumed before the brigade arrived!

When Luso got fever, much of his work devolved on me; so that altogether I could by no means devote myself entirely to those pursuits which had brought me here. *F. Kingdon Ward.*

RULES AND RECOMMENDATIONS FOR THE NOMENCLATURE OF GARDEN PLANTS.

The Royal Horticultural Society, in view of the discussion which is to take place at the International Horticultural Conference in London next year, recently set up a Committee to reconsider the rules and recommendations which have been proposed from time to time for the naming of garden plants. This Committee has now reported, and we give below the text of their Report, which the Council has accepted.

I.—Introduction.

1. European botanists and most botanists outside Europe are guided in the naming of plants by the principles, rules and recommendations laid down at the International Botanical Congress of Vienna in 1905, in *Regles internationales de nomenclature botanique*, and extended at Brussels in 1910.

2. These rules and recommendations are framed:—
   (a) To avoid or discourage the employment of forms or names liable to produce errors or uncertainties, or to bring about confusion.
   (b) To avoid the creation of duplicate names.
   (c) To avoid the alteration of a name or combination of names except for weighty reasons founded upon a thorough knowledge of the facts, or the need of abandoning nomenclature contrary to the rules.
   (d) To deal with subsidiary but important points, such as grammatical accuracy, regularity and euphony.

3. The "Rules" point out that a name is given, not to express the characters or the history of the thing named, but as a means of understanding one another when speaking or writing of it.

4. The principles upon which the choice of a name is based are briefly, that:—
   (a) Each natural group of plants can bear but one valid name.
   Note. By natural group is meant the groups into which botanists divide the vegetable kingdom, viz., for example:—
      Divisions (Fungi, Spermatophyta).
      Classes (Dicotyledons).
      Families (Ranunculaceae, Papaveraceae).
      Genera (Ranunculus, Papaver).
      Species (bulbosus, repens, somniferum).
      Varieties.
   (b) The name, to be valid, must conform to the rules and is the oldest conforming name used after a date fixed for each division of the vegetable kingdom.
   (c) For all groups of vascular plants, nomenclature begins at the year 1753.

5. The rules and recommendations governing the form of names of species are, briefly:—
   (a) All species are designated by the name of their genus followed by a name termed specific. Thus all names of species consist of two words.
   (b) Generic names begin with a capital letter. Specific names begin with a small letter, except those taken from names of persons (*e.g.*, Anemone Halleri, Ceratostigma Willmottianum), or from generic names (*e.g.*, Brassica Napus).
   (c) Specific names taken from the name of a man are made by adding "i" when the name ends with a vowel (*e.g.*, Pittosporum Bureaui, or P. Mayi) except when it ends with "a" (*e.g.*, Balansa becomes Balansae); by adding "i" when it ends with "er" (*e.g.*, Kerneri); by adding "ii" when it ends with any other consonant (*e.g.*, Smithii). When taken from the name of a woman, the name is written in the feminine (*e.g.*, Cypripedium Hookerae, Berberis Wilsoniae).

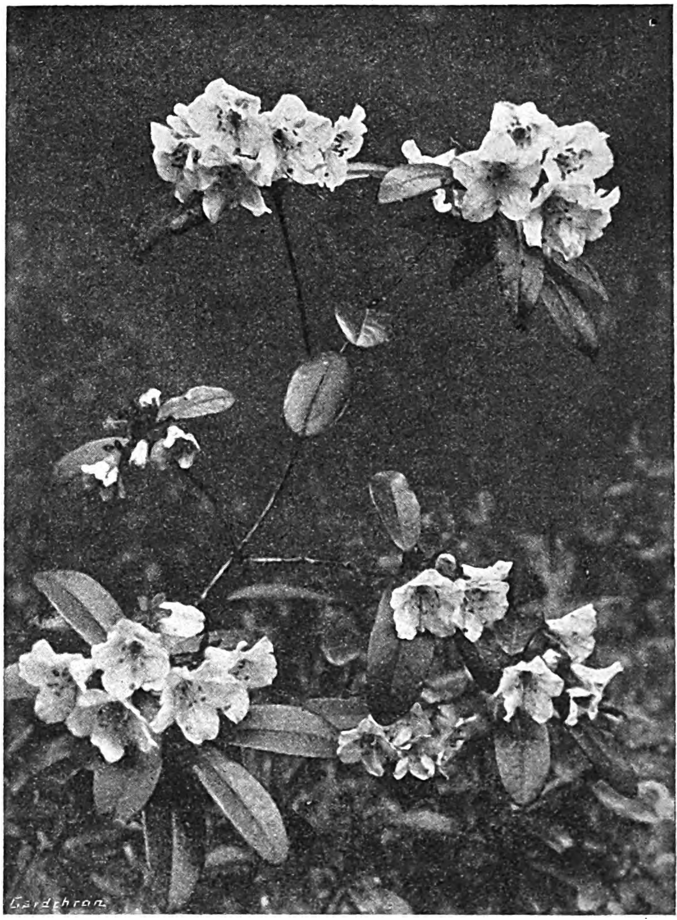

FIG. 242.—A HANDSOME BUSH OF RHODODENDRON SP., ALLIED TO R. TEPHROPEPLUM.

(d) The specific name is of the same gender as the generic, but most classical names of trees and shrubs are feminine, although they may end in "us," *e.g.*, Ranunculus bulbos*us*, Anemone nemoros*a*, Geranium pratens*e*, Dierama pendul*um*, but Quercus sessiliflor*a*). The most convenient guide to the correct spelling of plants names is probably *Index Kewensis*.

(e) Two species in the same genus cannot bear the same specific name.

II.—Difficulties arising out of a Strict Application of these Rules for Horticultural Purposes.

6. Botanical research brings about continual changes in nomenclature, and old names may be discovered and revived, or new combinations may be introduced at any time and may gradually come into general botanical use. To adopt such names as and when they appear in botanical literature would cause constant changes in catalogues and in labels in gardens, and to avoid this it is suggested that:—

(a) A list of names valid at the time it is made should be drawn up and should be good for, say, six years. It is imperative that this list should follow strictly the Rules of Botanical Nomenclature so far as species and botanical varieties are concerned, and that the names of plants generally accepted as conformable to the rules at the time of the making of the list should alone be used. All personal preferences and individual usage must be sunk if not in conformity with these rules. This list should be used universally in catalogues, horticultural literature and gardens for the fixed period.

(b) An International Committee should be appointed to revise this list in the light of botanical research at intervals of six years.

(c) Such alterations as are admitted at these revisions should be shown thereafter in catalogues for the next period with the superseded name as a synonym.

7. When the delimitations of a natural group are varied by different botanists, and there is a clear absence of concerted opinion in favour of one delimitation, the International Committee would choose the one best suited to the interests of international horticulture. For instance:—

(a) We are of opinion that the division of large genera in which fairly well marked groups are found, such as *Pyrus*, into Pyrus, Sorbus, Cydonia, etc.; *Prunus*, into Prunus, Amygdalus, Padus, Cerasus, etc.; *Berberis*, into Berberis and Mahonia, better meets horticultural needs than the retention of all the species in each under one generic name.

(b) Similarly, it may be found that what to some botanists are but subspecies of a large group species (as, for instance, *Saxifraga Friderici-Augusti*, *S. media*, *S. thessalica*, *S. montenegrina*, which are treated by Engler as subspecies or varieties of S. porophylla) are better treated for horticultural purposes as separate species.

These, being matters of personal opinion, should be decided by horticulturists for themselves, but it is essential that international agreement should be arrived at upon each name.

8. In addition to species and varieties occurring wild, horticulturists have to deal with varieties raised in gardens, and although these varieties are not in essence dissimilar from the wild varieties, yet their nomenclature is not fully provided for in the Rules. Special rules need, therefore, to be made for them. The principles laid down apply all through.

III.—Rules and Recommendations for Naming Horticultural Varieties and Hybrids.

9. Proposed rules and recommendations:—

(a) The name of a horticultural variety should be placed after that of the species to which it belongs, and its status should, or may be indicated by the contraction "var."

(b) It should be of Latin form, only when it expresses some character of the plant, *e.g.*, *nanus, fastigiatus, albus*, or its place of origin as, *e.g.*, *kewensis*. The use of Latin proper names for horticultural varieties is proscribed, *e.g.*, Iris pallida Smithii would be an inadmissible name for a garden variety.

(c) The name will thus usually be a "fancy" name, *e.g.*, *Galega officinalis* var. "George Hartland," not *Hartlandii*; *Dianthus deltoides* var. "Brilliant," not *brilliantissimus*; Pea "Masterpiece."

(d) "Fancy" varietal names should be in Roman characters, those of Latin origin, like those of species, in Italics.

(e) Varietal names must not be translated when transferred from other languages, but must be preserved in the language in which they were originally described. Where desirable a translation may be placed in brackets after the varietal name.

(f) As far as possible, names of horticultural varieties should consist of a single word; the employment of not more than three words is permitted as a maximum.

(i) Varietal names already in use for one variety of one kind of plant should not be used again for another variety of that kind, even although they may be attached to a different species. That is, *e.g.*, the use of the name Narcissus Pseudo-narcissus "Victoria" should preclude the use of "Victoria" as a varietal name for any other species of Narcissus, such as Narcissus poeticus "Victoria." Similarly, there should be but one Iris "Bridesmaid," one Plum "Superb," and so on.

(ii) Names likely to be confused with one another should be avoided, *e.g.*, the use of the name Iris "Alexander" should preclude the use of "Alexandra," "Alexandria" and "Alexandrina."

(iii) Where personal names are used to designate varieties the prefixes, as Mr., Mrs., Miss, and their equivalents, should be avoided.

(iv) Excessively long names and words difficult to pronounce should be avoided.

(v) The articles "A" and "The," and their equivalents, should be avoided in all languages, where they do not form an integral part of the substantive. *e.g.*, "Colonel," not "The Colonel" "Giant," not "The Giant"; "Bride," not "The Bride."

(vi) Existing names in common use should not be altered to conform to these rules, but attention should be paid to them in all new names proposed.

(g) The specific names of horticultural hybrids (*i.e.*, crosses between species) are to be expressed in one word in Latin or in any language written in Roman characters:—

e.g. Cypripedium × Goliath,
,, × Aylingii,
,, × nitens,
,, × burfordense,

are all of correct form.

All plants arising from the crossing of the same two species, either way, bear the same specific name.

The different forms of these hybrids are designated in the same way as horticultural varieties of species, but a specific name in the vernacular may not be followed by a Latin descriptive varietal name (*e.g.*, such a name as Cattleya × "Goliath" immaculata is inadmissible.)

(h) The generic name of a bigeneric hybrid (*i.e.*, a hybrid between species of two different genera) is designated by a formula showing the parental names in alphabetical order, or by the name of one of the parent genera, or by a name compounded of the names of both parent genera:—

e.g. Laelio-Cattleya,
Urceocharis,
Chionoscilla.

(i) Multigeneric hybrids (between species of three or more genera) are also designated by a formula and/or a conventional name preferably that of a distinguished person, to which is added the termination *ara*. Examples:—*Potinara* and *Vuylstekeara*.

Note.—The names for trigeneric hybrids already in use, *e.g.*, Brasso-laelio-cattleya, should be retained. All hybrids in which the same genera are combined receive the same generic name, no matter how they were combined; *e.g.*, the same generic name would apply to all combinations of the genera Brassavola, Cattleya, Laelia and Epidendrum.

(j) In order to be valid, a name must be published.

(k) The publication of the name of a horticultural variety or hybrid is effected by a recognisable description, with or without a figure, in English, French, German, Italian or Latin.

(i) The description must appear in a recognised horticultural or botanical periodical, or monograph, or other scientific publication, or in a dated horticultural catalogue.

(ii) The mention of a variety without description in a catalogue or in the report of an exhibition is not valid publication, even if a figure is given. It is desirable that descriptions of new varieties in horticultural catalogues should also be published in periodical horticultural papers.

10. It is suggested that the starting point for nomenclature of horticultural groups should be (a) some recognised horticultural monograph; or (b) an *ad hoc* list of varieties drawn up by a recognised body of specialists in the particular group; or (c) where such bodies do not exist, by some recognised Society which shall be specially charged with the work. Such lists should be kept up to date by (b) and (c) and additions periodically published through some recognised medium. It is also suggested that in each country the chief horticultural organisation should charge itself with the duty of transmitting all publications in which new varieties are described, and the accounts of all trials in its particular area to the body (b) or (c) concerned in maintaining the lists.

HARDY FLOWER BORDER.

LUPINUS POLYPHYLLUS VAR. MOERHEIMII.

What a magnificent flowering subject this beautiful herbaceous Lupin is! And yet it does not seem to enjoy the popularity it deserves, although there seems to be no reason why it should not be planted extensively.

In the first place it is an ideal Lupin for planting in the herbaceous border of limited size, for I think I am right in stating that it is one of the most, if not the most, compact-growing of the varieties of L. polyphyllus. Also, being compact in habit, it does not become so untidy as many, whose foliage takes on a rather bedraggled appearance as the season advances, and, under the most congenial conditions, I have not seen it raise its compact flower spikes to more than a little over two-and-a-half feet in height; two feet is usually about its limit. Added to these qualifications is another—a very important one—and that is, the flowers are of a rich rose shade, quite distinct and very pleasing, so that bearing all these points in mind, it must readily be admitted that L. p. var. Moerheimii is a first-class herbaceous perennial.

In the large herbaceous border it should be planted in groups near the front; a dozen plants together would not be too many, for it lasts in flower from early June throughout the greater part of the summer, especially if the flower spikes are removed so soon as finished. It is also very effective if used as a bedding plant, a whole bed planted solely with it producing a very telling effect in the summer flower garden, the erect flower spikes rising in their masses above the compact clusters of rather light green foliage.

L. polyphyllus var. Moerheimii has been long enough in cultivation to have become better-known, for it was introduced into cultivation by Messrs. B. Ruys, of Dedemsvaart, in 1906-7. *W.*

SALVIA VERBASCIFOLIA.

UNDER the above name, which may not be the right one, I have been growing for many years an interesting Labiate. A herbaceous perennial, this plant has thick, fleshy roots, and sends up in spring grey-green, downy leaves, which are narrowly oval in shape. Their upper surfaces are curiously wrinkled and the underparts, which are deeply netted with veins, are covered with a thick, creamy felt. Since these leaves are often well over one foot long and about half as wide, the plant has its attractions as a foliage subject. But before the leafage is fully developed several flower stems of one foot to two feet in height ascend from the centre of the tuft. Upon these are borne pendulous, tubular flowers of the typical Salvia pattern. The corollas are about the size of an average Foxglove bell. They are pure white, but have a faint etching of violet at the throat, which is hairy.

S. verbascifolia is hardy and quite permanent in a really well-drained, light soil. Excessive winter moisture is liable to cause root-rot. Propagation may be carried out by division of old clumps, but seeds, which are produced freely, provide the better way, for the plant resents disturbance. The seeds, moreover, germinate very easily, and I have had open-ground seedlings bearing flower spikes when only a year old. *A. T. J.*

FRUIT GARDEN.

TAR DISTILLATE WASHES.

DURING the past five or six weeks I have visited several gardens and orchards where the fruit trees had been sprayed with one or other of the various forms of tar distillate for the destruction of winter moth eggs, but which gave varying results in the same garden or orchard. One case was particularly disturbing. A five per cent. spray of a well-known brand gave a perfect kill in one plot, while it failed absolutely in the plot next to it. The trees in this plot, planted with Cox's Orange Pippin, had scarcely a whole leaf left on them. I was assured that one man did all the mixing, and that the same men did the spraying; yet in the one plot the trees were reasonably clean, while in the other the trees looked as though a fire had passed through them, so brown and leafless were they in appearance.

Unfortunately, no record was kept of the dates of the various sprayings, for, if so, the weather which immediately followed, such as rain or severe frost, could be ascertained, and possibly something valuable would have been discovered. The spraying, I was told, was carried out on two dates, and the weather, although windy, was mainly dry.

It is generally recognised that if rain comes during spraying operations, those trees on which the spray has not become dry had better be sprayed again when the conditions are right; but I do not know of any statistics which give the exact number of hours between spraying and rainfall which nullifies the effect of spraying. If rain has a nullifying effect on tar oil washes, what effect has frost? Is it not possible that the five per cent. wash put on the Cox's Orange Pippin trees in that orchard was followed by a hard frost? It seems the only conclusion at which one can arrive in the circumstances.

In each case the fruits were attacked and rendered useless, as well as the foliage, so that two years must elapse before the trees have recovered sufficiently to bear a crop of fruits. Obviously the grower should have been on the alert and sprayed with arsenate of lead during the "pink blossom" stage, or immediately the bulk of the petals had fallen, in anticipation of the March moth larvae. This moth does not appear before the end of February at the earliest, by which time it is considered dangerous to apply tar washes. The grower's only alternative is to keep the bands "sticky" on his trees to catch the female moths ascending, or to rely on a "pre-blossom" spray with arsenate of lead.

This loss of foliage to the trees must consequently have a very serious result and every endeavour should be made to get the trees to make some growth. In the first place the trees should be cleansed with some soapy mixture to which has been added a little nicotine (chiefly to rid the trees of Apple sucker and aphis, as the caterpillars are, by this time, pupating in the ground), and the soil to the full extent of the tree's roots should receive a thorough soaking of clear water. Nitrate of soda or sulphate of ammonia may be applied advantageously now to encourage wood and leaf growth and, later on, an application of superphosphate and potash should be given to bring about firmness and early maturity in the young wood. *H. H. C.*

HOME CORRESPONDENCE.

Vacation Employment for Undergraduates.—The enormous extension of facilities for University education in England has produced a phenomenon strange to us, but familiar enough in the United States and Canada, and not unknown even in Scotland. In America it is common for men and women undergraduates to spend their vacations in some form of paid occupation, thus enabling them to earn their keep during the summer months. In England this has been practically unknown, except for the few senior scholars who have coached the sons of the well-to-do for school or university examinations. There is a limit to the number of wealthy parents anxious for the mental attainments of their children and the number of opportunities for private coaching, never very great, is now quite inadequate to absorb the number of undergraduates from the old and the modern Universities, who come very often from lower-middle or working class homes, and who are anxious both to gain experience and to earn a living wage during July, August and September. Applications are now reaching us from undergraduates all over the country who wish to find such temporary employment. But in a country where this is not traditional, where are we to find the firms or persons who will offer them posts or consider their employment during a seasonal rush period. Generally, they are willing to do almost any kind of work, as labourers, shop assistants, waiters or waitresses, governesses and so on. Some of the senior science students might be capable of acting as works' chemists or physicists to replace staff on holiday. There is obviously a great number of ways in which they might usefully be employed to their own advantage and possibly also to the ultimate advantage of industry. We have every desire to avoid the displacement in any way of normal or regular labour, but if there are any employers who, while bearing in mind this cardinal point, might still be able to offer temporary employment to university men or women, we should be deeply grateful to hear of them. *Ralph Nunn May, Secretary, The National Union of Students*, 3, *Endsleigh Street, London, W.C.*1.

The "Gardeners' Chronicle of America."—The many readers of the American Horticultural journals on this side would rub their eyes when they read in your issue of June 15, p. 435, that your American namesake claims to be the only "all gardening" magazine in America. In turning the pages of the American magazine *Horticulture*, issued twice monthly, with Mr. Ernest H. Wilson, of the Arnold Arboretum, advisory editor, and including among its contributors W. N. Craig, T. A. Weston, T. H. Everett, Arthur T. Johnson, and other contributors to your columns, one can only wonder in what respect *Horticulture* is not an "all gardening" magazine. *Jonathan Fiona, Glasgow, S.*1.

SOCIETIES.

CHELTENHAM FLORAL FÊTE.

Readers of *The Gardeners' Chronicle* who are interested in our extracts from issues seventy-five years ago, will remember that the extract given a week ago referred to an exhibition held at Cheltenham. This is proof—if it were wanted—that fine flower shows are by no means new to the garden city of the Cotswolds. However, the old shows faded out, but seven years ago there was an extraordinary revival or resurrection of interest, thanks largely to the influence of the late Mr. John Cypher. The local Chamber of Commerce took the matter in hand, quite rightly assuming that a great flower show would be an additional attraction to, and a fine advertisement for the town. Mr. Cyril Cassidy is the Hon. Secretary, and much of the success already achieved is due to his untiring energy and organising ability. The Mayor and Corporation smile on this horticultural effort and loan the Montpellier Gardens as a show site—a beautiful site and practically in the centre of the town.

The show held on June 19 and 20 was a fine one, and hardy flowers of all kinds, Roses, stove and greenhouse plants, Carnations, Sweet Peas and table decorations were displayed extensively, while the trade groups were a host in themselves.

Special Awards.

The *John Cypher Memorial Cup*, offered for the best exhibit in the show, was awarded to Messrs. Sutton and Sons, for a beautiful exhibit of well-grown Sweet Peas, arranged in bouquets raised above a setting of cool moss studded with excellent Gloxinias. A few pots of Lobelia tenuior lent a touch of grace and colour that was very pleasing.

The *Cavendish Cup*, offered for the second best exhibit, was won by Messrs. James Cypher and Sons, with a large group of the stove and greenhouse plants for which this firm has long been famous. Having won this award on three occasions, the Cup now becomes the property of Messrs. James Cypher and Sons.

The Grocers' Cup, offered for the best display of Roses, was awarded to the Madresfield Gardens, Ltd., Malvern, for a well-planned Rose garden in which the value of Polyantha varieties was admirably demonstrated.

The *Master Builders' Cup*, offered for the best display of Sweet Peas, was won by Mr. J. Stevenson, Wimborne, with a bright display that included the varieties Model, Jay, Yadil, Bullion, Pinkie, Magnet, Wild Rose, Charming, Purity and Treasure.

The *Drapers' Cup*, offered for the best collection of hardy flowers, was won for the third time in succession by Mr. W. H. Walters, Colesborne, and it therefore becomes his property. Mr. Walters showed Primula Florindae in fine style, Polygonum alpestre, Meconopsis Baileyi, Roscoea cautleoides, Rheum Alexandrae, Irises and many other choice things.

The *Sunningend Cup*, offered for the best display of Carnations, was again won by Messrs. C. Engelmann, Ltd., Saffron Walden, and now becomes their property. This firm showed big sheaves of fine flowers of Laddie, Topsy, Ceres, Mrs. C. W. Ward and Sunny Boy.

The Gardeners' Chronicle Medal was awarded to Mrs. C. V. Butler (gr. Mr. A. J. Collins), Twyning Park, near Tewkesbury, for her first prize group of plants in the amateurs' section.

Competitive Classes.

Messrs. Prior and Son led in the large class for a display of Roses, with a bold and effective exhibit of sheaves and bowls of good blooms. Shot Silk, Etoil d'Holland, Geisha, Allen Chandler and Betty Uprichard were outstanding varieties. Mr. H. Drew, Longworth, Berks., came second, and showed Isobel, Shot Silk, Betty Uprichard and Lady Hillingdon, in good form.

A brilliant and educational display was made by the several competitors in the class for a collection of hardy perennial plants and cut blooms arranged in a space twenty-five feet by six feet. The first prize of £10, presented by the Corporation of Cheltenham, was won by Mr. G. F. Gullick, Salisbury, with a bold, tastefully arranged group of well-grown hardy flowers that included Gypsophila Bristol Fairy, Lilium monadelphum, L. croceum, L. Martagon, and L. umbellatum, Heucheras, Lupins, Delphiniums, Irises and Eremuri; second, the Gayborder Nurseries, Malvern; third, Messrs. Bowell and Skarratt.

The best rock garden or rock and water garden arranged on a space twenty-five feet by five feet, was the one produced by Messrs. Bowell and Skarratt, whose rocks were pleasing and well disposed, while their pool of Nymphaeas bordered by Mimuluses, was a delight, and Saxifrages, Violas, Primulas, Dianthuses and many choice alpines were pleasingly arranged on either side of a tiny alpine path; second, Messrs. J. C. Wheeler, Ltd., Gloucester; third, Mr. R. S. Milford, whose arrangement was a trifle flat, but contained some excellent Aquilegias, Primulas and Saxifragas.

Several artistic groups of plants were arranged in the class that allowed a display on a space of one hundred square feet. The chief award was won by Mrs. C. V. Butler (gr. Mr. A. J. Collins), Twyning Park, near Tewkesbury, with a capitally arranged group of well-grown Codiaeums, Dracaenas, Clerodendron fallax, Lilium regale, Carnations, Palms, Odontoglossums, and small Coleuses; second, Miss H. Huntingdon (gr. Mr. E. C. Pullen), Pershore, who showed Gloxinias and Hydrangeas extensively; third, Colonel Harford (gr. Mr. G. F. Clift), Cheltenham.

The Misses Fawkes were the most successful exhibitors of a dozen vases of hardy flowers, while Mrs. Mitchell led for six vases. Delphiniums were best shown by Mr. W. C. Blakeney; Lupins by Mr. A. Moore; exhibition Roses by Mr. F. Trinder; decorative Roses by Mr. R. Greshon and Mr. B. A. Bowers; Sweet Peas by Mr. H. Bates, Charlton Kings; and a group of one kind of garden flower, by Mr. W. C. Blakeney. The best display of hardy flowers, on a space twelve feet by four feet, was arranged by Captain H. Berford Pim, who had good Paeonies, Irises, Liliums, Anemones, Pansies and Ramondias; second, B. A. Bowers, Esq. (gr. Mr. F. Merriman), Cheltenham.

Floral Decorations.

The table decorations, in three classes, filled a large space and created a great deal of interest; the competition was very keen. These classes were open only to ladies.

In a class where any kind of flowers were permitted, Miss G. Bould, Cheltenham, led with a delightful arrangement of Sweet Sultans, Laelio-Cattleyas, Schizanthuses and Codiaeum leaves; this prize included the Martin Challenge Bowl; second, Miss G. M. Gillet, Dumbleton, who made effective and graceful use of small Oncidium sprays, Streptosolen Jamesoni, Kalanchoe, Echeveria sprays and cream-coloured Lupins; third, Mrs. R. C. Pownall, whose cool and novel design in Water Lilies, sedges and grasses, attracted a great deal of attention by reason of its departure from the orthodox. The lady, however, was not quite logical in the use of Maidenhair Fern and Asparagus—in the absence of these she might have won a higher position.

Miss G. M. Zelly, Winchcombe, won in the class for Sweet Peas only, with mauve and pink flowers; Miss E. J. Jones, second, with cream and lavender flowers; and Miss A. Yates, third, with mauve and cream flowers.

For a table decoration in Roses only, Miss A. Yates, Warminster, led with a fine display of yellow Roses; Mrs. Colston Hale, second, with Polyantha and large varieties; Mrs. J. Nixon, third, with yellow and pink blooms.

In the local class for table decorations, the prize winners were Miss G. Bould, Mrs. L. A. Rowley and Miss E. L. Jones, respectively; the first-named used pink Carnations and sprays of Plumbago capensis very effectively.

Non-competitive Groups.

As indicated, the trade growers turned up in force and produced a very fine effect. The following medals were awarded.

Large Gold Medals.—To Messrs. Sutton and Sons, for Sweet Peas and Gloxinias; Messrs. James Cypher and Sons, for stove and greenhouse plants and Fuchsias; and to the Madresfield Gardens, Ltd., for a Rose garden.

Gold Medals.—To Messrs. Hopwood, for a formal and trellis garden and hardy flowers; Messrs. James Kelway and Son, for Paeonies and Delphiniums; Messrs. W. H. Simpson and Son, for Lupins; Mr. W. H. Walters, for choice hardy plants; and to Mr. W. Wells, junr., for Delphiniums and other hardy flowers.

Silver-gilt Medals.—To Mr. C. Wall, for Carnations and Aquilegias; Messrs. Blackmore and Langdon, for Begonias and Delphiniums; Messrs. Toogood, for Irises; and to Mr. Coville, for Hydrangeas and other greenhouse plants.

Large Silver Medals.— To Messrs. Hewitts for Irises and Delphiniums; Mr. Barnfield, for Hydrangeas; Messrs. Maxwell and Beale, for hardy flowers; Mr. Harron, for Carnations, etc.; Mr. W. T. Payne, for Sweet Peas; Mr. H. Clarke, for hardy flowers; Messrs. Rich and Cooling, for hardy flowers; Mr. J. Milburn, for hardy flowers; and Messrs. Jarman and Co., for hardy flowers.

Silver Medals.—To Madresfield Gardens, Ltd., for Hydrangeas; Mrs. V. Fawkes, for floral paintings; Miss Marguerite, for floral designs; Mr. H. Beckitt, for hardy flowers; Messrs. J. White and Son, for hardy flowers; Messrs. Lowe and Gibson, for Irises; Messrs. Zambra, for hardy flowers; and to Mr. Herbert, for florists' and garden Pinks.

GUILDFORD AND DISTRICT GARDENERS'.

A party of about ninety members spent an enjoyable afternoon on June 15, when a visit was paid to the gardens of Mrs. Joicey, Sunningdale Park, on the borders of Berkshire. We believe these gardens had not previously been opened for such a visit. Mr. J. Dickson received the party on behalf of Mrs. Joicey, and with him was Mr. J. Mackay, gardener to J. J. Joicey, Esq., of Witley.

Sunningdale Park is beautifully situated, of great charm, and in altogether delightful surroundings. One visitor declared it to be the most beautiful place the Association has ever visited—which is saying a good deal.

The mansion of white stone, with fluted columns, stands on an eminence and commands pleasing views of the lawns and trees. From the front of the house the view is still more entrancing. Upon a terrace just below the lawn, rambler Roses are trained over a double row of arches, rising one above the other; below, there is an extensive rock garden in which boulders have been cunningly arranged to give the whole a natural appearance; and at the bottom is an ornamental Lily pond of considerable extent. Beyond the water the pleasure gardens rise again, and the lawns are studded with flower beds and specimen trees, including Deodar Cedars, Sequoias, Sophoras, Picea pungens, golden Cupressus and others.

The glasshouses were well filled with a wide range of subjects—Peaches, Strawberries and Melons were temptingly ripe, with others coming along in succession. In one house the Grapes were remarkable for the uniformity of size and shape of all the many bunches of fruits. Those devoted to flowers were equally attractive. Streptocarpuses, Hydrangeas and Calceolarias were particularly good. There was also a fine collection of Carnations, Bessie Greenfield, bright scarlet, being conspicuous. One house was devoted to old-fashioned plants, such as Clarkias, Pelargoniums, Calendulas, etc., and a striking feature in every house was a fringe of Lobelia.

Mrs. Joicey generously provided tea, which was served in a marquee erected in the park. Mr. Patrick, the President, expressed the thanks of the visitors to the venerable lady for permitting the visit and for her generosity; thanks were also extended to Mr. Dickson for giving up his afternoon and compliments were paid him on the condition of the gardens. Mr. Mackay was congratulated upon the honour recently won at the Chelsea Show, in securing for J. J. Joicey, Esq., a cup for Orchids, won outright.

On the return journey a halt was made at Virginia Water.

The next outing is to Sir Richard Garton's garden at Lythe Hill, Haslemere, on July 13.

ROYAL HORTICULTURAL.

June 25 and 26.—There was a very good show at this fortnightly meeting of the Society in the new Horticultural Hall, Westminster. While Paeonies, Delphiniums and Lupins were the hardy flowers most freely shown, there were also plenty of other seasonable border flowers and alpines exhibited, and several interesting collections of greenhouse plants. The Floral Committee recommended six Awards of Merit to novelties. Orchids were not quite so numerous as of late, and there was no novelty worthy of award. Vegetables were represented by a good collection of Lettuces, but beyond this, the members of the Fruit and Vegetable Committee found nothing to occupy their attention.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Prince Shimadzu, Sir J. Rutherford, Mr. Fred J. Hanbury, Mr. Lionel de Rothschild, Mr. R. G. Thwaites, Mr. T. Armstrong, Mr. J. Cowan, Mr. Charles H. Curtis, Mr. H. H. Smith, Mr. H. G. Alexander, Mr. J. E. Shill, Mr. A. Dye and Mr. F. E. Dixon, a visitor from the American Orchid Society.

Few Orchids were shown on this occasion, but it must be acknowledged that the Orchid growers have supported the fortnightly meetings nobly this season. Few novelties came before the Committee, but no awards of any kind were made.

Groups, etc.

Frederick J. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead, had a pretty exhibit that contained the red Epidendrum prismatocarpum, a fine plant of Cypripedium Miss Faith H. Hanbury, Laelio-Cattleya Capulet, L.-C. Miss Faith Hanbury, Miltonia Kennie, M. vexillaria var. Snowflake, Dendrobium acuminatum and several capital hybrid Odontoglossums.

Messrs. Cowan showed Cattleya Model—a fine flower, Odontioda Grenadier, Cypripedium Curtisii, C. C. var. Sanderae, C. A. de Lairesse, and the large-flowered Odontoglossum Gloriette.

Messrs. Black and Flory staged a beautiful group of Miltonias, their leading sorts being M. Charlesworthii, M. Lyoth, M. Kennie in variety and M. Venus. The plants were nicely grown and prettily arranged, but a few Ferns on the staging would have provided a more pleasing effect. Messrs. Stuart Low and Co. contributed a few Orchids, including Phalaenopsis Luedemanniana, Miltonias, Odontoglossum Williamsianum, Laelio-Cattleya Aphrodite and Epidendrum Medusae, with two of its curious flowers.

F. Mercer, Esq. (gr. Mr. Bond), Clovelly, Steyning, showed a large Miltonia vexillaria carrying a score of spikes; had the spikes been staked out more widely the specimen would have looked more elegant, instead of crowded. The old Odontoglossum apterum was shown by Messrs. Sanders, who also exhibited the rare Lycaste tricolor.

Floral Committee.

Section A: *Present:*—Mr. Henry B. May (in the chair), Mr. G. W. Leak, Mr. J. F. McLeod, Mr. A. Turner, Mr. C. E. Pearson, Mrs. E. Wightman, Rev. Rollo Meyer, Mr. Courtney Page, Mr. M. C. Allwood, Mr. J. B. Riding, Mr. W. B. Gingell, Mr. J. M. Bridgeford, Mr. W. Howe, Mr. David Ingamells, Mr. D. B. Crane, Mr. George Churcher, Mr. R. Findlay, Mr. E. R. Janes, Mrs. Lindsay Smith and Mr. W. D. Cartwright, Secretary.

Section B: *Present:*—Mr. C. T. Musgrave (in the chair), Mr. G. Yeld, Mr. J. Hudson, Mr. G. Reuthe, Mr. G. Harrow, Mr. A. Bedford, Mr. Amos Perry, Mr. R. Cory, Mr. J. Comber, Mr. F. G. Preston, Mr. Mark Fenwick, Mr. E. H. Wilding, Mr. W. B. Cranfield, Mr. L. R. Russell, Mr. E. Marsden-Jones, the Marquess of Hartington, Mr. C. Williams, Mr. T. Hay, Sir William Lawrence, Bart., Mr. G. W. E. Loder and Mr. N. K. Gould, Secretary.

Awards of Merit.

Lobelia The Marvel.—A grand plant for bedding purposes or for pot culture, of compact and bushy habit and very free-flowering. The plants shown were about ten inches high and were laden with double, rich blue flowers. Shown by Mr. Philip Ladds.

Rose Duchess of Atholl.—The flowers of this grand Rose are of perfect shape and rich reddish-orange in colour, the bases of the petals and the outer ones being of rather lighter shading. Shown by Messrs. Dobbie and Co., Ltd.

Streptanthera cuprea.—A delightful little South African member of the Natural Order Irideae, attaining a height of about six inches, in foliage similar to a dwarf Tritonia. Its flowers, which are about one-and-a-half inch in diameter, are pale terra-cotta, with a central purplish zone edged with dark bands. A very bright and attractive subject. Shown by Mr. Amos Perry.

Rhododendron Houlstonii.—A single truss of this beautiful Rhododendron was shown. It was compact, and the individual flowers, about three inches across, were pale shell-pink in colour, daintily frilled and of good texture. Shown by E. M. Preston, Esq. (gr. Mr. C. F. Wood), The Warren, Hayes, Kent.

Pentstemon strictus.—This charming plant from North America was shown under the name of P. comarrhenus, which, according to *Index Kewensis*, is synonymous to the above. The flowering sprays shown were about two-and-a-half feet high, the smooth stems being furnished below the inflorescences with glaucous-grey, sagittate, clasping leaves. The flowers are rosy-lavender in colour, with paler tubes. Shown by Mr. T. Hay, Hyde Park.

Oenothera trichocalyx.—This beautiful species has very attractive, narrow, toothed, grey leaves with prominent white midribs, and large, pure white flowers shaded with primrose-yellow at the throat. Judging by the inflorescences shown, it would appear to be very free-flowering. Shown by Mr. T. Hay.

Cultural Commendation.

To Captain B. Symons-Jeune, for grand specimen plants of Saxifraga Tumbling Waters, with nearly twenty enormous drooping inflorescences, some of which were quite two feet in length.

For Trial at Wisley.

Delphinium Blue Gem.—An extremely handsome, tall, branching spike of large, vivid blue flowers. Shown by Messrs. Blackmore and Langdon.

Antirrhinum Sutton's Gem.—A new, distinct strain of dwarf Antirrhinums, obtained by crossing A. glutinosum with bedding sorts. The plants are of dwarf, spreading and bushy habit, forming close mounds of blooms. Several colour forms have been obtained, Pale Apricot and Pale Pink being exhibited as splendid pot plants.

Groups.

Carnations were shown in very good quality. Immediately inside the hall, Lady Emsley Carr (gr. Mr. J. T. Doe), Wonford, Walton-on-the-Hill, exhibited an uncommonly good group of floriferous plants. Their customary collections of cut blooms were staged by Messrs. Allwood Bros., Messrs. C. Engelmann, Ltd., and Messrs. Stuart Low and Co. The last-named also showed a small collection of greenhouse plants. Messrs. B. Ladhams, Ltd., filled a small table with very good border Pinks, and Messrs. Hayward and Son also staged border Pinks. Messrs. Chaplin Bros. included their new variety Pink Climber in a collection of Roses, and Mr. J. H. Pemberton had a pleasing exhibit of H.T. varieties.

In the centre of the hall, Messrs. Carter and Co. set out a handsome circular group of Clerodendron fallax and well-coloured Coleuses. The Clerodendrons were sturdy plants, which evidenced first-rate cultivation. Mr. T. Bones showed several interesting varieties of dwarf Lobelia. Mr. H. A. Brown had a selection of greenhouse Fuchsias of useful sizes. The Rolvenden Nurseries again had a very large exhibit of their excellent Statice profusa var. superba, and Messrs. J. Cheal and Sons had early Dahlia blooms.

On a wall space, Messrs. Sutton and Sons set out an exceedingly interesting and valuable collection of Godetia seedlings. These were mostly of tall habit and bearing plenty of large flowers of pleasant colouring. They also included exceedingly dwarf plants of Antirrhinum Sutton's Gem, a Pale Pink, and Pale Apricot.

A very effective hardy flower exhibit was arranged by Messrs. B. Ladhams, Ltd. This was in the form of an herbaceous border, enclosed on three sides by a trim Yew hedge. The chief plants were Paeonies, Campanulas, Trollius and Gaillardias, with a small pool of Nymphaeas. Messrs. L. R. Russell, Ltd., also had a small pool of hardy Nymphaeas, and associated them with a rock garden planted with Sempervivums. At one end, they had various border flowers. Messrs. Waterer, Sons and Crisp had a large exhibit of Philadelphuses and many hardy plants, including Oenotheras, Erinus and other alpines. Messrs. Stuart and Son staged Iceland Poppies, Sweet Peas and border plants.

The decorative value of Saxifraga Tumbling Waters was well shown by Captain Symons-Jeune, who had excellent plants in a large brass vase. Campanula Pride of Exmouth was shown with Heucheras by Messrs. Hollambys. Messrs. Bakers staged various Primulas, Lupins and Delphiniums. In a neat rock garden, Messrs. Maxwell and Beale planted dwarf Rhododendrons and alpines. Messrs. Pulham and Son had a sandstone rock garden, and Mr. J. Robinson set out Saxifrages, Thymes, Primulas and Pinks in a Cumberland stone rock garden, while Mr. G. E. P. Wood planted Violas, Linarias, Pinks and other lovely plants. The Misses Hopkins showed border flowers.

Many interesting and decorative species of Alliums were grouped by Mr. Amos Perry, with Liliums and other plants. The Liliums included L. Martagon var. album, L. tenuifolium and L. Thunbergianum var. maculatum.

A large collection of Irises, Lupins, Liliums and Nepeta Mussinii was arranged by Messrs. Wallace and Co. Messrs. Patricks had a square group of Conifers and flowering shrubs. Mr. R. C. Notcutt grouped Brooms, Spiraeas, Escallonias, Potentillas and other shrubs. Messrs. C. H. Bloom and Son and Mr. Gavin Jones showed various border flowers. At the far end of the hall, Messrs. Dobbie and Co. set out sturdy, floriferous pot plants of dwarf Bush Balsams, with a few vases of the gorgeously coloured H.T. Rose Duchess of Atholl.

Delphiniums were shown extremely well by Messrs. Blackmore and Langdon, their finest sorts, in huge sheaves, being Purple King, Blue Bird, Lady Gwendolin, Constance, Norah Ferguson, Mrs. Foster Cunliffe, Lady Elizabeth and Lady Eleanor. Messrs. Kelway and Sons showed many good sorts in their extensive collection of Delphiniums, as also did Messrs. Hewitts, Messrs. Chaplin Bros., Ltd., and Messrs. R. H. Bath, Ltd., the last-named including several choice Paeonies in their display.

Paeonies were shown in grand style by Messrs. George Bunyard and Co., Ltd., their large bank of blooms including such good sorts as Alsace, Amathea, Madame d'Galtha, La Perle, Henry Demay and Lorraine, while outstanding Paeonies in the collection from Baggesen's Nursery were festiva var. maxima, Princess Matilda, Madame Calot and rubra var. triumphans.

Messrs. G. W. Miller had a small group of Paeonies, Pyrethrums and Heucheras in variety, while Messrs. Barr and Sons, in their mixed group, had large sheaves of Canterbury Bells, Paeonies and bulbous Irises, together with Gaillardias, Erigerons, Armerias and Nepeta.

Messrs. Kelway and Sons staged a collection of choice Paeonies, striking among which were Kelway's Lovely, Una Howard, Superba, Cyclops and Boule de Neige; while Messrs. L. van Leeuwen and Son, Ltd., also displayed an extensive collection of these seasonable flowers.

W. CUTHBERTSON, Esq., Duddingston, Midlothian, showed some giant inflorescences of several tall, bearded Irises, those of Bruno being simply magnificent, for the large, richly-coloured blooms were carried on stout stems three feet or more high.

From the R.H.S. GARDENS, Wisley, came flowering sprays of Buddleia alternifolia, Diervilla rosea var., and Pyracantha Rogersiana, the last-named demonstrating well the remarkable floriferousness of this shrub under congenial conditions.

Fruit and Vegetable Committee.

Present: Mr. J. Cheal (in the chair), Mr. W. H. Divers, Mr. Edwin Beckett, Mr. F. Jordan, Mr. A. Poupart, Mr. E. Neal, Mr. W. Poupart, Mr. P. A. Tucker and Mr. A. N. Rawes, Secretary.

GROUPS.

The only exhibit which the Committee had to consider was a collection of splendidly grown Cabbage Lettuces, of several distinct types and varieties, set up by Messrs. SUTTON AND SONS. Two good sorts with bronzed foliage were Satisfaction and Marvel; Favourite and Drumhead were noteworthy among those with crinkled foliage, while firm-hearting sorts included Veitch's Golden Queen, Golden Ball, Standwell, Improved Tom Thumb, All the Year Round, Matchless and Commodore Nutt.

CARDIFF GARDENERS'.

THE second Saturday afternoon outing of the season was held on June 15, when many members and their wives travelled by charabanc to Llantwit-Major, where an enjoyable picnic was held. The first stop was at Nash Manor, near Cowbridge, and through the kindness of Captain and Mrs. Carne, the party was conducted through these old-fashioned gardens. One of the chief features was the old Rose garden, where the beds are ornamentally encircled by well-kept Box edgings. Some ancient specimen Rose trees, estimated to be at least fifty years old, growing in these beds, were of great interest. The kitchen and fruit gardens were visited also. The party then proceeded to Llantwit-Major, where an enjoyable and interesting evening was spent.

ANSWERS TO CORRESPONDENTS.

NAMES OF FRUITS.—*A. M. S.* 3, Apple, probably Bismarck; 4, Apple, probably Bramley's Seedling. The spurs show signs of frost damage. Illustrations showing the effect of frost on the foliage of Apple may be found in *The Gardeners' Chronicle* of August 20, 1927 (p. 154).

NAMES OF PLANTS.—*K. Y.* Erodium malacoides; Rehmannia angulata.—*A. M. S.* 1, Taxus baccata, very like var. fastigiata; 2, apparently Taxus baccata var. horizontalis; 5, Sedum Sieboldii var. variegatum; 6, Iberis sempervirens; 7, I. sempervirens var. Garrexiana; 8, Asperula odorata, the Woodruff.—*J. P.* Tamarix tetrandra.—*D. I.* Pyrus torminalis, the Service Tree.—*H. B.* 1, Silene inflata (Catch-fly); 2, Hieracium aurantiacum var. rubrum; 3, Haemanthus albiflora.—*W. D.* 1, Achillea rupestris; 2, small specimen, but appears to be Achillea conjuncta; 3, 4, 5, Dianthus (cannot name garden hybrids); 6 to 11, small specimens, but all appear to be forms of Phlox stellaria.—*G. R. T.* Lycaste cruenta.—*Hortus.* 1, Syringa villosa; 2, Neillia opulifolia; 3, Ulmus campestris var. Louis van Houtte; 4, Acer platanoides var. maculatum; 5, Fraxinus Ornus, the Manna Ash; 6, Amelanchier canadensis; 7, Caragana arborescens; 8, Ulmus viminalis var. aurea; 9, Ulmus montana var. purpurea; 10, Ulmus nitens.

REMARKS.—Supplies throughout this department have shown a general increase during the past week, especially among the outdoor blooms. Blue Irises are still a tremendous glut, and inferior grades are difficult to clear. White and yellow Irises, although in good demand, vary somewhat in quality and price. Gladioli are in excellent condition in various shades of pink, deep red and white. The Gandavensis Gladioli consists of The Bride, Blushing Bride, Peach Blossom, Nymph and Ne Plus Ultra. Carnations and Roses have shown a considerable increase in supplies, and the former are at the lowest price so far this season, although the demand for both has been good generally. Other prominent lines are Coreopsis, blue and pink Cornflowers, Delphiniums, Gaillardias, Gypsophila elegans, now in excellent condition; Lilium longiflorum, Nigella, Paeonies, from home-growers, Scabiosa caucasica, Stocks, double white, mauve and pink; Sweet Sultans, white and mauve; and Marigolds (Orange King). Sweet Peas are still somewhat varied in quality and all best grades are soon bought up at prices similar to last week's quotations. Pyrethrums are practically over for the season. Mrs. Sinkins Pinks are too numerous for present requirements, the variety Her Majesty being preferred because of its finer blooms which last longer and reach the market in a sounder condition.

In the pot plant department business continues very active, the bedding season now shows signs of finishing. Most growers have practically cleared their stocks. Plants such as are required for decorative purposes are still in good demand, the newest arrivals being Viscarias, blue and pink, some very fine Marguerites, and Verbenas in forty-eight's, also Polyantha Roses.

Vegetables: Average Wholesale Prices.

REMARKS.—In spite of the comparatively large quantities of Strawberries available, most departments report active conditions. In the hothouse fruit section, supplies generally are on the increase, and any reductions in price levels are due mainly to that reason. Supplies of English Cherries have been heavier, and values have declined. Italy is sending some heavy consignments of very handsome Cherries to London, against which our own produce looks rather poor, but these imported Cherries will cease to arrive by the week-end. Strawberries are plentiful and making good money, the recent weather being entirely favourable for their consumption. Gooseberries have been a fair market, except for very small berries, which are practically unsaleable. Tomato prices are firm and although quantities are fairly heavy, values are being maintained at good levels. Cucumbers are quoted at easier prices; probably the cheapness of other salads, principally Lettuces, is having its effect on Cucumber prices. Although the recognised date for the finishing of the Asparagus season is past, there is still a fair sprinkling; but Peas are now so reasonable in price that any Asparagus other than "Giant" is selling slowly. Mushrooms, owing to the heavy supplies and poor demand, are a weak section, but some improvement here is expected. French Beans are still doing well, although some are beginning to show signs of being past their best. New Potatos are comparatively cheap, and neither Jersey nor St. Malo produce is making much money; the few English Potatos are doing rather better.

GLASGOW.

Low prices and plentiful supplies stimulated business in the cut flower market last week. Carnations ranged in price from 1s. 6d. to 3s. per dozen; Roses, 2s. 6d. to 3s. 6d.; large-flowered Gladioli (Prince of Wales, etc.), 1s. to 1s. 6d. for 6's; small-flowered, 6d. to 10d. per dozen; Sweet Peas, 3d. to 1s. per bunch; Irises, 10d. to 1s. for 12's, and 2d. to 8d. for 6's; Paeonies, 1s. to 2s. for 12's; Anemones, 1s. 6d. to 2s. 6d. per dozen bunches; Lily-of-the-Valley, 1s. 9d. to 2s. 9d. per bunch; Nigella, 8d.; double Stocks, 1s.; Lupins, 3d., and Cornflowers, 2½d. Richardias were exceptionally cheap at 1s. 6d. to 2s. 6d.

The fruit market was more active than it has been of late, and Strawberries were in good demand at 8d. to 1s. per lb., with selected Southampton fruits at 1s. 6d. Home-grown Grapes sold at 2s. 9d. to 3s. per lb.; Melons, 3s. 6d. to 5s. each; Peaches, 1s. to 1s. 3d. each; English Cherries, 5s. (6 lbs.); Apricots, 10s. 6d. per box; Gooseberries, 3d. to 5d. per lb.; and Gages, 12s. 6d. to 15s. (22 lbs.). Apples were dearer at 17s. to 20s. per case for Jonathan, and 17s. to 18s. for Sturmer Pippin; Winter Nelis Pears realised 10s., and Grape Fruits, 40s.

Vegetable prices were steady, except for Asparagus, which declined in value to 10d. for small bunches and 2s. for large. Scotch Tomatos were worth from 10d. to 1s. 2d. per lb.; Lettuces, 1s. to 2s. 6d. per dozen; Cucumbers, 5s. to 7s.; Peas, 6s. to 8s. per boat; Beans, 1s. 6d. to 1s. 8d. per lb.; Rhubarb, 4s. to 5s. per cwt.; Radishes, 1s. 6d. per dozen bunches; Syboes, 3d. to 5d; Carrots and Turnips, 10d. to 1s.; and Mushrooms, 1s. 6d. to 2s. per lb.
